At the invitation of the minister of transport a special committee of the British Medical Association consisting of some fifteen eminent physicians and surgeons has been studying the relation of alcohol to road accidents. Its report has now been presented. It concentrated on the effects of amounts of alcohol insufficient to produce what might be called drunkenness. Small amounts of alcohol lead many persons to make rapid decisions less judiciously than they otherwise would. To what extent this is responsible for automobile accidents there is no means of estimating, but it is a serious objection to the taking of alcohol, even in small amounts by any one who is to drive a car. Amounts corresponding to 2 or 3 ounces of whisky usually affect adversely the power of rapid and accurate coordination. At the same time the person may believe himself to be driving better. Last year 2,016 automobile drivers were certified by a physician to be under the influence of alcohol. It is beyond dispute that they were a potential source of accidents. But there must be a much larger number of drivers who would not be so certified and yet have their driving powers impaired by alcohol.

This report of the committee of the British Medical Association has produced considerable resentment among motorists who declare that the conclusions are too sweeping. An official of the Automobile Association said: "These scientific deductions, while valuable in their own sphere, have no legislative weight. In some cases a stimulant may be beneficial to a motorist who is tired and may improve his driving ability."

Nutrition and Public Health

The League of Nations has issued a bulletin entitled "Nutrition and Public Health," by Edward Burnet and W. R. Aykroyd. No country in the world, it is stated, can claim that the whole of its population is satisfactorily fed. Poverty is mainly to blame, ignorance to a less extent. The so-called protective foods, richest in minerals and vitamins—milk, green vegetables, fresh fruit, eggs—are also the most expensive and in all countries are beyond the means of great masses of the population. The report alleges that in Great Britain between 10 and 25 per cent of the population cannot afford a diet of

the type and quality now known to be essential as a safeguard against malnutrition and disease." The existence of a group that could afford a complete diet but do not secure it, because of ignorance, is admitted. The report also claims that more than 22 per cent of the children in the United States investigated up to 1924 showed symptoms of malnutrition. "The fact that the greater part of the population of Africa and Asia suffer from insufficient and faulty feeding is no longer a secret."

While a world wheat surplus threatens economic stability, pellagra and beriberi, both diseases which consumption of wheat would eliminate, continue to take thousands of lives every year. One of the greatest needs of modern statesmanship is that governments seeking to dispose of food and governments needing such for the health of their citizens should find some basis of agreement.

In reply to the allegations and conclusions of this report it may be pointed out that the chief medical officer of the ministry of health has stated that the nutrition of the people of Great Britain is better than in any period of which there is record. Also the export of food is not a matter of government arrangement but of business. The surplus wheat of America can be brought to the doors of the millions of Asia and Africa only by payment of the cost of the article and its transport from the farm to the coast across thousands of miles of ocean and then again up country. In many cases the natives could not pay a fraction of this cost if indeed they are not in totally inaccessible places. The truth is that primitive and backward peoples must necessarily live on their local produce.

Report of Committee of House of Lords on Osteopaths Bill

The collapse of the osteopaths' attempt to obtain registration was reported in a previous letter. The house of lords referred the bill to a select committee, an unprecedented procedure in the case of the bill of a private member. When eminent witnesses testified that osteopathy had no scientific foundation, the osteopaths could not face this issue and withdrew their application, giving as the ostensible reason that the committee was not competent to try the issue. In spite of the withdrawal, the committee considered it a duty to report on the bill. The committee states that in all comparable cases of vocations for which a statutory register has been authorized three conditions have been fulfilled: 1. The sphere within which the vocation operates has been clearly defined. 2. The vocation has already long been in general use. 3. There has already been in existence a well established and efficient system of voluntary examination and registration. In the case of the osteopaths, none of these conditions have been fulfilled. No definition of osteopathy was included in the bill as introduced, and although one was subsequently proposed and others were suggested, none emerged which satisfactorily differentiated the osteopathic sphere of activity. Though widespread in the United States and Canada, osteopathy is carried on in the United Kingdom by not more than 2,000 or 3,000 practitioners, of whom only about 170 can claim to be "qualified." It is practically unknown on the continent of Europe. The only establishment in this country for the education and examination of osteopaths was exposed, in the course of evidence, as being of negligible importance, inefficient and, above all, in thoroughly dishonest hands. The only training ground for the qualified osteopath would be in North America, and it was pointed out by a representative of the ministry of health that "it is alien to the general principles which have so far been followed in comparable legislation to recognize qualifications which are conferred by foreign educational institutions." From the inquiry it emerged that osteopathy is not, as is popularly supposed, a craft limited to the treatment of maladies of bones, joints, muscles and ligaments by manipulation. In this sphere the committee has no doubt that qualified osteopaths perform valuable services.

Osteopathy claims to be a method of treating all diseases. The committee finds that this claim has not been established and therefore reports that it would not be safe to recognize osteopaths on a footing similar to that of physicians. The question of a register for osteopaths should be deferred until the sphere of osteopathy has been defined and a system of education in its principles and practice has been developed in one or more well equipped institutions.

This report is satisfactory in its condemnation of the ridiculous claims of osteopaths, especially as it is unanimous, although the committee contained avowed supporters of osteopathy. These evidently had their eyes opened. But in their limited commendation the committee makes the mistake of confounding osteopathy with bone setting. As stated previously in *THE JOURNAL*, the osteopaths have encouraged and taken advantage of this mistake. The committee in using the phrase "education in the principles and practice of osteopathy" shows that it is in need of further enlightenment as to the nature of this fantastic cult.

A Polished Floor Costs Hospital Thousands of Dollars

A widow when visiting her son, a paying patient in the Westminster Hospital, put her foot on a mat, which slipped on a polished floor. She fell on her side and as a result of the accident her left leg was an inch shorter than the other. The injury sustained is not described in the report but it appears to have been a fracture of the femur. She brought an action against the hospital, contending that it was negligent in having on a slippery floor a mat without taking steps to ensure that it would be stable when trodden on. She admitted that in 1911 all her toes except the big toes had been amputated, but she stated that this had not made it difficult for her to keep her balance or in any way interfered with her activities. The judge said that the hospital authorities must have known that the floor was highly polished and the secretary had said that it was kept highly polished for antiseptic purposes. They ought to have known that it was dangerous to place a mat on a highly polished floor and that it might slip. They ought to have secured the mat. He awarded damages of \$14,000.

The British Medical Association and Protection Against Chemical Warfare

At the representative meeting of the British Medical Association, held in London, three resolutions were submitted by the Kingston-on-Thames Division urging that instruction in anti-chemical warfare should be given to medical students that similar instruction should be available for postgraduates, and that, in view of the necessity for educating the public in measures of protection against chemical warfare, the British Medical Association should ask for the cooperation of its members. It was urged that in the event of this country being involved in conflict with a European power we would quickly be subjected to attack by airplanes with all sorts of incendiary and gas bombs. At present all countries on the continent are realizing this. Mr. H. S. Souttar, chairman of the representatives and surgeon to the London Hospital, stated that recently he and the medical secretary were invited to a conference at the ministry of health, at which many other educational bodies were invited, to discuss the matter. The ministry of health and the war office were fully alive to the necessity of educating the civilian population in the matter. The authorities wished to make use of the British Medical Association for the purpose. Through their divisions they were in an exceptional position for diffusing the necessary knowledge among the physicians of the country. Every conceivable precaution would be taken to insure that the medical and nursing services of the country and the civilian population were trained in those matters. The resolutions were carried.

On behalf of the North Glamorgan and Brecon Division a resolution was then moved that the association should concentrate on the abolition of chemical warfare. An objection was made that it was not a political association. This was due to the fact that such resolutions generally emanate from socialists and extreme pacifists. The chairman, however, ruled that the resolution was not political. This resolution was carried and was referred to the council.

The Medical Work of the Mission to Lepers

The Mission to Lepers celebrated its diamond jubilee last year and has now published its sixtieth annual report. On the medical side larger numbers than ever have received special leprosy treatment and the results are as encouraging as in previous years. At fifty different stations—in India, China, Korea and Africa—9,157 patients were under treatment for not less than three months. Of these, 5,572 improved in varying degree and 1,413 were declared symptom free. Of the latter, 1,054 had arrested cases without deformity, and 704 were able to return to their own homes. Upward of 6,900 lepers were also treated as outpatients at the different homes. Injections of chaulmoogra or hydrocarpus oil and its derivatives continue to form the basis of most of the treatment. At some of the homes the patients under treatment have been trained to give injections and to act as nurses. More recently Christian ex-patients have taken charge of leprosy clinics in outlying villages. The constructive value of work among the children of lepers is being increasingly emphasized.

Standardized Dimensions for Hospital Wards

The Hospitals and Medical Services Committee of the London County Council has made a report proposing standardized dimensions for the wards of hospitals to be erected in the future. The committee stated that the standards in the past were mainly of cubic capacity and appear to have been based on such considerations as air pollution, about which there were no exact data. There was no real scientific foundation. The comfort and well being of the patient and his efficient treatment should be the determining factors. If these are provided for, all other considerations and theoretical formulas may be disregarded. The committee recommends a standard width of 26 feet for all wards in general hospitals. In wards for acute diseases (including maternity, tuberculosis, venereal and acute mental cases) the wall space per bed is to be 8 feet, height 11 feet up to a length of 50 feet and 12 feet above this length. In wards for chronic diseases the wall space per bed is to be 7 feet but for offensive cases 8 feet, the height is the same as for the wards for acute cases. In cot wards the wall space per bed is to be 7 feet with the height as before. Single-bedded wards are to be not less than 11 by 10 feet with a height of 10 feet, or in conformity with the general plan. The resulting cubic capacity is less than was formerly considered necessary, when importance was attached to the height of wards as providing additional air space and heights up to 16 feet were the rule. It is now known that any height above 12 feet does little or nothing for ventilation, which depends on adequate window space. No ruling as to length of wards is laid down but wards of 100 feet will probably not be constructed again.

Report on the Quetta Earthquake

The medical report on the Quetta earthquake throws new light on that appalling disaster. Col. A. J. H. Russell, public health commissioner, states that no fewer than 31,500 persons were evacuated from Quetta by rail. This suggests that previous official reports overestimated the death roll. In the early days of the disaster 2,500 dead were excavated. Assuming the original population of the city and cantonments to have been between 66,000 and 70,000, Colonel Russell infers that between 12,000 and 16,000 bodies lie under the ruins of Quetta city,

although he admits that these figures are mere approximations. In his opinion the general health arrangements are adequate for the protection of both the troops and the civilian population. He upholds the prompt action of the authorities in sealing up the city on health grounds. The whole population in the refugee camps has been vaccinated and inoculated against epidemic diseases. Experimental excavations of the debris will be conducted in order to determine whether a general clearance of the buried city may be proceeded with without danger to the 18,000 people still living in the vicinity. There are difficulties and dangers in excavating an area which is a veritable graveyard of thousands of human beings and animals. Colonel Russell considers it inadvisable to undertake exhumations on any extensive scale, because of the nuisance that would arise from the stench and flies. For health reasons alone he considers it unwise to recruit a large force of workers.

The Methodist Church and Spiritual Healing

For the first time in the history of Methodism, the question of spiritual healing was raised at the annual conference. The question has often been discussed at meetings of the Church of England. Rev. L. D. Weatherhead moved a resolution urging that a special committee be set up to consider the whole question of spiritual healing. Mr. Weatherhead, who has published a number of books on psychology, said that in a large number of people who were ill the trouble was not physical in origin and also not mental. It was spiritual in origin. Such people were not adequately treated by the physician or the psychotherapist. Many methods practiced under the heading of spiritual healing were not sound. Any method that was practiced must be one that would go hand in hand with the discoveries of medicine and surgery. A committee of physicians, ministers and laymen was wanted to find out what methods were sound, to correlate ideas, collect evidence, and see whether any valuable rapprochement was possible between their profession and the medical profession. The resolution was passed unanimously.

The Smell Society

The Smell Society has just been formed 'with the intention of restoring the sense of smell to the high position it holds among all higher animals other than man'. Its work will be to replace the unpleasant and noxious smells that civilization has introduced by the pleasant smells that have been lost. In a letter to the *Times* announcing the formation of this society, the writer assures readers that, though they may at present be mildly amused, the Smell Society will in a year's time be a powerful body. He says that the subject is a wide one and goes far beyond appreciation and pleasure into the realms of health. For instance, an essential part of good cooking is the fact that smell prepares the body for the reception of food. The *Times* takes the project seriously, devoting to it an editorial three fourths of a column long. The society proposes to make people more smell conscious. But here the difficulty begins, for many people prefer not to be smell conscious. There is the difficulty that civilization has brought with it so many bad smells that the disadvantages of being sensitive to smells will outweigh the advantages. But sanitation has left our cities smelling good because they smell of nothing.

Salaried Midwives

In considering methods of improving the midwifery service, the low earnings of midwives and the consequent attraction into that calling of an inferior class of women has received attention. One remedy proposed was the support by the state of salaried midwives. At a meeting of the London County Council it was decided to inform the minister of health that the council supported a recommendation to establish a salaried midwives service under the local authorities, subject to a satisfactory grant-in-aid from national funds.

Discontentment over Social Insurance Deficits

The social insurance law is now five years old, but from all sides come complaints that it has not proved to be the success that was expected. In attempting to balance its budget, the government has planned to save 400 million francs (about 25 million dollars) annually through economies in the administration of the law. One of the members of the chamber of deputies has asked for an emergency revision of the law because the premiums that insured workers are obliged to pay are a burden hard to bear. More than four billion francs (about 250 million dollars) is taken "out of the pockets of employers and employees every year and most of it is stowed away (thesaurized) in the sinking funds of the various organisms of the law," according to this legislator. The premiums must be reduced in line with a general effort to lower the cost of living in France.

Finally, in the *Sidèle médical* of recent date appears an article entitled 'a decisive change,' which states that one of the chief objectives of the social insurance law, an effort to prevent disease by better sanitary organization of the country, is at last in the first stages of fulfilment. One is also much concerned about deficits in the budgets of the primary distributing agencies, or "caisses," of the social insurance law. These collect the premiums from the employers and employees and disburse benefits for illness, maternity cases and deaths. These "caisses primaires" insure themselves in a sort of central government agency termed the 'Union of reinsurance.'

At a recent meeting of all of these reinsurance societies it was found that the "caisses primaires" were in a bad way financially and that surely next year, if not already this year, there would be deficits.

These "caisses primaires" during 1930-1931 distributed only 40 per cent of their income, whereas in 1934 the proportion rose to 89.5 per cent. The average premium dropped from 70 francs (\$3.75) a month in 1930-1931 to 63.7 francs in 1934, or about 10 per cent. This drop in revenue is more marked in the departments outside Paris than in the latter city. The reverse is true of the disbursements.

Out of 103 of the "caisses primaires" (primary collecting and distributing agencies) insuring 1,220,000 workers, thirty nine are in deficit for sickness insurance, seventeen for maternity insurance and nineteen for death benefits. These financial difficulties will be combated in the future by the Reassurance Union lending money on more liberal and longer terms to the caisses primaires. As stated in previous letters, one of the drawbacks to the present social insurance law is the thesaurization, i. e., keeping out of circulation vast sums of money by the central organizations which are constituted by the "Union of Reassurance" and by the 'guaranty fund.' The former is the custodian of sickness, maternity and death insurance premiums and the latter for old age insurance premiums.

These huge sums of money under the control of these "higher-up" links in the social insurance chain are not always wisely invested and there has been much open criticism of this feature of the law. The latter dates only from 1930 and it will be many years before those who are now paying for old age insurance will reach the age of 65 and demand reimbursement for sums paid in many cases over a period of from thirty to forty years. No secret is made of the criticism of the poor investments, entailing much loss of money, which have been made by the trustees of some of these funds.

The experiment in social insurance in France has been far less successful than was hoped or promised. The attitude of the medical profession is becoming more and more bitter in these days of crisis.

Hemiplegia Following Exploratory Puncture of Chest

At the May 10 meeting of the Société médicale des hopitaux, Sergent and his associates called attention to embolism as an accident in exploratory puncture of the chest. They reported a case in 1933 and now report a second case. One can best explain such a complication as being due to the entrance into the pulmonary circulation of an embolus composed of blood mixed with air, as demonstrated experimentally by Komis and others.

In Sergent's second case, an exploratory puncture was made preliminary to operation for a pulmonary abscess, following removal under anesthesia of infected teeth. The embolism occurred during the second step of the drainage of the abscess, adhesions having been established during a first intervention under local anesthesia four days previously.

Immediately after exploratory puncture of the exposed lobe containing the abscess and withdrawal of a bloody, frothy fluid, a right hemiplegia with aphasia, right conjugate deviation and amaurosis appeared. All these symptoms disappeared during the three days following the exploratory puncture. One can best explain such accidents by the existence of a simultaneous injury of a bronchus and a pulmonary vein and the transportation of an embolus composed of blood and air.

A vascular spasm of the left sylvian and right posterior cerebral arteries is believed by Sergent to have played an important part in the brain symptoms as the mechanical obliteration of the vessels by the embolus.

In the discussion, Justin Besançon reported some experimental work on dogs which confirmed the role of vascular spasm. Following embolism of the vessels of the right eye one finds a bilateral spasm of the retinal vessels, which extends to the cerebral vessels. One can eliminate these vascular spasms by the injection of choline, so as to be able to study the effects of the embolism alone.

Hillemand reported a case of jacksonian epilepsy ending fatally following exploratory puncture.

Dr Harvier Elected Professor of Therapeutics

Dr Harvier until recently associate professor of therapeutics at the Faculté de médecine, has been named professor to succeed Professor Loeper, who has been elected to the chair of clinical medicine.

BERLIN

(From Our Regular Correspondent)

July 1, 1935

Secondary Effects Following the Use of Amidopyrine

In a recent address before the Berlin Medical Society Professor Dennig spoke on the secondary effects following the use of amidopyrine and related drugs, a subject much discussed in various countries, especially in connection with the appearance of agranulocytosis following the ingestion of amidopyrine. Usually it is a question of relatively harmless idiosyncrasies, but a form of idiosyncrasy that leads to agranulocytosis may take a fatal course. Hence, in manifestations of angina under which picture an agranulocytosis first presents itself clinically, patients should be warned against the use of amidopyrine and related drugs likewise in mild disorders in which medicines are not needed. On the other hand, Dennig and other clinicians have not observed these injuries following the application of large doses of amidopyrine (even of several grams) in articular rheumatism.

Prof Werner Schultz, who was one of the first to describe the disease termed "agranulocytosis" stated during the discussion that he had not observed such connections. The incidence of agranulocytosis is far from uniform. In Denmark it appears to be common. In any event, in cases of agranulocytosis all preparations should be omitted that contain amidopyrine in any

form since they effect a marked exacerbation of the disease. Professor Schittenhelm pointed out that a diminution of leukocytes, such as occurs in agranulocytosis, may be produced not only by amidopyrine but also by salicylic acid, cinchophen and other substances.

Meeting of Microbiologists

The May session of the Deutsche Vereinigung für Mikrobiologie opened with commemorative exercises for Robert Koch. The first topic, "Diphtheria," was introduced by Schlossberger of the federal bureau of health, who discussed the new division of diphtheria bacilli according to definite cultural characteristics, into the three types "gravis," "mitis" and "intermedius," a division which appears to be acceptable, whereas an immunologic division of the various stocks is not so useful. Gundel of Berlin emphasized the importance of the three types in epidemiology and termed the distribution of diphtheria bacilli as "practically ubiquitous." In diphtheria outbreaks one may speak of a quantitatively graduated contamination of one's environment. What causes diphtheria to appear and to disappear is not perfectly understood.

Kleinschmidt emphasized the great difference in the aspects of the disease and spoke of a pathomorphosis, since now there is much more pharyngeal than laryngeal diphtheria, which is just the opposite of formerly. Toxic diphtheria is for a time rare and then for a time frequent. In specific therapy one must bear in mind that normal horse serum always contains a few units of antitoxin. Death may intervene, however, in spite of maximal serum doses of from 100,000 to 500,000 units. But every physician is morally obligated to use the serum. Intravenous injections of serum are best given in a clinic. Clauberg brought out that in diphtheria one must count on a third of the population as bacillus carriers, it is useless therefore to isolate those who happen to come down with the disease.

Several unofficial papers were presented. According to Uhlenhuth and Zimmermann, Weil's disease may be transmitted even by the bite of tame rats. This disease may resemble meningitis without icterus. Schöffner of Amsterdam reported that among 105 cases in the Netherlands seventeen were fatal. The therapeutic serum gave favorable results. Bathing in open waters is the most frequent source of the infection, which was confirmed by observations in the navy.

In the determination of the blood groups, Laubenheimer of Frankfurt advised great caution particularly in the determination of the M and N factors in court trials in which the paternity of a child is involved, since the courts are coming to accept the testimony of experts in this field.

Veneral Disease in Thuringia

According to the federal census of venereal diseases for 1934, there are in Germany every year 346 new infections with venereal disease to each 10,000 inhabitants. In Thuringia there are 32.2 new cases. Dr. W. Schultze stated in an address before the Medical Society of Jena. In the reich, from 1927 to 1934, the number of new infections dropped from 585 to 346 per 10,000 of population. In Thuringia, during the same period, there was a decline from 399 to 323. The most common venereal disease is gonorrhea (78 per cent), while soft chancre with only 0.5 per cent plays but a small part. Congenital syphilis has decreased one half. In Thuringia, which comprises a part of "central Germany," one has to count on 1,400 new cases of syphilis and 4,200 new cases of gonorrhea each year. The principal center for the detection and registration of venereal patients is a consultation center at the Landesversicherungsanstalt in Weimar, the capital of Thuringia. A working merger with the Krankenkassen has been established, so that the cost of treating infectious patients is regulated on a large scale. In cities in which brothels still exist the morbidity figures are higher than elsewhere. The cost in

caring for prostitutes who were ill for some individuals reached as high as 2,750 marks (\$1,100) in a single year. In October 1934 a special department for asocial female venereal patients was established, which is under the control of the University Dermatologic Clinic in Jena. As asocial are designated such persons as have promiscuous intercourse and thus expose themselves to infection, venereal patients who have recurrences continually, and patients who refuse to be classed as members of any recognized working body. To this group belong all venereal patients who manifest indolent or criminal tendencies. In this special department patients become accustomed to a regular mode of living, they are obliged to work and have a definite daily schedule for labor and rest. A similar department for asocial male venereal patients is to be created. If these patients show that they have actually changed their attitude toward life and desire to secure permanent work, a carefully chosen opening is provided in which they must voluntarily submit to a special form of supervision. Patients with mental defects are placed in corresponding institutions. Asocial patients who show no signs of regeneration or social improvement are retained in "closed" institutions.

Malignant Tumors of the Mouth

Professor Lindemann, who is the director of the large West German clinic in Düsseldorf, where the treatment of diseases of the jaws is a specialty, has made a careful study of more than 200 cases of carcinoma and sarcoma. The results of a radical surgical treatment of these malignant tumors have improved greatly, chiefly owing to a better knowledge of the early symptoms and to refinements in the surgical accomplishments as regards radical excisions of tumors, and because of the great advances in plastic surgery as applied to large defects of the face. The ability to avoid postoperative disturbances through the progress in local and regional anesthesia has been a great advantage. According to the experiences of Lindemann, an irradiation effects frequently a reduction in the size of such a tumor, so that a radical excision becomes possible. Another important question is as to whether an ulcerated tumor or a tumor that has led to regional metastases should be irradiated. Professor Schreus stated that the radiologic treatment will vary widely, depending on the site and the degree of extension to the deep-lying tissues, for which adequate methods have been worked out. In accordance with the special indications, the specialist will apply fractionated irradiation with short intervals, contact treatment with application of radium, radium needle treatment, and irradiation by the Coutard method in the form of percutaneous therapy. Schreus has an increasing preference for radium treatment within the tumor, particularly in glandular metastases. In suitable cases the radial application of radium needles to the tumor is recommended. Some patients who were irradiated several years ago are still alive. If recurrences are to take place after unsuccessful irradiations, they usually appear promptly. From the experiences of Schreus, irradiation appears to be the preferred method in carcinoma of the upper jaw, also in lingual and in pharyngeal tumors.

Sixtieth Birthday of Professor Sauerbruch

Prof. Ferdinand Sauerbruch, the directing surgeon of the Berlin University Surgical Clinic, celebrated his sixtieth birthday, July 3. In the beginning of his career he served as assistant to Langerhans. In Breslau, under Mikulicz, his reputation became established. After serving in the university clinics of Greifswald and Marburg, he was offered in 1910 a chair in the University of Zurich. In 1918 he accepted a call to the University of Munich, and in 1928 to the University of Berlin. His reputation was now great enough to take a position alongside August Bier. The subpressure procedure introduced by him makes it possible to open the thoracic cavity without collapse

of the lung, which is under negative pressure. This procedure enables the operator to undertake extensive operations on the lungs, which denotes a distinct advance. Since then Sauerbruch has worked out this procedure more in detail, introducing many improvements. During the World War he invented a movable prosthesis for persons with amputated limbs. The idea was to utilize the movable muscles of the stump for the control of the prosthesis. Sauerbruch has carried on researches on surgery of the pericardium, the heart and the large blood vessels of the thorax, and on thoracoplasty. His researches on diet in tuberculosis are well known. He is the editor or collaborator of some of the most important textbooks on surgery. As a teacher he charms by his enthusiastic presentation. His lectures, which he often delivers in foreign countries, are noteworthy presentations of surgical doctrine.

Supervision of Adolescents in Industry

Dr. Langelez, "inspector general" of the Service médical du travail, has an article in the *Revue du travail* on the sanitary supervision of adolescents. In 1920 the work begun by Dr. Glibert in this field was sanctioned by a royal decree. Dr. Langelez, who for a number of years has been in a position to observe how the prescribed measures are applied and what results are secured, gives a summary of his observations.

The sanitary supervision of adolescents in industry, as organized in Belgium, is designed to render to the adolescent man power in our industrial plants constant service. In guiding youth's first step in the industrial life, in aiding young persons in the choice of a means of livelihood and in their adaptation to the trades, in supervising their first years of industrial activity, in watching over the less alert and in discovering at the start disturbances of health, this organization deserves a special place among the movements whose avowed task is the protection of workers. As Dr. Glibert said one day, "What finer service can physicians render than to watch over the normal development and the physical growth of the future generation of producers of wealth?"

To say that the organization as it exists is perfect would be an error. But does it reach all those that it is designed to aid, namely, boys and girls from 14 to 18 years of age in all industries except that of the home and the exploitation of agricultural work? One may reply that the organization functions efficiently in the major industries, in the middle-sized industries, and in a large portion of the minor industries. Its principles are the most difficult to apply in the minor industries in which there are only one or two apprentices, but in the trades presenting appreciable dangers the health of adolescents is periodically observed.

"Are the medical examinations made with sufficient care?" "Is there, in the organization of this service, nothing mechanical in the administration and in the paper work?" In reply to these questions, it should be said that sanitary supervision is as all other human endeavors. The better the physician the better the work is done that is entrusted to him, whether it is a question of industrial medicine, inspection of schools, consultations for nurslings or antituberculosis dispensaries. There are, however, certain organizations that are practically perfect, in which the physicians perform their tasks with the zeal and conscience of an apostle. Men of their caliber understand that the medicine of today demands more than formulas for treatment and prescriptions of drugs. The physician of the future must not devote his entire attention to therapeutics but must take on new activities born of modern hygiene and of preventive medicine. The protection of childhood, the medical surveillance of school children, and the sanitary supervision of adolescents in industry are movements the social value of which is apparent.

to every one, but their value in an individual case depends on the type of physician that administers them

In one sense, the sanitary supervision of adolescents is only a continuation of the guardianship to which school children in Belgium are subject. The mode of functioning of the service may be summarized as follows: examination one month after the new work is begun, an annual general survey of adolescents with supplementary examinations after one month, three months or six months. The examinations are given either by the medical inspectors of the ministry of health or by physicians selected by the industrial heads.

Diphtheria Carriers in Children's Colonies

In the children's colonies it has become customary to examine the whole group to discover carriers of diphtheria bacilli. In the Dongelberg colony during 1931 and 1932, Nelis searched for the Loeffler bacillus in 1,779 children. He discovered it in thirty-five cases, or 2 per cent. In the Wesembeek colony, twenty-four germ carriers were discovered in a group of 548 children (4.4 per cent), in the Cortil colony, five in a group of 175 (3 per cent) at the Jaspar Institute, six in a group of 109, at the Ecole d'Evere, one in a group of ninety-one, or seventy-one carriers of diphtheria bacilli (2.6 per cent) in the 2,702 children examined.

While the elimination of carriers improves the sanitary situation, one must not count too much on this method for between the arrival of a new contingent and the time when the results of the bacteriologic examinations become known, several days elapse, during which the carriers disseminate bacilli. Furthermore, in some subjects the presence of pathogenic organisms in the throat is intermittent. Then again, isolation of carriers is not practicable in these colonies.

The measure that is most effective is vaccination with anatoxin. Nelis considered that in the colonies that receive the whole contingent on a fixed date it is preferable to vaccinate all the children at the start, without applying first the Schick test to eliminate those with a negative reaction. In the colonies that receive children continually, one should either vaccinate every six months the children with a positive Schick reaction or vaccinate the children at once as they arrive.

Should the children be vaccinated in case of an epidemic? It is advisable to administer first an injection of anatoxin, to follow it up immediately with an injection of preventive serum, and later to return to vaccination.

Maritime Medical Aid

The story of the organization of maritime medical aid by means of the radio as a result of the initiative taken in Belgium by Dr. Bernard is well known. Dr. Bernard, in collaboration with Dr. Haack, has just published an interesting monograph on the subject. The International Radiomedical Service with its ninety-three equipped stations is having a world-wide development. One of its principal aids, the Manuel medical international, has been prepared and is expected to appear soon. The authors feel justified in appealing to the nations that have not yet established coastal radiomedical service. This applies to the vast expanses of the South Atlantic, the Indian Ocean and a part of the Pacific.

Likewise medicine chests should be standardized as that would contribute greatly to the efficacy of the service. Until such standardization can be effected all the radiomedical stations should be supplied with a pamphlet giving the composition of the medicine chests of each country.

The program of the service should include also study courses leading up to examinations for marine officer and also elementary courses theoretical and practical in radio medicine.

Great importance attaches to the creation of a central organization for the establishing of criteria to control radiomedical diagnoses.

BUDAPEST

(From Our Regular Correspondent)

July 3, 1935

The Eleventh National Medical Congress

The attendance at the eleventh National Medical Congress, held in May at the picturesque resort of Lake Balaton, exceeded all previous records. The program was unusually instructive.

INSUFFICIENCY OF THE CORONARY CIRCULATION

Prof. Arthur Hasenfeld said that insufficiency of the coronary circulation is in the foreground among investigators of cardiac disease. He emphasized that the increase in heart lesions is due to disorders of the coronary arteries. These can be prevented and in many instances cured. He strongly condemns attempts to cure angina pectoris by surgical operations. He never had a patient with angina operated on, nor will he ever operate for this condition. He is of the opinion that such methods are dangerous and unjustified. The preservation of the coronary arteries is one of the most important requirements for longevity. Sparing the heart means at the same time sparing the coronary arteries and is best insured by adequate rest after work, annual vacations of a fortnight or two and reasonable bathing, if possible in water containing carbon dioxide.

NEW DOCTRINES IN THE STUDY OF TUBERCULOSIS

Prof. Johann Angyan expressed the opinion that the sanatorium system of treatment of tuberculosis gave unsatisfactory results. In the postwar years valuable data were accumulated mainly as the result of the development of artificial pneumothorax and of serial roentgenograms. Tuberculosis affects the whole duration of life in cycles. The character of the disease varies in different periods of life. This cyclic course is attributable to the fact that people are usually infected prior to their tenth year of life, consequently the campaign against tuberculosis in infancy is of the greatest importance. In this field much can be expected from the social service system. But simply making the campaign one of housing, clothing and feeding leads to dependence on the daily trend of politics, and the campaign against tuberculosis should be free from politics. The chief endeavor of the campaign should be to remove the children from the sphere of grown-ups who are infected. Therefore the work of asylums should be directed toward serving these child groups, placing children in healthy homes. In the children's sanatoriums, the number of which is relatively small in place of convalescent and holiday measures tuberculous children should be cured.

THE PREVENTION OF CANCER

Endre Kubany stated that the strides made in the last decade have definitely demolished the false dogma that no scientific knowledge exists regarding the etiology of cancer. In the origin of cancer there are two factors to be reckoned with. One is the local stimulus which incites the cells to propagation, in most cases without any cause, the other is the individual tendency whereby the cell propagation caused by external stimuli passes into a cancerous growth. The individual predisposition is inheritable. The cancer of workers dealing with aniline, arsenic or tar corroborates the statement that already there are known causative agents. The therapeutic achievements of the last three decades established that cancer in its initial stage is curable. Hungary and chiefly its capital Budapest, despite its financial difficulties, will shortly extend all branches of research to achieve the utmost in this field. The Swedish, English, American, French and Belgian anticancer movements show that curing cancer is, in a great measure, a question of financing and organization. While discovery of the etiology of cancer is a scientific question, the prevention of cancer is a problem of organization.

ITALY

June 30, 1935

Chronic Appendicitis

Under the chairmanship of Professor Donati of the University of Milan, the Società medicochirurgica lombarda held a session devoted entirely to chronic appendicitis. According to Ferrata, chronic appendicitis from the start follows its clinical course uninfluenced by acute, subacute or recurrent appendicitis. He regards chronic appendicitis as an inflammatory disturbance of Peyer's patches and the enclosed follicles. Constitutional factors play a large part in its causation. Ferrata expressed the view that medical treatment is not effective and that the problem is essentially surgical.

Maioocchi gave statistical data on 1,600 appendectomies performed in the Ospedale Maggiore in Milan. He believes in the existence of chronic appendicitis from the start, but he regards it as a rare type (about 6 per cent). Timely intervention avoids the necessity of making changes in the other abdominal organs, particularly the stomach and the gallbladder.

Perussia, radiologist, discussed the value of roentgenologic symptoms of chronic appendicitis, none of which are pathognomonic.

Castiglione demonstrated the existence of those forms of appendicular disease which sometimes are induced by changes in the elastic and the nervous tissues. Clinically important are the disturbances that may simulate changes in the urinary apparatus and make one suspect the existence of an appendiculo-urinary reflex. It is necessary, he emphasized, to distinguish carefully the syndrome of appendicular disease from numerous other syndromes that might lead to useless appendectomies.

Solaro, in 1,300 operations for appendicitis in fourteen years, found chronic appendicitis in 40 per cent. Only in 21 per cent of these were the lesions confined to the appendix so that appendectomy constituted an adequate intervention. In the majority of cases, the lesions of the appendix were associated with symptoms of perivisceritis of the right side, hence the need of adhering to ample incisions sufficient to explore not only the appendix but also all the organs of the right half of the abdomen.

Zaccardi and Mucchi discussed the diagnostic difficulties that arise in connection with chronic inflammatory tumors of appendicular origin, especially in differential diagnosis as against a neoplasm of the ascending cecum.

Ettorre considered the diarrheic type of chronic appendicitis—a clinical form little known, which differs from the ordinary picture in that attacks of diarrhea alternate with periods of regular functioning, without any evident symptoms involving the appendix.

Analgesia and Anesthesia

A new society, the Società italiana di chirurgia e anestesia, has been founded in Rome. At the first session Prof. Roberto Alessandri, clinical surgeon, spoke on the more extensive use of local anesthesia, together with the preparation of patients by means of basal anesthesia. Local anesthesia has great merit and constitutes an ideal method, owing to the absence of harmful effects on the organism. Its greatest disadvantage is the incomplete character of the analgesia. The basal anesthesia strengthens its action and makes the patient more sensitive to the drug used locally. Scopolamine dilaudid (a combination of hydromorphone and scopolamine) is an optimal substance for basal anesthesia. Alessandri has used this preparation in a large number of cases for grave interventions, mostly cases of gastric surgery, such as resection for ulcer and cancer, and thoracoplastic surgery. He thinks that the custom of combining basal anesthesia with local anesthesia will be more widely adopted by surgeons.

Professor Testoni spoke on his direct experiments to determine the mechanism of vomiting due to chloroform. He excludes the gastric mucosa as the starting point of the vomiting reflex. Chloroform is not eliminated through the stomach, as occurs in the case of other indirect emetics, and Testoni holds that the anesthetic acts principally by exciting directly the bulbar center that controls vomiting. He does not, however, deny that vomiting due to chloroform may be also of reflex origin, in that case the starting point of the reflexes would have its seat not in the gastric mucosa but in other reflexogenic areas, the most important of which are the heart and the sinus caroticus.

Blood Transfusion

The public health service has brought to the attention of the prefects a decree of the minister of the interior outlining the norms pertaining to blood transfusion and to the use of human blood serum. The preparation for curative and prophylactic purposes of serums derived from persons convalescent (or cured) from poliomyelitis, measles, scarlet fever or other infective diseases will be subject to surveillance according to the norms established for serums and vaccines of animal origin. The collection of human blood and the preparation of serum may be carried out only at special collection centers or at institutes authorized by the minister of the interior. Blood donors for the preparation of serums must be at least 10 years old, of a sound constitutional type, and free from infectious diseases in general, particularly syphilis, tuberculosis and malaria.

Blood donors for blood transfusion must be found suitable as a result of rigorous clinical and laboratory examinations and must belong to a blood group compatible with that of the recipient.

The bureau of health in each commune shall keep a list of the voluntary and professional blood donors. They shall be provided with a special record card showing the blood group to which they belong, and they must subject themselves to a control examination at least every three months.

A physician who intends to give a blood transfusion must prefer his request for a donor to the communal health officer. In case of urgent need he may make use of a donor who appears suitable even though not enrolled in the communal register.

The formation of an association of blood donors, under the supervision of the sanitary authorities, is authorized.

Marriages

BRUCE NEWCOMER WOLFF, Gettysburg, Pa. to Miss Dorothy Burg Seiple, at Boiling Springs, Pa., June 8.

HARRY EARL PFEIFFER to Miss Edlee May Robinson, both of Cedar Rapids, Iowa, in Chicago, June 29.

GEORGE W. SIPPOLA, Detroit, to Miss Gladys H. H. Niemi of Riverside, Ont., Canada, June 6.

JOHN W. HOUR, Cleveland, to Miss Mary Hammond O'Brien of New Haven, Conn., July 27.

S. MILES BOUTON JR., Sykesville, Md., to Miss Martha Turnquist of Chicago, July 24.

HENRY F. CARMAN JR., Butte, Mont., to Miss Margaret E. Smith of Chicago, June 25.

JOHN ROBERT ANDREWS, Cleveland, to Miss Anne Cosgrove, at Philadelphia, June 15.

ROBERT B. WALKER to Miss Helen Grace Young, both of Philadelphia, June 8.

HAROLD O. GARDNER, Waterloo, Iowa, to Miss Vera Bittle of Lisbon, July 9.

LESTER L. LONG to Miss Esther May Payne, both of Seattle, June 29.

HARRY MEYER to Miss Marion Hirsch, both of New Orleans, June 11.

Deaths

Edwin Raymond Le Count * professor of pathology in Rush Medical College since 1892, died in Chicago at the Presbyterian Hospital August 23 of coronary thrombosis. Dr Le Count was born in Wisconsin, April 1, 1868. After graduation from Carroll College he attended Rush Medical College and received his M.D. degree in 1892. Thereafter he pursued graduate studies in Johns Hopkins Hospital in 1893 and 1894, in the Pasteur Institute in Paris in 1896 and in Berlin in 1905. He served at various times as attending pathologist in the Cook County, Presbyterian and St. Luke's hospitals and also at St. Elizabeth's and St. Anthony's hospitals. He was a member and once president of the American Association of Pathologists and Bacteriologists and was a president of the Association for Cancer Research. He was also a member of

the American Association for the Advancement of Science and of the Society of American Bacteriologists. In the American Medical Association he served as a member of the House of Delegates in 1903 and as chairman of the Section on Pathology and Physiology from 1920 to 1921. He was the author of numerous contributions to the literature of his specialty, particularly on such subjects as the relative frequency of the various forms of coma, automobile injuries, skull fractures, air and fat embolism and blastomycosis. In his long service as pathologist to so many institutions he performed approximately 20,000 postmortem examinations. He was noted particularly for his training of young men in pathology, and many of the younger leaders in this field today were associated at various times with him. At the time of his death he had completed postmortem records extending over a period of twenty-five years, completely indexed and annotated, and presented these as a permanent contribution to the library of Rush Medical College.

EDWIN RAYMOND LE COUNT
1868-1935

Otto L. Schmidt * an educator, a medical historian of considerable note, a sportsman, and a beloved family physician, died in Chicago, August 20, of carcinoma of the prostate with metastasis, aged 72. Dr Schmidt was the son of a physician, Dr E. S. Schmidt. He received his M.D. degree from the Chicago Medical College in 1883 and after postgraduate work abroad took up the practice of medicine in Chicago. He was a consultant to the Alexian Brothers Hospital and a member of the staff of other Chicago institutions. From 1915 to 1919 he served as chairman of the Illinois Centennial Commission. He was a past president of the Institute of Medicine in Chicago, the Illinois Historical Society, the Illinois Historical Library and the Chicago Historical Society. He was also president of the Inland Lake Yachting Association. Dr Schmidt served as a member of the Board of Education of the City of Chicago during the Dever administration and took a prominent part in maintaining the ideals of education during the attacks on Superintendent of Schools William McAndrew. He was decorated by the Austrian government in 1923 for postwar relief work. His two daughters are wives of physicians.

George Gregory Carroll * Rochester, N. Y. University of Pennsylvania Department of Medicine, Philadelphia 1900 member of the American Academy of Ophthalmology and Otolaryngology, the American Laryngological Rhinological and Otolological Society and the American Bronchoscopic Society, fellow of the American College of Surgeons, aged 61, on the staffs of the Genesee Hospital, Monroe County Hospital, St. Mary's Hospital, St. Mary's Boys Orphan Asylum and the Park Avenue Hospital, where he died, July 23, of heart disease and diabetes mellitus.

William L. Callaway, Chicago, Barnes Medical College, St. Louis, 1897, member of the Illinois State Medical Society, formerly professor of clinical medicine, Chicago College of Medicine and Surgery, Bennett Medical College and Loyola University School of Medicine, on the staff of the West Side Hospital, aged 65, died, July 24, of angina pectoris.

Martha Jane Bledsoe, Chickasha, Okla., Keokuk Medical College, College of Physicians and Surgeons, Keokuk, Iowa, 1906, member of the Oklahoma State Medical Association, past president and secretary of the Grady County Medical Society, formerly on the staff of the Chickasha Hospital, aged 72, died, July 3, of chronic myocarditis.

Henry Bierman * Bloomsburg, Pa., Hahnemann Medical College and Hospital of Philadelphia, 1888, past president of the Columbia County Medical Society, served during the World War, on the staff of the Bloomsburg Hospital, aged 70, died, July 22, in the Geisinger Hospital, Danville, of carcinoma of the sigmoid with metastasis to the liver.

William Mack Elliott, Lancaster, Ky., Kentucky School of Medicine, Louisville, 1896, member of the Kentucky State Medical Association, city judge, formerly superintendent of the Central State Hospital, Lakeland and the Western State Hospital, Hopkinsville, aged 61, died, June 29, of diabetes mellitus and cerebral hemorrhage.

George Parker Holden, Yonkers, N. Y., New York Homeopathic Medical College and Hospital, 1894, member of the Medical Society of the State of New York, fellow of the American College of Surgeons, aged 65, on the staff of the Yonkers General Hospital, where he died, July 15, of cerebral hemorrhage.

Luther Samuel Hirt, Brazil, Ind., University and Bellevue Hospital Medical College, New York, 1899, member of the Indiana State Medical Association, past president of the Clay County Medical Society, on the staff of the Clay County Hospital, aged 60, died, July 31, of carcinoma of the lung.

Oscar Raoul Talon L'Esperance * Boston, Boston University School of Medicine, 1909, member of the American Urological Association, assistant urologist to the Massachusetts General Hospital, 1925-1928, aged 56, died, July 15, at his home in Centerville, of acute dilatation of the heart.

Andrew Crozier Cameron, Birmingham, Ala., University of Pennsylvania Department of Medicine, Philadelphia, 1904, member of the Medical Association of the State of Alabama, on the staff of St. Vincent's Hospital, aged 55, was found dead in bed, June 10, of heart disease.

John Loy Arnold, Harrisburg, Pa., Jefferson Medical College of Philadelphia, 1911, member of the Medical Society of the State of Pennsylvania, served during the World War, aged 47, on the staff of the Harrisburg Hospital, where he died, July 26, of coronary thrombosis.

Andrew J. Brislen * Chicago, Northwestern University Medical School, Chicago, 1895, at one time instructor in anatomy at his alma mater, on the staff of the Woodlawn Hospital, aged 61, died, July 23, in the Albert Merritt Billings Hospital, of cerebral thrombosis.

William Jones Thomas * Ravenna, Ohio, Western Reserve University Medical Department, Cleveland, 1898, past president of the Portage County Medical Society, aged 65, on the staff of the Robinson Memorial Hospital, where he died, June 24, of Banti's disease.

Anthony Joseph Caffrey * Milwaukee, Baltimore Medical College, 1898, formerly assistant professor of medicine, Marquette University School of Medicine, on the staffs of St. Joseph's Hospital and St. Anthony's Hospital, aged 64, died, July 11, of cerebral hemorrhage.

George A. Macdiarmid * New Orleans, Victoria University Medical Department, Coburg, Ont., Canada, 1886, formerly bank president, aged 71, died, June 29, in the Baptist Hospital of a fracture of the neck of the femur and traumatic ileus, following a fall.

Perry Engle, Newton, Iowa, University of Michigan Department of Medicine and Surgery, Ann Arbor, 1871, member of the Iowa State Medical Society, formerly member of the state legislature, aged 91, died, June 29, of Ludwig's angina.

Samuel Thomas Blades * Salina, Kan., University Medical College of Kansas City, Mo., 1903, past president of the Saline County Medical Society, on the staff of St. John's Hospital, aged 60, died, May 6, of nephritis and hypertension.

Frank M. Barden, Hamilton, Ohio, Medical College of Ohio, Cincinnati, 1890, past president of the Butler County Medical Society, on the staffs of the Fort Hamilton and Mercy hospitals, aged 70, died, July 25, of carcinoma of the lung.

Julian Augustine Chase * Pawtucket, R. I., Harvard University Medical School, Boston, 1872, past president of the Rhode Island Medical Society, on the staff of the Memorial Hospital, aged 86, died August 12, of chronic myocarditis.

Emanuel de Marnay Baruch * New York, College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1889, aged 64, died, July 1, at his summer home in Valhalla, N. Y., of cerebral hemorrhage.

Richard Franklin Hinman * Chicago, Bennett Medical College Chicago, 1912, on the staffs of the Garfield Park Hospital and the Frances Willard Hospital, aged 60, died, July 20, of brain tumor and arteriosclerosis.

Camillus I. Holt, Olton, Texas, Jefferson Medical College of Philadelphia, 1885, member of the State Medical Association of Texas, county health officer, aged 72, died, May 7, in a sanatorium at Plainview, of pneumonia.

William Alonzo Moon, Bellbuckle, Tenn., University of Tennessee Medical Department, Nashville, 1894, aged 75, died, July 1, in the Protestant Hospital, Nashville, as the result of fracture of the hip, received in a fall.

Joseph R. Beckley, Lebanon, Pa., University of Pennsylvania Department of Medicine, Philadelphia, 1885, member of the Medical Society of the state of Pennsylvania, aged 75, died July 3, of coronary thrombosis.

Samuel Bennehoff, Franklin, Pa., Cleveland College of Physicians and Surgeons, Medical Department of the University of Wooster, 1873, aged 86, died, July 23, of cerebral hemorrhage and pneumonia.

Eugene Thompson, East St. Louis, Ill., Missouri Medical College, St. Louis, 1890, member of the Illinois State Medical Society, served during the World War, aged 70, died, June 19, of cerebral hemorrhage.

George Russell Thompson, Luzerne, N. Y., Eclectic Medical College of the City of New York, 1896, health officer and school physician, aged 60, died, May 14, of chronic nephritis and endocarditis.

Frank Harlan Frederick, Pittsburgh, Western Pennsylvania Medical College, Pittsburgh, 1897, member of the Medical Society of the State of Pennsylvania, aged 65, died, June 21, of coronary occlusion.

John Locke Churchill, Halifax, N. S. Canada, McGill University Faculty of Medicine, Montreal, Que., 1896, superintendent of the Nova Scotia Hospital, aged 63, was found dead in bed, June 22.

Russell William Kapp * San Jose, Calif., Hahnemann Medical College and Hospital of Philadelphia, 1925, aged 35, died, May 5, of rupture of the right ventricle and fatty degeneration of the heart.

William Daniel Webb, St. Joseph, Mo., Ensworth Medical College, St. Joseph, 1909, member of the Missouri State Medical Association, aged 59, died, May 8, of chronic rheumatic heart disease.

Clarence S. Bates, Lumberport, W. Va., Baltimore University School of Medicine, 1904, member of the West Virginia State Medical Association, aged 60, died, June 9, of coronary occlusion.

Irwin Carson Carlisle, West Dover, Ohio, University of Wooster Medical Department, Cleveland, 1875, member of the West Virginia State Medical Association, aged 82, died, June 22, of heart disease.

Charles Francis McCarthy, Point Loma, Calif., University of California Medical Department, San Francisco, 1893, aged 68, died, June 27, of duodenal ulcer, arteriosclerosis and coronary sclerosis.

George McKenzie, Concord, Calif., University of Toronto (Ont.) Faculty of Medicine, 1891, aged 72, died, May 17, in the Merritt Hospital, Oakland, of myocarditis, chronic nephritis and prostatitis.

John A. Richardson * Seymour, Texas, Memphis (Tenn.) Hospital Medical College, 1892, past president of the Baylor County Medical Society, aged 67, died, May 29, of cerebral thrombosis.

Clark Samuel Long * Lansdale, Pa., University of Maryland School of Medicine, Baltimore, 1916, for many years member of the school board, aged 47, died, July 17, of coronary thrombosis.

Lacy Newton Conolly * Camden, N. J., Jefferson Medical College of Philadelphia, 1919, aged 43, on the staff of the Cooper Hospital, where he died, July 9, of essential hypertension.

Albert E. Mieding * Milwaukee, Milwaukee Medical College, 1906, aged 69, died, July 23, at Three Lakes, Wis., of a fractured neck, received when he dived into shallow water.

Harvey Lee Tadlock, Holt, Mo., Ensworth Medical College, St. Joseph, 1903, aged 65, died, June 13, of undulant fever, nephritis, angina pectoris, arteriosclerosis and hypertension.

Lewis Munthe Berg * Chicago, Tulane University of Louisiana Medical Department, New Orleans, 1890, aged 79, died, July 31, of chronic myocarditis and arteriosclerosis.

Robert Lewis Hill Jr., Santa Paula, Calif., Hahnemann Hospital College of San Francisco, 1895, aged 63, died, May 30, of chronic nephritis, arteriosclerosis and myocarditis.

Joseph Sesansky * Buffalo, Long Island College Hospital, Brooklyn, 1915, on the staff of the Memorial Hospital, aged 40, died, July 15, in the Buffalo General Hospital.

Raymond O. Hathaway, Monroe, Mich., Detroit College of Medicine and Surgery, 1913, on the staff of the Monroe Hospital, aged 46, died, July 15, of erysipelas.

Darius Burtch, Watsonville, Calif., College of Physicians and Surgeons, Keokuk, Iowa, 1884, aged 73, died, June 19, of valvular heart disease and chronic myocarditis.

William H. Stoakes, Albion, Neb., State University of Iowa College of Homeopathic Medicine, Iowa City, 1901, aged 80, died, June 28, of senile dementia.

George Robert Fellows, Seabrook, N. H., Druidic University of Maine, Lewiston, 1886, aged 86, died, June 20, at Lake Mary, Fla., of cerebral hemorrhage.

Joseph Borak * Brooklyn, University and Bellevue Hospital Medical College, New York, 1925, aged 35, died, July 20, when he was struck by lightning.

Jacob Harper Bain * New Concord, Ohio, Ohio Medical University, Columbus, 1902, aged 58, died, June 12, of coronary thrombosis and arteriosclerosis.

George Ray Hill, Charter Oak, Iowa, Homeopathic Medical College of Missouri, St. Louis, 1904, aged 58, died, May 23, of streptococcal pneumonia.

Winfield Murray Bishop, Baltimore, Temple University School of Medicine, Philadelphia, 1923, aged 41, died, June 17, of myocardial insufficiency.

George Duling Carter, Anthony, N. M., Barnes Medical College, St. Louis, 1898, aged 61, died, July 4, of angina pectoris and arteriosclerosis.

Alphonse Leon Beardslee, Chicago, State University of Iowa College of Medicine, Iowa City, 1918, aged 41, died, May 5, of lobar pneumonia.

William Warnock Bailey * Davenport, Iowa, Marion Sims College of Medicine, St. Louis, 1897, aged 69, died, August 6, of myocarditis.

Frank Monroe Cain, Pittsburgh, Jefferson Medical College of Philadelphia, 1889, aged 73, died, June 23, of coronary occlusion and arteriosclerosis.

James Irvin Allen, Oshkosh, Neb., College of Physicians and Surgeons, Keokuk, Iowa, 1890, aged 72, died, July 4, of perforated gastric ulcer.

Peter Phelps Collins, Denver, Chicago Homeopathic Medical College, 1895, aged 62, died, June 19, in St. Luke's Hospital, of pneumonia.

Fred Flanagan Gremore, Saranac Lake, N. Y., Albany (N. Y.) Medical College, 1905, aged 53, died, May 7, of Huntington's chorea.

John Logue, Red Rock, N. Y., University of the City of New York Medical Department, 1889, aged 70, died, May 16, of chronic nephritis.

Benson T. Allen, Minneapolis, Eclectic Medical Institute, Cincinnati, 1885, aged 81, died, May 19, of arteriosclerosis and hypertension.

Charles P. Harwood, Havana, Cuba, University of Louisville (Ky.) Medical Department, 1894, aged 62, died, July 6, of tuberculosis.

James Ernest Bond, Toronto, Ont., Canada, University of Toronto Faculty of Medicine, 1914, aged 46, died, June 12, of pneumonia.

John Horace Burnett, Fostoria, Ohio, Eclectic Medical Institute, Cincinnati, 1881, aged 79, died, June 26, of arteriosclerosis.

John M. Sherman, Long Beach, Calif., College of Physicians and Surgeons, Keokuk, Iowa, 1880, aged 84, died, June 20.

James Burris Mahony, New York, Rush Medical College, Chicago, 1901, aged 58, died, June 24, of heart disease.

Andrew Goetz Ludwig, St. Catharines, Ont., Canada, Trinity Medical College, Toronto, 1897, aged 62, died, May 25.

J. L. Allison, Rochester, Ind. (licensed in Indiana in 1903), aged 75, died, June 17, in Brookston, of angina pectoris.

Bureau of Investigation

MISBRANDED "PATENT MEDICINES"

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the United States
Department of Agriculture

[EDITORIAL NOTE The abstracts that follow are given in the briefest possible form (1) the name of the product, (2) the name of the manufacturer, shipper or consigner, (3) the composition, (4) the type of nostrum, (5) the reason for the charge of misbranding and (6) the date of issuance of the Notice of Judgment—which may be considerably later than the date of the seizure of the product.]

Manno—Scientific Mfg Co, Scranton Pa Composition Plant drug extracts including a laxative drug glycerin small amounts of baking soda and magnesium carbonate, and a trace of ipecac alkaloids with alcohol and water For indigestion ptomaine poisoning etc. Fraudulent therapeutic claims—[N J 22304 November 1934]

Paten—Composition Essentially a lead soap rosin and camphor For all kinds of sores (except cancers) Misbranded because statement Guaranteed under the Food and Drugs Act June 30 1906 gave the mistaken impression that the stuff had been examined and approved by the government whereas it had not fraudulent therapeutic claims—[N J 22306 November 1934]

H Heehles Velocite Earth—Mene L de Freese, La Mesa Calif Composition Finely powdered iron calcium and aluminum silicate For catarrh diphtheria whooping cough diarrhea headache insomnia skin disorders etc. Fraudulent therapeutic claims—[N J 22307 November 1934]

MI Cro Line Bladder and Kidney Remedy—Microline Medicine Co Dallas Texas Composition Essentially volatile oils including eucalyptus a fatty oil and benzoic acid Fraudulent therapeutic claims—[N J 22308 November 1934]

Eucalloe Tonic Compound—Eucaline Medicine Co Dallas Texas Composition Essentially cinchona alkaloids (quinidine and cinchonidine) acetanilid (27 grains per fluid ounce) with oil of peppermint alcohol sugar and water For la grippe stomach disorders etc. Fraudulent therapeutic claims—[N J 22308 November 1934]

Admirins—Microline Medicine Co Dallas Texas Composition Essentially Glauber's and epsom salts iron chloride potassium iodide (0.5 per cent), extracts of plant drugs and water flavored with cinnamon oil For impure blood debility malaria etc. Fraudulent therapeutic claims—[N J 22308 November 1934]

Thersol—Thersol Corporation Detroit Composition Essentially a watery solution of calcium sodium potassium and magnesium chlorides For various types of rheumatism nervous breakdown high blood pressure heart flutter etc. Fraudulent therapeutic claims—[N J 22309 November 1934]

St Joseph Merolline Petroleum Jelly—Plough Sales Corp Memphis Tenn. Composition Petroleum Misbranded because contents less than amount declared also because of fraudulent therapeutic claims as a remedy for wounds piles sore throat coughs etc—[N J 22310 November 1934]

Williams S L K Formula—Williams Laboratories Kansas City Mo Composition Essentially plant drug extracts including nuxvomica and a laxative methenamine pepsin glycerin alcohol (22 per cent) and water Misbranded because alcohol content falsely declared and because of fraudulent therapeutic claims as a remedy for liver kidney and stomach disorders rheumatism etc—[N J 22312 November 1934]

Blue Bell Liniment—Commercial Laboratories Inc Newark N J Composition Essentially a petrolatum oil such as kerosene with small amounts of camphor oleoresin of red pepper and the oils of thyme and eucalyptus For coughs sore throat rheumatism stomach ache, dyspepsia colic stiff joints etc. Fraudulent therapeutic claims—[N J 22313 November 1934]

Vio Liquid Antiseptic—Commercial Laboratories Inc Newark N J Composition Not stated except that bacteriological examination showed it to be not antiseptic Fraudulent therapeutic claims—[N J 22313 November 1934]

King Menthol (King Menthe Salve)—King Mfg Co Ltd Couder sport Pa Composition Essentially petrolatum with small amounts of menthol wintergreen and eucalyptol For coughs catarrh piles skin eruptions inflammations asthma bronchitis deafness eczema hay fever pneumonia rheumatism ulcers etc. Fraudulent therapeutic claims—[N J 22314 November 1934]

Davis Vegetable Nervine—Devore Mfg Co Columbus Ohio Composition Essentially ammonium sodium potassium and lithium bromides plant drug extracts including valerian sodium benzoate sugar and water flavored with lemon oil Misbranded because representation that it was entirely vegetable was false and misleading and also misbranded because fraudulently represented as an effective treatment for nervous disturbances hysteria drunkenness epilepsy sciatica etc—[N J 22318 November 1934]

AGGLUTINATION TESTS BEFORE TRANSFUSION

To the Editor—After a patient has had a blood transfusion from a donor whose blood has matched is it safe to give the same donor's blood a second time later without rematching that is is the patient likely to develop any incompatibility against a blood that has matched after having received a dose of the blood? If blood has matched and the patient receives blood from other donors in the meantime is it safe to give blood from the previously matched donor at a later date? If any incompatibilities are likely to develop how much time elapses before their development and what are the nature and seriousness of the reaction?

RALPH MOSTELLER, M D Spartanburg S C

To the Editor—Some discussion has come up recently in this hospital concerning the typing and cross matching for transfusions Do you consider it necessary to recross-match a patient and donor if a repeated transfusion is necessary? Is it necessary to cross-match the patient and donor in a repeated transfusion if the cross matching was all right originally but if another donor has been used for that patient in the interval? Does the type of the recipient change after one or more transfusions? Do prolonged high temperature blood stream infections or jaundice affect the type and consequently the cross-matching of the patient's blood with a prospective donor? Can the same donor be used repeatedly for small transfusions provided not more than 1000 cc. has been used without any further cross matching of patient and donor? Give references if possible Please omit name

JAMES W WALTON M D Middletown, N Y

ANSWER—Whenever the same patient is given more than one transfusion, cross-matching must be repeated before each transfusion, no matter whether it is the same donor that is to be used again or not This is required because "agglutinins and hemolysins originally absent may have developed against a donor's blood when the donor is used more than once in the transfusion of the same patient" (Thalhimer, William Hemoglobinuria After a Second Transfusion with the Same Donor, THE JOURNAL OF BLOOD TRANSFUSION, Springfield, Ill, Charles C. Thomas, 1935, p 45) Other immune reactions are possible also The problems of the development of incompatibilities under the conditions in question have not been studied thoroughly Based on our knowledge of the production of antibodies under other conditions it may be assumed that, following transfusion under suitable conditions antibodies may begin to develop in a few days The disturbances that may be caused by transfusion when 'incompatibilities' have developed as a consequence of previous transfusion may be serious even fatal hemolysis and hemoglobinuria may occur and also perhaps reactions of anaphylactic nature.

It would not be advisable to use the same donor repeatedly even for small transfusions without cross-matching before each transfusion.

The group of the blood of the recipient does not change after one or more transfusions in prolonged high fever in blood infection or in jaundice In fact so far as known the blood group of a person does not change under any circumstances

GOLD SALTS IN ARTHRITIS

To the Editor—Please tell me what you know about the gold salts treatment for chronic arthritis as described by Dr Jacques Forestier at the meeting of the American Academy of Orthopedic Surgeons in the Waldorf Astoria Hotel in New York Is it any good? Where can I get in touch with Dr Forestier? Please omit name

M D New York

ANSWER—The address is Dr Jacques Forestier Villa Forestier Avenue d'Alibon, Aix Les Bains, Savoie France. The treatment that Dr Forestier employs is the gold salt treatment, which was originally proposed by Möllgaard of Copenhagen in the treatment of tuberculosis

There seem to be no American statistics that evaluate the benefit of this preparation Forestier uses it chiefly in atrophic or rheumatoid arthritis He uses, in addition, orthopedic treatment such as plaster splints, supports and physical therapy, including baths

The injections are given weekly for a period of two or three months which constitutes a series A series may be repeated. The injections are intramuscular

The paper read by Forestier in New York before the American Academy of Orthopedic Surgeons was on the early stages of ankylosing spondylitis (Strümpell-Marie's disease)

Forestier carried out trials in more than 500 cases of rheumatoid arthritis, in which he claims he has had more success with gold salts than with any remedy employed previously. He employs the intramuscular route and states that the gold salts should be given by a skilled nurse. He uses gold sodium thiomalate (containing 50 per cent of gold) in oil suspension. This may be given in weekly injections of from 0.1 to 0.2 Gm. The total amount for one series should be between 15 and 2 Gm. Several series should be given successively with intervals of from six to eight weeks.

He states that in more than 500 cases from 70 to 80 per cent responded well to gold therapy. Among these, 50 per cent of recent cases and from 20 to 30 per cent of more than two years' duration have been permanently cured by from two to five series of injections and remained cured with no further treatment for two or three years.

He favors the complementary use of endocrine preparations and physical therapy after the inflammatory process has subsided. Forestier's hypothesis is predicated on the theory that development of rheumatoid arthritis is accompanied by tuberculous infections but that it requires another infective element, such as infected tonsils or teeth, to precipitate it. Gold sodium thiomalate appears to Forestier to be a means of treatment for rheumatoid arthritis, and this condition is amenable to cure in a considerable proportion of early cases.

The reader may be interested in an article by Dr. Forestier entitled "Rheumatoid Arthritis and Its Treatment by Gold Salts" (*Lancet* 2 646 [Sept 22] 1934).

It is perhaps significant that Forestier's gold compound also contains sulphur, as the latter is in considerable repute of late in the treatment of arthritis. It would be better, probably, not to give too much consideration to Forestier's treatment until it has had some confirmation. Furthermore, the use of gold compounds has been recommended from time to time for this or that condition, but in general their therapeutic value is little. The Council on Pharmacy and Chemistry has not accepted any gold preparations for use in the treatment of rheumatism.

EVIDENCE OF GONORRHEAL INFECTION

To the Editor—I have been consulted by a young woman on whom I operated in March 1931 for acute suppurative appendicitis. I removed the appendix through a McBurney incision but I had a very clear view of the uterus, tubes and ovaries. The uterus was of normal size and in good position and the tubes and ovaries were normal in every way. There were no adhesions. The wound was closed without drainage and the patient was discharged from the hospital on the seventh day in excellent condition. She has never had any trouble since the operation and except for an attack of otitis media followed by a mastoid infection in 1934 she has never lost a day's work since the appendix operation. A few days ago some one told the young man to whom she is engaged that she had an attack of gonorrhea in December 1930. She came to me very much disturbed and insisted that I examine her. My examination gave no evidence that she has now or ever has had an infection of Skene's glands, urethra, Bartholin's glands or cervix. There is no erosion of the cervix. The uterus is in good position, freely movable, and there are no masses in the region of the tubes and ovaries. There is no tenderness anywhere in the pelvis. Smears from the urethra were negative. Smears from the cervix and vagina showed a few epithelial cells, no pus cells and no gonococci. There were a large number of lactic acid bacilli present. Is there any test that I can make or have made that will prove that this young woman was never infected with gonorrhea? I have treated hundreds of women for gonorrhea both in private practice and in a venereal disease clinic and I have never seen a patient so thoroughly well of gonorrhea that some evidence of past infection was not present. Does not gonorrhea in the female almost always cause change that may be recognized several years later? Please omit name.

M. D.

ANSWER.—If this patient really was infected by gonorrhea in December 1930 and if she was operated on in March 1931 and if at that time the uterus, tubes and ovaries were normal in every way, one may state that there was no evidence of gonorrheal involvement of the internal genital tract of this patient at that time.

In view of the fact that a recent examination shows no evidence of antecedent infection in Skene's glands, in the urethra, in Bartholin's glands or in the cervix and if at the present time there is no erosion of the cervix and the uterus is in good position and freely movable and there are no masses present, furthermore coupled with the fact that the smears from the urethra, cervix and vagina are negative at this time, the statement that there is no evidence of an antecedent gonorrheal infection is justified. One might discuss the advisability of making a gonococcus fixation test. Its value, however, under the circumstances, might be questioned.

From the evidence submitted, there appears to be no proof that this patient has or has had a gonorrheal infection.

ARTERIOSCLEROSIS OBLITERANS

To the Editor—I have under my care a woman aged 73 who complains of coldness in both feet, which is aggravated by walking and relieved by the local application of heat. There are absent pulsations in the dorsal pedis and posterior tibial arteries. Roentgen examination reveals calcification of the vessels in both legs. The Wassermann reaction is negative. She has an auricular fibrillation and partial heart block and at times complete heart block. The coldness is not constant and often passes off without any treatment. Occasionally there is blanching of the extremities in the elevated position and congestion in the dependent position. Vasodilators, positional exercises, contrast baths, baking and massage have been tried without any improvement. What other methods of treatment can you suggest? What is your opinion of local diathermy or intravenous saline solution as promising methods of relief? Please omit name.

M. D., New York.

ANSWER.—The advanced age of the patient and the calcification and occlusion of the arteries of the extremities indicate the presence of arteriosclerosis obliterans. The claudication in the legs with a given amount of exercise is caused by diminished volume flow of blood to an actively contracting muscle. The arteriosclerotic process probably is general and probably is the basis of the cardiac disease, fibrillation and partial incomplete heart block. In patients of this age it is not advisable to carry out any drastic treatment. Protection against excessive use of the feet, preservation of normal warmth with woolen hose and great care in the trimming of nails to prevent injury are important, as ulcers or gangrene frequently follow some minor abrasions or injury to the skin. The possibility of diabetes should be considered. It is present in about 30 per cent of the cases of arteriosclerotic disease of the extremities. Vasodilators usually do not give relief of the symptom of claudication. Postural exercises and contrast baths may be used in moderation, the latter not more than three times a week, to prevent excessive soaking of the skin. The effects of local diathermy are too transient to justify the trouble and expense. Intravenous injection of saline solution or fever induced by the administration of foreign protein is not advisable, for this may change the coagulation properties of the blood and favor further thrombosis when patients are of this age. Collateral circulation develops slowly in old, arteriosclerotic subjects. Their expectancy of life is definitely diminished. With organic cardiac disease, the disability in the legs may be useful in restricting the patient's sphere of activity, thus giving an additional safeguard to the heart. The newer tissue extracts, such as are obtained from the pancreas and from the skeletal and cardiac muscles, frequently give considerable relief from the pain of claudication and enhance the ability to walk.

NEO-MERPHENOL

To the Editor—Kindly mail me some information regarding Neo-Merphenol, by Lynch & Co. Kansas City, Mo. and Los Angeles.

S. A. VAN HOFFEN, St. Louis.

ANSWER.—The information on Neo-Merphenol that is in the files of the Council on Pharmacy and Chemistry is rather meager. An advertising circular received in November 1934 shows that the preparation is marketed with the claim that it is "A Blood Antiseptic that has been tried and not found wanting." The only hint as to the composition of the preparation occurs in the statement that it "is a pure chemical in which the mercury atoms have been combined to the carbon atoms of the benzene [sic] ring." This statement suggests relationship with the phenyl mercury compounds, which have recently come into use as bactericidal agents. However, cursory tests recently made in the A. M. A. Chemical Laboratory seemed to indicate that Neo-Merphenol contains a substance closely allied to it but not identical with the organic mercury compound known as metaphen (see New and Nonofficial Remedies, 1935, p. 314).

The A. M. A. Chemical Laboratory requested the distributors of Neo-Merphenol (Lynch & Co.) to supply a quantitative statement of the composition of the product in order that the information might be transmitted to inquiring physicians. The firm's attention was also called to the fact that a specimen of Neo-Merphenol in the Council's files contained particles of such large dimension as to render intravenous injection of the product extremely hazardous. No reply having been received to the Laboratory's request, a second request was sent the firm by registered mail. This, too, failed to elicit a response from Lynch & Co.

The claims advanced in the advertising circular are extravagant and on the whole unsupported by scientific evidence. Furthermore, it is dangerous to use, particularly by intravenous injection, a substance the composition of which is unknown. THE JOURNAL has repeatedly called attention to the added responsibility which a physician assumes when he injects such a preparation into his patient.

ROENTGEN IRRADIATION OF BRAIN IN
JACKSONIAN EPILEPSY

To the Editor—A friend of mind had Jacksonian epilepsy from 1899 to 1913. In the latter year a trephining was carried out and a small fibro-endothelioma of hazelnut size was removed from the center of the left hand and arm. Up to 1925 there was no trouble, but following a nervous breakdown which started under severe mental strain during a demonstration of experimental epilepsy coupled with overwork, there have been difficulties from time to time. During overwork or special stress and especially during heat waves when in addition sleep is poor the left hand and arm constantly enter into consciousness often with marked apprehension that an attack of the former malady may recur. Possibly gradual overweight of the patient, now 48 years old may be a factor in giving an extra difficulty during hot weather (210 pounds or 95 Kg net, 5 feet 10 inches or 178 cm tall). In my opinion the scar left on the brain surface by the operation is the physical factor behind the difficulties in discussing the matter one of the younger x-ray men suggested that about four short intensive x-ray treatments could do no harm but might do considerable good we were thinking of a possible softening of the scar tissue. However my friend knows what he has the temporary paralysis of the left arm following immediately after the operation has completely vanished, so that he now can operate a typewriter perfectly well by the touch system and he is somewhat reluctant to accept the suggestion of probable benefit. I shall therefore appreciate it if you will try to answer these two questions: 1 What is the evidence in favor of roentgen treatment of these conditions? 2 Has benefit been obtained by such treatment in similar cases? Please omit name.

M D Illinois

ANSWER—Whether or not exposure of the affected region of the brain to repeated, but moderate, doses of roentgen rays would lead to improvement in a case such as this is uncertain. It could be tried without danger provided the doses used do not exceed 500 roentgens per field. This might be repeated three or four times at intervals of one month. Larger doses, that is, doses approximating the limit of tolerance of the skin, might lead to increase rather than decrease in the amount of fibrous tissue present and hence should be carefully avoided. Reports of improvement in similar cases have not appeared in the literature, but the effect of such treatment in keloids and scars in general is well known.

DERMATALGIA

To the Editor—A farmer aged 60 has been troubled with a burning stinging sensation occurring over various parts of the body especially the face abdomen and thigh. These sensations occur chiefly at night, they can be relieved by pressure. There are no objective signs of any skin lesions. Diagnoses of paresthesia rosea and universal pruritus have been made. Up to the present time the patient has been very resistant to local therapy. I would appreciate suggestions as to treatment. Please omit name and address.

M.D., Iowa.

ANSWER—This is a case of the rare disorder called dermatalgia, a disease of the nerves of the skin causing no visible change in the skin. A Wassermann and Kahn test should be made on the blood serum and a cell count globulin tests, Wassermann and Kahn test and colloidal gold or mastic tests on the spinal fluid. Dermatalgia should always arouse suspicion of tabes dorsalis. If this is ruled out, the possibility of malaria, diabetes, rheumatism, leukemia or another form of lymphoblastoma or leprosy should be considered. If no etiologic factor can be discovered, quinine, arsenic or the salicylates may be used empirically. Alternating applications of a hot water bag and ice bag may be tried, faradism, or hot baths followed by a thick dry cotton dressing. Hyperesthesia of the skin often accompanies dermatalgia therefore the clothing should be nonirritating and talcum powder should be used freely.

SUBLUXATION OF SACRO ILIAC SYNCHONDROSIS

To the Editor—Your discussion under Queries and Minor Notes in the issue of Dec. 15 1934 of Subluxation of Sacro-Iliac Synchondrosis was very interesting to me. But a more fundamental question seems to be the pathology and diagnosis of the condition also etiology. I think a discussion of this would be profitable.

E. C. McCulloch M D Staten Island, N Y

ANSWER—The whole subject of sacro-iliac subluxation is in a controversial state. The opinions vary from that of Goldthwait, who believes there is such a lesion to those who deny categorically that there is such a lesion.

The pathologic changes occur chiefly in the internal and external ligaments. The diagnosis is based on the history of injury by pain, tenderness and asymmetry of the pelvis.

The pain is usually localized to the region of the joint affected and may follow the course of any of the nerves of the lumbosacral plexus especially the first, second and third sacral components. The most common areas of referred pain are down the back of the leg down the side of the leg, and to the region of the superior gluteal nerve in the buttock.

Roentgen observations are usually negative. Some believe that the roentgenogram will show a partial slipping. This is not generally accepted.

It is hoped that derangements of the sacro-iliac joint will in the near future be understood like internal derangements of the knee joint. But this will probably never be realized because of the relative inaccessibility of the sacro-iliac joint.

TREATMENT OF SYPHILIS

To the Editor—A man aged 40 had a chancre eight years ago. After secondary eruptions appeared he received four injections of arsphenamine and a few intramuscular injections presumably of mercuric salicylate, over a period of about four weeks. Treatment was then discontinued. Examination at this date shows a 4 plus Wassermann reaction. The entire physical examination is negative. There has been no history of any illness except an occasional neuritis of the right leg which he states antedated the chancre by two years. The spinal fluid has not been examined. Should this case be treated according to the scheme of treatment outlined for early syphilis by Stokes and others in *THE JOURNAL*, April 21 1934? If not will you kindly point out the necessary changes or outline the proper treatment? Kindly omit name.

M D, New York.

ANSWER—The early treatment in this case was entirely inadequate and of too short duration. The case should be reclassified as a late asymptomatic syphilis, although a more careful examination would probably reveal some evidence of structural change in the cardiovascular or nervous system. The treatment for late syphilis is a combined treatment beginning with iodides by mouth, followed by alternate courses of a heavy metal, either mercury or bismuth compounds, and one of the arsphenamines. Treatment should be continued, with short periods of rest between courses until the Wassermann reaction becomes negative. There is no definite scheme of treatment for late syphilis, as much depends on the condition of the affected organs and the natural resistance of the patient. Many authorities advocate prolonged intermittent treatment over a period of many years in preference to the continuous plan. A great deal depends on how well patients past middle age tolerate intensive therapy, and the treatment may have to be modified accordingly. In general, the greatest reliance should be placed on iodides and on preparations of mercury and bismuth.

FIBROIDS IN PREGNANCY WITH CESAREAN SECTION

To the Editor—Can you state the incidence of cases in which a uterine fibroid completely obstructing pregnancy has required cesarean section followed by hysterectomy? I have searched the various text books and quarterly index but am still far from satisfied. Would such a case be of sufficient interest to report? Any information as to incidence or with references will be appreciated.

FRANK J CLARKE, M D Brooklyn

ANSWER—There are no statistics giving specifically the number of cases in which uterine fibroids have completely obstructed labor, requiring cesarean section and hysterectomy. Such cases are, of course, not common but they occur in the practice of every busy obstetrician. Fibroids, during pregnancy, are found in percentages varying from 5 to 15, depending on the part of the country they come from and the accuracy of observation, but it is exceptional that they completely block the passage. Often nature lifts them out of the pelvis during the latter months of pregnancy or in labor itself, allowing the child to slip by them.

Nor is it always necessary to extirpate the fibroids at the time of cesarean section. Often the hysterectomy becomes so formidable that the wiser policy would be to remove the child, leaving the fibroid for subsequent extirpation when the intense vascularization of the pelvis accompanying pregnancy has subsided. Indeed, unless the operator is exceptionally skilful this should be the rule. Reporting of such a case would be interesting but would not add much to our general knowledge.

VASOSTOMY

To the Editor—What is the present status of vasostomy with injection of the seminal vesicles in chronic seminal vesiculitis of nonspecific origin? The patient in question has been treated by massage vaccines and foreign protein with no relief. More radical measures must be undertaken because of an associated arthritis of the same duration as the vesiculitis. What are the chances of sterility resulting?

M D., Ohio

ANSWER—Vasostomy with injection of the seminal vesicles in chronic seminal vesiculitis is rarely being used at the present time. This operation does not enjoy the popularity that it did ten years ago. Papers dealing with the end results of the operation are few and far between. H. L. Kretschmer published a paper in *THE JOURNAL*, March 19, 1927, entitled "The Persistence of Symptoms after Vasostomy."

In many instances, failure to obtain relief is due to the presence of strictures in the urethra. It may be well to explore for strictures and if they are present to pass large sounds before undertaking any radical measures. It is always well to locate possible foci of infection in other parts of the body, such as the teeth, sinuses and tonsils.

Among urologists at this time the consensus on this subject is to the effect that vasostomy does not cure seminal vesiculitis. This view no doubt is responsible for the rare intervals at which vasostomy is done.

The chances of sterility resulting from the operation are great, in other words, a large number of patients are rendered sterile by it.

ANALGESIC DRUGS

To the Editor—I would appreciate information as to what drug or drug combinations to be taken by mouth you would recommend as having the most powerful analgesic effect with little or no hypnotic effect.

HARRY G. ARMSTRONG, M.D., Dayton, Ohio

ANSWER—A combination of analgesics acting in different ways is assumed according to Bürgi's rule to be more efficient than any one of them alone. For instance, the following combination of one half of the average U S P dose of the following analgesics with a smaller relative dose of extract of hyoscyamus—to antagonize possible sweating and yet not produce troublesome dryness of the mouth—is likely to relieve pain with less undesirable by-effects than if a larger dose of any one were taken.

Extract of hyoscyamus	0.15 Gm
Phenobarbital	0.25 Gm
Acetanilid	1.50 Gm
Acetylsalicylic acid	2.50 Gm

Mix and divide into fifteen capsules.

Label: One every hour until relieved or until three are taken then every two to four hours as required.

For the relief of very severe pain such as that of gallbladder or renal colic, a dose of 0.03 Gm of codeine phosphate per capsule, or 0.45 Gm for the fifteen capsules, might be added with great advantage.

DEATH BEFORE ACCIDENT

To the Editor—I should like a medical opinion about a certain problem that has arisen in my practice. Two cars were wrecked by a head-on collision and the occupants of both cars injured severely; one occupant being rendered unconscious and riding alone and the occupants of the other car being severely bruised and cut for one of these and the other member of this car was found dead. The driver of the car who was riding alone has been indicted for manslaughter and he is contending that the person who was found dead in the other car involved was already dead at the time of the wreck on these grounds. The wreck occurred at night and the dead person had been drinking rather heavily that afternoon and night according to witnesses and in spite of the complete wreck of the car in which the dead person was found and the severe and extensive lacerations of the face, neck and crushed chest there was no blood on the dead person. The question is whether one could have such severe lacerations and have no bleeding unless dead for some time. I am coroner and was called to the wreck and found the dead person in the car and mangled badly but none of the cuts and lacerations were oozing blood. I saw her thirty or forty minutes after the wreck. What are the chances of the person being dead at the time of the wreck?

M.D., North Carolina

ANSWER—In the complete absence of bleeding from the cuts and lacerations there would seem to be no other explanation of the situation as described than that the person was dead when the collision occurred. A thorough postmortem examination would have been of great interest in a case like this.

SODIUM CITRATE IN BLOOD TRANSFUSION

To the Editor—1. Is U S P sodium citrate diluted with triple distilled water and subsequently autoclaved suitable and adequate for intravenous use in blood transfusions? 2. A 10 per cent solution of 2.5 per cent sodium citrate is usually recommended to prevent clotting. I have occasionally seen a few clots in blood so treated and well mixed. Is there any reason why a greater strength of citrate than this should not be used in doing a transfusion of say 500 cc? Kindly omit name.

M.D., Michigan

ANSWER—1. It is best to use the chemically pure sodium citrate of C P reagent quality, diluted with triple distilled water and subsequently autoclaved for blood transfusions. Any other type of citrate solution is apt to give reactions. Some practitioners have used for many years a 2 per cent sodium citrate solution, lukewarm, which if properly made and chemically pure should prevent clotting. If the solution is stronger than that it is apt to produce marked reactions, and if weaker than that it produces clotting.

2. Richard Lewisohn of the Mount Sinai Hospital of New York has laid down every detail of the citrate method and found that the best solution is a 2 per cent solution of chemically pure sodium citrate.

USE OF DIPHTHERIA TOXOID

To the Editor—Kindly advise me whether there would be danger of severe reaction from the injection of a single dose of diphtheria toxoid alum precipitated in a child aged 13 years who has had numerous asthmatic attacks. Kindly omit name.

M.D., Illinois

ANSWER—If there is little or no danger of exposure to infection with diphtheria, postponement of the injection of toxoid should be considered. If it seems necessary to give toxoid it would be better to determine beforehand whether the patient is susceptible to diphtheria. He may be insusceptible especially if he has been living in a community where diphtheria is prevalent. In case toxoid must be given, probably there would be less danger of any severe reaction if the "single dose" should be injected in several instalments at intervals of four or five days.

TRAUMA AND ANEMIA

To the Editor—A married woman aged 62 was in perfect health until she sustained a fractured tibia in an automobile accident one and a half years ago. About one month following the accident, typical pernicious anemia developed. To me this appears nothing more than a coincidence but as she is endeavoring to establish a causal relationship in court (the case is coming up shortly) I should appreciate your opinion in the matter. Please omit name.

M.D., New Jersey

ANSWER—There is no known relationship between trauma of the type described and the appearance of true pernicious anemia. Pernicious anemia appears in individuals of a definite constitutional type, and the blood changes are primarily related to the defective function of the stomach secretions. If the injury had produced these pathologic changes in the stomach (which is extremely improbable), it is unlikely that the anemia would have appeared in less than two years, if the patient had been perfectly well previous to the accident. In complete gastric resection the appearance of the anemia usually does not appear until this period of time has elapsed.

NEOARSPHENAMINE IN FURUNCULOSIS

To the Editor—In *Queries and Minor Notes* (THE JOURNAL, July 27, p. 304) is a statement on persistent furunculosis. Some seven or eight years ago as the result of my using neoarsphenamine intravenously in the treatment of certain types of infection in the urinary tract I suggested to the clinicians in the Jackson Clinic that they employ neoarsphenamine intravenously in some cases of recurrent furunculosis.

I cannot say without reviewing our records how many cases of recurring or recurrent furunculosis we have treated but there have been many and again without reviewing the records I cannot say but I cannot recall a case that was not decidedly benefited if not cured by the intravenous injection of neoarsphenamine 0.3 Gm at five day intervals. Many of these patients had had the customary vaccines, roentgen therapy and diets. Several patients have had recurrences but they would immediately report and request the treatments.

Our records show one case in which a young boy who was operated on for an appendiceal abscess misplaced his wound dressing and scratched the abdominal skin about the wound. Along these scratch marks there developed many papulovesiculopustular lesions. They were treated by the usual method of opening them and applying various antiseptic solutions. Numbers continued to appear about the wound and over the entire abdomen, chest and other portions of the body. They were opened and antiseptic solutions applied. The patient was in very poor general condition. In spite of the local treatment the lesions continued to appear and were extremely painful although superficial in nature. Following one or two injections of neoarsphenamine no new lesions appeared and within a few days all the old lesions had entirely regressed.

I do not wish to convey the meaning that the use of neoarsphenamine is specific for all cases of furunculosis. Yet every member of our staff has been markedly impressed and exceedingly pleased with the results of this form of treatment.

During the past few days while some case records of pernicious abscess were being reviewed one case was found in which there was a preceding history of carbuncle followed by recurring furuncles on the back of the neck. Following admission of the patient to the hospital, furuncles continued to develop over the hands, arms and various parts of the body. Several days following the incision and drainage of the abscess several furuncles developed at various sites. The patient was given an injection of neoarsphenamine and during an interval of five days two new lesions developed. Following the second injection of neoarsphenamine no new lesions developed and the old ones rapidly subsided. A discharge note made several weeks later stated that no furuncles had developed since the last injection.

GEORGE H. EWELL, M.D., Madison, Wis.

Council on Medical Education and Hospitals

ORGANIZED AND COURTESY STAFFS OF GENERAL HOSPITALS

A Study by the Council on Medical Education and Hospitals of the American Medical Association with the Cooperation of the Council of the American Hospital Association

What is the typical relation of hospitals to physicians in the average community? Do physicians generally share in the facilities of the hospitals and to what extent? In the hospital number for 1933 of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION it was stated that 126,261 physicians had hospital connections, 101,518 being on the staffs (organized and courtesy), 2,018 were resident physicians, 7,757 interns and 2,437 hospital executives. The total is 78 per cent of 161,359 physicians, the total number of physicians in the United States as given by the American Medical Association Directory for 1934.

The facts in the following paragraphs resulted from a questionnaire prepared jointly by the bodies mentioned above. This was sent to 2,936 general hospitals throughout the United States, excluding (a) those owned and operated by govern-

ments, national state or local (b) those organized for profit (c) those in cities and towns of more than 250,000. The reason for excluding the hospitals in the large cities was that the staff situation is generally different in metropolitan centers as compared with medium-sized and smaller places and most of the teaching institutions are located in these large cities.

Answers were received from 1,332 of the hospitals addressed, and statements in this report are representative only of those hospitals which returned the questionnaire.

Most of these hospitals have both organized and courtesy staffs. An organized staff is a group having a definite advisory relation to the governing body of the hospital such as the board of trustees and being responsible for the professional work of the hospital. The courtesy staff is made up of all or certain of the physicians in the locality not members of the organized staff who may hospitalize patients in the hospital sometimes under certain restrictions. The average organized

staff was found in this study to consist of twenty-six physicians, the average courtesy staff of twenty.

Table 1 gives information with regard to organized and courtesy staffs and the number of staff members in the 1,332 responding hospitals. Of these, 971 (or 73 per cent) have organized staffs and 876 (or 66 per cent) have courtesy staffs. In the Middle Atlantic states 92 per cent of the hospitals reported organized staffs, and in the Pacific states only 54 per cent reported organized staffs.

TABLE 4—Attendance at Staff Meetings

More than half the organized staff	692
Between 25 and 50% of the organized staff	206
Less than 25% of the organized staff	23
Not given	28

As to courtesy staffs, 81 per cent of the reporting hospitals in the Middle Atlantic states claimed to have them, while only 40 per cent in the Mountain states had them. Table 2 gives the information.

It is reported that staff meetings are usually held monthly and are fairly well attended. More than four fifths of the staffs hold monthly meetings. One staff in ten holds meetings oftener and a very few hold them less often.

Better than 50 per cent attendance of staff members was reported by 71 per cent of the hospitals having staffs (table 4).

Apparently the practice in about half of the hospitals is to invite the courtesy staff members to attend the organized staff meetings. The questionnaires show that 46 per cent of the hospitals having courtesy staffs permit these physicians to participate in regular staff meetings (table 5).

The study endeavored to determine how important courtesy staff members were to the hospital's occupancy. It was found that an average of 15 per cent of the patients admitted during 1933 in hospitals having courtesy staffs were admitted by physicians on the courtesy staff. The number of patients so

Total patients admitted in these 520 hospitals (1933)	916,230
Percentage admitted by courtesy staff	16.0

admitted ranged from half of all those admitted in Washington hospitals having courtesy staffs to only 7 per cent admitted to Arkansas hospitals. The part played by courtesy staffs in keeping the hospital beds occupied was greatest in the New England states, where they admitted 25 per cent of all patients, and in the Pacific states, where they admitted 24 per cent of all patients. The proportions in the Middle Atlantic and Southern states range between 12 and 15 per cent, in most of the Central states between 18 and 20 per cent. The information on the number of patients admitted by courtesy staff members may be summarized as in table 6 for the whole country.

SUMMARY

It appears that the majority of voluntary hospitals in our smaller cities have both organized and courtesy staffs, have monthly staff meetings in which courtesy staff members often participate, and have better than 50 per cent attendance at these meetings. Where courtesy staffs exist, they admit on the average one sixth of the patients entering the hospital, but this figure shows wide variations.

Medical Examinations and Licensure

COMING EXAMINATIONS

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY. Written examination and review of case histories of Group B applicants will be held in various cities of the United States and Canada. Dec. 7. *Applications must be filed not later than Nov. 1.* Sec. Dr. Paul Titus, 1015 Highland Bldg. Pittsburgh (6).

AMERICAN BOARD OF OPHTHALMOLOGY. The Cincinnati examination previously announced, will not be held. The next examination will be given in St. Louis Nov. 18. *Application must be filed before Sept. 15.* Sec. Dr. William H. Wilder, 122 S. Michigan Ave. Chicago.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY. St. Louis Jan. Sec. Dr. Fremont A. Chandler, 180 N. Michigan Ave. Chicago.

AMERICAN BOARD OF OTOLARYNGOLOGY. Cincinnati Sept. 14. Sec. Dr. W. P. Wherry, 1500 Medical Arts Bldg. Omaha.

AMERICAN BOARD OF PEDIATRICS. Philadelphia Oct. 10 and St. Louis, Nov. 20. Sec. Dr. C. A. Aldrich, 723 Elm St. Winnetka Ill.

AMERICAN BOARD OF RADIOLOGY. Detroit, Dec. 12. Sec. Dr. Byrl R. Kirklun, Mayo Clinic, Rochester, Minn.

ARIZONA Basic Science. Tucson Sept. 17. Sec. Dr. Robert L. Nugent, Science Hall, University of Arizona, Tucson. *Medical.* Phoenix Oct. 12. Sec. Dr. J. H. Patterson, 826 Security Bldg. Phoenix.

COLORADO. Denver Oct. 1. Sec. Dr. Harvey W. Snyder, 422 State Office Bldg. Denver.

GEORGIA. Atlanta Oct. 8-9. Joint Secretary State Examining Boards Mr. R. C. Coleman, 111 State Capitol. Atlanta.

IDAHO. Boise Oct. 1. Commissioner of Law Enforcement Hon. Emmitt Post, 205 State House. Boise.

MICHIGAN. Lansing Oct. 8. Sec. Board of Registration in Medicine Dr. J. Earl McIntyre, 202-34 Hollister Bldg. Lansing.

MINNESOTA Basic Science. Minneapolis Oct. 12. Sec. Dr. J. C. McKinley, 126 Millard Hall, University of Minnesota. *Minneapolis Medical.* Minneapolis Oct. 15-17. Sec. Dr. Julian F. Du Bois, 350 St. Peter St. St. Paul.

MONTANA. Helena Oct. 1. Sec. Dr. S. A. Cooney, 7 W. 6th Ave. Helena.

NATIONAL BOARD OF MEDICAL EXAMINERS. The examination will be held in all centers where there are Class A medical schools and five or more candidates desiring to take the examination. Sept. 16-18. Ex. Sec. Mr. Everett S. Elwood, 225 S. 15th St. Philadelphia.

NEW HAMPSHIRE. Concord Sept. 12-13. Sec. Board of Registration in Medicine Dr. Charles Duncan, State House. Concord.

NEW JERSEY. Trenton Oct. 15-16. Sec. Dr. Arthur W. Belting, 28 W. State St. Trenton.

NEW MEXICO. Santa Fe Oct. 14. Sec. Dr. Le Grand Ward, Sena Plaza. Santa Fe.

NEW YORK. Albany Buffalo New York and Syracuse, Sept. 16-19. Chief Professional Examinations Bureau Mr. Herbert J. Hamilton, 315 Education Bldg. Albany.

PUERTO RICO. San Juan, Sept. 3. Sec. Dr. O. Costa Mandry, Box 536. San Juan.

RHODE ISLAND. Providence Oct. 3-4. Dir. Department of Public Health Dr. Edward A. McLaughlin, 319 State Office Bldg. Providence.

WISCONSIN Basic Science. Madison Sept. 21. Sec. Professor Robert N. Bauer, 3414 W. Wisconsin Ave. Milwaukee.

WYOMING. Cheyenne Oct. 7. Sec. Dr. G. M. Anderson, Capitol Bldg. Cheyenne.

Nebraska June Examination

Mrs. Clark Perkins, director, Nebraska Bureau of Examining Boards, reports the written examination held in Omaha, June 11, 1935. The examination covered 10 subjects and included 92 questions. An average of 75 per cent was required to pass. Eighty-eight candidates were examined, all of whom passed. The following schools were represented:

School	PASSED	Year Grad	Number Passed
Creighton University School of Medicine (1934-6)	(1935-19)		25
University of Nebraska College of Medicine (1934-5)	(1932-2)		63
	(1935-56)		

Five physicians were licensed by reciprocity and 1 physician was licensed by endorsement from January 11 through July 24. The following schools were represented:

Book Notices

The Patient and the Weather. By William F. Petersen, M.D., with the Assistance of Margaret E. Milliken, S.M. Volume II. Autonomic Dysfunction. Cloth. Price \$6.50. Pp. 530 with 249 illustrations. Ann Arbor, Mich. Edwards Brothers Inc. 1934.

The Patient and the Weather. By William F. Petersen, M.D., with the Assistance of Margaret E. Milliken, S.M. Volume III. Mental and Nervous Diseases. Cloth. Price \$5. Pp. 375 with 192 illustrations. Ann Arbor, Mich. Edwards Brothers Inc. 1934.

This is an interesting study of an insistent problem. Every physician who has studied mental disorders or conditions bordering on the mental recognizes that the weather has a definite effect on the activity and the welfare of his patients. Many students of the problem have attempted to keep charts, but nothing consistent has been reported and the present study is really more suggestive than constructive. It is unfortunate that the volumes have not been released in consecutive order, for the publication of volumes II and III without volume I leaves one slightly beclouded. The series will probably extend to five or six volumes. The basic theory behind the author's studies is that the individual is a product of his environment, one of the most important features of which is the weather. There are two phases in the individual's metabolism, in one of which the organism must be at any given time. One phase is characterized by anabolism, reduction and vascular constriction and the other is characterized by oxidation and dilatation of the vascular bed, as well as catabolism. Certain parallels are drawn between sympathicotonia, but a complete parallel is not found. With a change in the weather comes dilatation or spasm, and the organism's ability to react is significant. When there is an inability to respond there is disease. The individual's body type and his biochemical makeup are significant in this respect. The body reacts by these means to the various meteorological "fronts" and changes in season.

Volume II deals with such topics as focal infection, headache, epilepsy, eclampsia, mucous colitis and gastric ulcer, the neuromes, asthma, urticaria, glaucoma, diseases of the ear and the teeth, and alopecia areata. The author in each of these disorders gives a general discussion of the vascular process involved, including an analysis of the meteorological genesis of the condition. The condition is described carefully, with particular reference to relevant literature and to the vascular changes in individual cases. The cases are written up in detail, and the results of chemical examinations are given. The chapter is accompanied with tables showing clinical observations compared to meteorological conditions. At the beginning of most of the topics there is a "spot map" showing the frequency of the disorder in given geographic areas in this country. These can be compared with meteorological maps to show the relationship to weather.

Volume III, which treats of mental disorders, seems a little more clear cut than the second volume. The first eight chapters, which deal with mental disorders in general, are accompanied by excellent maps showing national distribution of the various types of mental and allied cases as well as graphs to show the monthly admissions of the various disorders to mental hospitals. In the second part of this volume are eighteen thorough case histories of psychotic patients presented to show the influence of the weather. The last part of the book consists of chapters on multiple sclerosis, tabes, dementia paralytica, poliomyelitis and meningitis. While some relationships are shown, there is no general conclusion to be drawn, for the evidence is insufficient. The study has not reached a point at which it is past the research stage, but to Dr. Petersen must be given praise for having the temerity to attack such a difficult subject, for having done a thorough piece of work and for having shown a great deal of intelligence in putting together his material. Much of it is obscure, however. Most of the illustrations are complicated graphs comparing physiologic and meteorological phenomena in and about the patient. Some of these charts are vast undertakings with as many as fifteen variants recorded. The value of the book to the physician in practice is nil except from an educational standpoint. Some chapters in each volume should be helpful to individual specialists in analyzing obscure cases, but the real use of the work will be to students of biochemistry, physiology and psychology.

Diet and Like It A Guide to Pleasant and Healthful Dieting for Those Who Would Reduce and Those Who Would Not Gain By Mabel E. Baldwin Ph.D. With an introduction by Daniel C. Darrow M.D. Assistant Professor of Pediatrics Yale University School of Medicine Cloth Price \$2.50 Pp 230 New York & London D Appleton Century Company Inc. 1935

This book is sound. It will please physicians and could be read with profit by most of them. Part 1 gives menus for the correction of obesity, clearly detailed in household measures, with the necessary explanations. Part 2 contains an excellent discussion of the general principles of nutrition and a table of food values. This presentation is simple enough to be understood easily by the interested layman. It is the most useful part of the book and, if read and applied by every housekeeper, the general health of the community would be improved. There should be a big demand for correct information, made easily available as in this book, on a subject so important as nutrition. Physicians will do well to recommend "Diet and Like It" to patients and friends. As a practical treatise on the treatment of obesity, however, Dr. Baldwin is too optimistic in the title. Obese patients will not like it. Indeed, these menus alone will not even be effective with most patients. A few of them, the careless eaters who take a roll and ball of butter thoughtlessly while waiting for dinner to be served, will be rendered food conscious by reading the book, and that will be enough. With most obese patients overeating is a fixed sensual indulgence. Such patients on these menus will not be hungry if they distinguish between hunger and the memory of the fun of eating. But they will not do this. They need firm handling by a determined physician who tells them they must give up for a time the "fun of eating" instead of "diet and like it." Such patients do better when no effort is made to pander to sensuality in appetite. A small portion of cheese at the end of a meal lets down less painfully the confirmed dessert eater. The same applies to salad dressings with a base of liquid petrolatum. These suggestions are of value more in the prevention than the cure of obesity, but so is this book.

Scientific Organizations in Seventeenth Century France (1620-1680) By Harcourt Brown M.A. Ph.D. History of Science Society Publications new series V Cloth. Price \$3 Pp 306 Baltimore Williams & Wilkins Company 1934

This book attempts to supplement Ornstein's "The Role of the Scientific Societies of the Seventeenth Century" and Morgan's "Histoire du journal des savants," the former of which the author thinks is particularly lacking in references to the ultimate sources of our knowledge of that time, namely, the books, pamphlets and letters of that period—a source material more illuminating than the documentation of modern authors, which is sometimes not especially discriminating. "Academies" prior to the seventeenth century, the author points out, were not very effective, since they were opposed by the princes and churches alike as dangerous on political and religious grounds. Scholarly historical exploitation by the authors of the manuscripts and letters and books of the savants of the time are most important in elucidating how these men of science worked and thought and just how the learned bodies and academies came into being under the guidance of certain leaders. The author has made an important and interesting contribution to the scientific status of that period. It is surprising, however, to note that no reference at all was made to the first scientific academy ever organized, Die Deutsche Akademie der Naturforscher (1652), although the origin of the Royal Society of London (1662), ten years later, comes in for a share of discussion.

Las localizaciones extra intestinales de la amebiasis (Relato oficial al V° Congreso nacional de medicina) Por el Dr. David Stameri profesor titular de clínica médica Paper Pp 212 Rosario Editorial Médica Lagos 1934

The author has collected and arranged systematically a large amount of material collected from published papers on extra-intestinal amebiasis. As stated in the introduction, he has collected what seemed to him the more interesting material and neither the experimental data nor the bibliography is complete. This incompleteness is most apparent in the omission of most of the contributions of the last few years and especially of the work of investigators in the United States. The author presents an uncritical acceptance of much material that is unsub-

stantiated and unconfirmed. No criteria of diagnosis are given, nor is any other basis presented by which the reports and data can be evaluated. The lack of critical judgment and selection, the marked incompleteness of treatment in general, reduce the value of the book for scientific use and authoritative reference. The bibliography is of value, so far as it goes.

Surgical Pathology of the Peritoneum By Arthur E. Hertzler M.D. Surgeon to the Agnes Hertzler Memorial Hospital Halstead Kansas Hertzler's Monographs on Surgical Pathology Cloth Price \$5 Pp 304 with 201 illustrations Philadelphia & London J. B. Lippincott Company 1935

This volume is one of a series of monographs on surgical pathology by the same author. If the others equal this one in quality, the entire series is excellent. The book represents the author's forty years of interest, thought, study, experience and experiment in the peritoneum. All these are reflected in its every page. The work is divided into thirteen chapters and covers the subject completely though not exhaustively from the anatomy, embryology and physiology through healing of wounds, peritonitis, changes in circulation and tumors. The questions of adhesions and peritonitis are discussed particularly fully. The book is written in clear, simple style. Its chief attraction lies in the fact that it presents not only the author's intimate knowledge of the peritoneum and its diseases but also the wisdom of a rich surgical experience. The numerous beautiful and excellent drawings and reproductions of photographs enhance and clarify the text. This is a really valuable contribution to surgical literature and is recommended to all interested in surgery.

Landolt's Lehrbuch der Physiologie des Menschen mit besonderer Berücksichtigung der praktischen Medizin Bearbeitet von Dr. med. Dr. phil. h. c. R. Rosemann o. ö. Professor der Physiologie und Direktor des physiologischen Instituts der Westfälischen Wilhelms-Universität zu Münster Twenty first edition. Paper Price 18 marks Pp 858 with 172 illustrations Berlin and Vienna Urban & Schwarzenberg 1935

Written essentially for medical students and practitioners of medicine, the book presents chiefly the well established facts of physiology. Theoretical discussions are not emphasized. Readers interested in theory and detail will find an unusually extensive bibliography at the end of each section. Numerous references are made to pathologic physiology. Most sections furthermore, end with a short historical sketch on the rise of our knowledge of the subject matter just dealt with. Fundamental aspects of biochemistry are not omitted. This single volume textbook of physiology continues to be, in spite of several shortcomings (e. g., endocrines) the best treatise on the subject in either the German or the English language.

Kurzgefasstes Lehrbuch der Psychiatrie Von Dr. Johannes Lange o. Professor der Psychiatrie in Breslau. Paper Price 7.20 marks Pp 254 Leipzig Georg Thieme 1935

Professor Lange, who was long associated with Kraepelin and who is responsible for the last edition of Kraepelin's handbuch, has succumbed to the urge of writing a compendium of psychiatry. The views expressed are essentially those of Kraepelin and the book contains a fairly good description of most of the mental disorders. There is nothing new that is taken up and the dynamic psychologic point of view is inadequately represented. There seems hardly any justification for the appearance of this volume at the present time, as there are a number of other volumes of identical scope already available.

Experimental Physiology By Sir Edward Sharpey Schafer F.R.S. Fifth edition revised by the author with the co-operation of W. A. Bain Ph.D. Lecturer in Experimental Physiology in the University of Edinburgh Cloth Price \$2.20 Pp 168 with 84 illustrations New York London & Toronto Longmans Green & Company 1934

Judging by American standards, it was concluded, after first perusal, that this laboratory manual in experimental physiology was prepared by the late Sir Edward Sharpey Schafer for college students for in the preface occurs no statement for whom the book was prepared. On the paper cover, however, appears a statement that "the new matter is of special significance for medical students, for whom the work is primarily intended." The book is quite too elementary for the students of most grade A medical schools of this country, however, it contains a number of diagrams that instructors of high school or college-physiology might find useful in presenting experimental methods and the principles of physiologic apparatus to their pupils.

Miscellany

STATUS OF ALLERGY TEACHING AS INDICATED IN MEDICAL SCHOOL ANNOUNCEMENTS

I HARRISON TUMPEER, M.D.
CHICAGO

This review concerns itself solely with the allergy matter published in the current medical school announcements. The apparent nonchalant assignment of allergy in medical courses aroused interest in the subject. Catalogues were solicited from all the medical colleges named in the Educational Number of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION of Aug. 25, 1934. Announcements were received from seventy-nine of eighty-six colleges. There was no opportunity to review the curriculums of seven schools (table 1). Allergy was not mentioned in sixty catalogues (table 2) and was listed in nineteen announcements, or 24 per cent of those which were received (table 3).

In only one school, namely, Yale University, is allergy entirely the province of pediatrics. At the University of Rochester there is a course in pediatric allergy conducted by my former associate, Dr. Jerome Glaser, as well as a course in the department of medicine. In addition to a required course

Total, 7	

in the department of medicine at the University of Michigan, an elective sensitization clinic is conducted at the University Hospital by members of the pediatric department. Although classified under the department of medicine at the University of Oregon, its course is conducted at a children's hospital. Columbia University offers a clinical clerkship in allergy in the department of dermatology as well as a section in the department of medicine. The catalogue of the New York Homeopathic Medical College and Flower Hospital mentions an arthritis and allergy department at the hospital but does not describe courses in the medical school. At Stanford University the study of allergic reactions is included in an elective course in immunology, apparently in the second year. At Duke University allergy has the standing of a specialty, equivalent to syphilis, urology and orthopedics. Altogether, four allergy courses are in some way bound up with pediatrics, one is associated with dermatology, one is represented by a hospital department, one is mentioned in immunology, and one has the rating of a specialty. The remaining eleven are entirely sub-heads of medicine. The subject is offered naturally in the clinical period, mostly in the fourth year. The number of students who have access to these courses varies from a few to the entire class. About one third of the courses are required. In some instances the required or elective status was not emphasized. The amount of time varies as nearly as can be determined from about four to sixteen hours. The rank of the instructors varies from lecturers to professors.

Read before the Chicago Society of Allergy, May 20, 1935.
From the Children's Allergy Section, Mandel Clinic of Michael Reese Hospital, aided by the Jessie Werthamer Fund.

The data obtained are of necessity a statement of the minimum attention that is paid to allergy in the medical schools. It is acknowledged that many medical school catalogues are slow to change their contents in keeping with the courses. This is particularly true of a subject such as allergy. Many schools are groping experimentally in their efforts to place the subject in the curriculum. Division of the subject into lectures and clinics is changing too fast for the catalogues to indicate. It may be assumed that more medical schools than the nineteen mentioned must be devoting some time to the subject, whether in the departments of internal medicine, pediatrics, dermatology, otolaryngology, immunology or others, without

actually listing the subject. In some announcements the descriptions of courses are brief and probably include allergy without so stating.

The relative recognition of this latest "specialty" was determined by contrasting the number of allergy courses with the number of such other medical subdivisions as cardiovascular disease, gastro-intestinal disorders, endocrinology and metabolism (table 4). A comparison of the number of schools mentioning these five subdivisions to the total number of announcements received gives the percentage of mention of these courses. These results are tabulated in the third column. The ratio of the mention of allergy to the mention of each of the other medical subdivisions is expressed in the last column and is termed the index of allergy recognition. A glance at these relationships shows that the four other subdivisions are

mentioned in 89 per cent or more of the catalogues, while allergy rates 24 per cent. It is readily understood that the index of allergy must approximate a constant. In this case the index of allergy is about 25 per cent. This means that the allergy discrepancy is real, since the other groups receive equal and almost unanimous recognition in the field of undergraduate medical teaching.

that the purpose of a course in allergy should be to acquaint the student with its manifestations, to give him some idea of how the specific etiology is determined, and to acquaint him with methods and treatment not only including specific inoculations but also the general care of the patient, his environment and his diet. The outpatient department should furnish patients to be used as texts and demonstrations before the class.

COMMENT

The status of allergy as it manifests itself throughout the country appears to indicate that the emphasis on the teaching of this subject is largely the product of the personality of that faculty member pursuing allergy as a specialty or as an adjunct to his clinical armamentarium. In line with this phenomenon the courses vary in scope and in intensity. It is not my intent in this review to suggest how allergy should be taught. Nevertheless it must be stated that the teaching of allergy in a busy outpatient clinic is usually unsuccessful because the urgent press of work leaves little time to devote to students. It would seem

SUMMARY

1 This review concerns itself solely with the scope of the published statements concerning allergy courses in the current medical school announcements.

2 It is conceded that more attention is probably paid to allergy than is indicated in these publications.

3 This analysis may stimulate allergists engaged in medical teaching to add or revise the statements published in their medical school announcements. Revision will complete the facts and will give a more accurate status to undergraduate instruction in allergy.

4 The varied nomenclature and descriptions of courses that were typically observed in the study of the allergy group prompts the suggestion that the association of medical schools take under advisement the feasibility of standardizing the descriptions of all courses so that the following facts may become uniformly available the department under which the course operates, the year in which the course is offered, the amount of credit, elective or required, size of class, total hours

TABLE 4—The Index of Allergy Recognition

Subjects	Total Mentions	Percentage of Mention	Allergic Index per Cent
Allergy	19	24

devoted, and rank of instructor. Other data naturally will vary with the school, i. e., more complete description of the courses, hours and days of the week, and location of the classroom.

5 A supplemental study may well be undertaken by the questionnaire method to fill in the details omitted from the catalogues.

6 The present review fulfils its fundamental purpose in portraying the present status of undergraduate allergy teaching as indicated in the current medical school announcements.

Malpractice Compensation Award as Bar to Malpractice Action—During the course of his employment, the worker sustained simple fractures of the radius and humerus of the right arm. Allegedly because of the negligence of his attending physician and of the hospital wherein he had been confined, the fractures did not heal and it was necessary to amputate the arm approximately six inches below the shoulder socket. The Oklahoma industrial commission awarded him compensation for the total loss of his right arm. Thereafter he brought suit against the physician and the hospital. He contended that he was entitled to maintain this action, not for the physical injury caused him through the negligence and unskilfulness of the defendants, which he admitted was barred by the award of the industrial commission, but for physical pain and mental suffering caused by the negligence of the defendants, since the workmen's compensation act makes no provision for an award for physical pain and mental suffering. There was a judgment for the defendants, and the plaintiff appealed to the Supreme Court of Oklahoma.

The question presented, said the Supreme Court of Oklahoma, has been definitely settled heretofore by this court. A worker is entitled to receive compensation through the industrial commission for an injury sustained in the course of his employment. The award includes compensation for the original injury and for the ultimate results of such injury, including the carelessness or negligence of the physician or hospital selected by the employer. Under the workmen's compensation act of Oklahoma, also, the award is based in part on suffering and mental anguish of the injured workman. There is but one exception to be noted among the Oklahoma decisions. In *Walker v Von Wedel*, 108 Okla. 292, 237 P. 86, the court allowed a recovery by an injured workman against the physician after an award had been made by the industrial commission and accepted by the workman, but in that case the workman charged that the acts of the physicians were "maliciously performed in an unskilful manner, which resulted in the unnecessary bodily suffering and mental anguish." In this case, however, there is no charge of maliciousness or wantonness, but the plaintiff predicated his case solely on negligence.

The court accordingly affirmed the judgment in favor of the defendants—*Alexander v Von Wedel* (Okla.), 37 P. (2d) 252.

Workmen's Compensation Acts "Malingering" Defined.—In the course of his employment, the worker was standing on a dump car loaded with beets. When the trap door at the bottom of the car was opened he fell to the bottom, landing astride an iron beam, with his right leg caught and doubled back in a jackknife position, and with about four feet of beets, weighing several tons, on top of him. His principal injury consisted of two broken vertebrae. He was hospitalized for several weeks and was fitted with a steel brace to hold his spine rigid, which he wore for about ten months. Thereafter he used crutches. According to his testimony, any twist or jar gave him intense pain, he could not stand on his feet and stoop forward, and he spent about half the time in bed. The compensation commissioner awarded him compensation for total and permanent disability and the award was affirmed by the district court, Scotts Bluff County. The employer then appealed to the Supreme Court of Nebraska.

The employer contended that the worker was a malingerer. Malingering, said the Supreme Court, as applied to compensation cases, may be defined as a deception by feigning, inducing, or prolonging either sickness or injury so as to secure undeserved compensation. In this case, roentgenograms clearly indicated that there was an injury to two vertebrae following the accident. Medical witnesses, called by the employer, testified that the worker was a malingerer and that at the time of the trial he was free from any pain. The worker flatly denied the charge. Since the accident, continued the court, the worker had done no work, had spent a great deal of time in bed, was hardly able to hobble about on crutches, and acted as if he were suffering pain. The trial court observed the workman move about the court room, observed his demeanor under examination, was enabled to detect his reaction, if any, to the charge that he was a malingerer, and could weigh the credibility of the neighbors and relatives as they testified to his everyday conduct in respect to his injury. The trial court rejected the opinion of the medical experts that he was a malingerer, and the Supreme Court found nothing in the record to justify interference with that finding. Judgment in favor of the worker was therefore affirmed—*Great Western Sugar Co v Hewitt* (Neb) 257 N. W. 61.

Wisconsin State Medical Society of Milwaukee, Sept. 17-20. Mr. J. G. Crownhart, 119 East Washington Avenue, Madison, Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to *THE JOURNAL* in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

- Reticulo-Endothel. Its Status in Certain Psychoses. G M Davidson Ward's Island N Y.—p 1433

Effects of Estrogenic Preparations in Idiopathic Epilepsy.—Whitehead and McNeil treated eighteen cases of epilepsy with different estrogenic substances. The usual dosage of one estrogenic substance given was fifteen drops three times a day, orally administered. Dosages as high as sixty drops were tried in some cases with no apparent difference in effect. Some of the patients were carried on a dosage of ten drops twice daily. Another estrogenic substance was given subcutaneously, usually from 1 to 2 cc. three times a week for the week preceding and the week following menstruation. One estrogenic substance was given orally one capsule twice daily for five days starting two days prior to the expected menstrual period. Some of the patients were allowed to take small doses of phenobarbital in addition to the hormone therapy. Marked relief occurred in eight female patients. Partial benefit was obtained in five other patients three of whom were males. Two female and one male patient failed to respond. The author also treated twelve patients who had migraine (eleven females and one male) with estrogenic substance. Six female patients had marked relief and three had partial relief. Of the eleven female patients all but two showed a definite relationship of the attacks to the menses. Several of the patients had polyuria, some noticed an increase in weight, and a number reported an increased feeling of well being. Two patients reported partial relief from symptoms usually associated with the climacteric. The possible rationale of the treatment is discussed. Alteration in the water balance produced by the autacoids used appears to be the most likely mechanism by which they were effective. The change that occurs normally at menstruation in the blood cholesterol might favor the development of seizures in the epileptic patient at menstruation especially if that individual also had a tendency to develop

an elevated blood lecithin. The fact that ovarian deficiency is accompanied by lowered blood calcium suggests a possible relationship between the latter and convulsive seizures. The authors feel that their results warrant further investigation in this field.

Blood Glutathione Level in Mental Diseases.—Brice states that there appears to be a statistically highly significant difference in the blood glutathione level between groups of mental patients and adequate individuals. This difference is greatest in catatonic dementia praecox. It is also marked in hebephrenic and paranoid forms of dementia praecox, and in dementia paralytica. It is less marked but still statistically significant in manic-depressive psychosis. In the small number of cases of epilepsy examined it was not statistically significant. Diurnal variation and exercise have been ruled out as influences affecting the validity of conclusions based on the data accumulated in this study.

Effect of Fundusctomy on Gastric Acidity.—Watson produced experimentally gastric and duodenal fistulas in five dogs. The duodenal fistula was placed on the anterior surface of the second portion of the duodenum at the level of the head of the pancreas, while the gastric fistula was placed on the anterior surface of the stomach in the region of the antrum or high on the cardia. Two series of control experiments were done. The dogs were made to fast eighteen hours. The maximal response in gastric acidity as well as changes in the hydrogen ion concentration of the duodenal content were noted in all five animals after the feeding of 100 Gm of raw meat and after subcutaneous injection of 1 mg of histamine. Aspirations of the gastric and duodenal content were made every hour in the experiments in which a meat meal was used and every fifteen minutes in the experiments in which histamine was used, and aspirations at these intervals were continued until the readings had returned to approximately the value during fasting. A sufficient amount of gastric content was aspirated each time to permit the determination of values for free acid and for total acidity. Titrations were run against tenth-normal sodium hydroxide, with Töpfer's reagent and phenolphthalein as indicators. Each experiment was repeated a sufficient number of times to determine the normal range of reaction. The emptying time of the stomach of each animal was determined with 250 cc of a 20 per cent mixture of barium sulphate in water and observations under the fluoroscope at intervals until the stomach was empty. After a reliable set of results had been obtained in the control experiments, a second operation was performed in which most of the greater curvature of the stomach and varying amounts of the fundus ranging from one half to four fifths of the total fundus were resected. The cardia, antrum and lesser curvature were left intact. The experiments with the meat and with histamine were repeated from two to seven weeks and from fifteen to eighteen weeks after the operation, and the results were compared with those obtained in the control experiments. Alterations in gastric acidity as determined by changes in the hydrogen ion concentration were very slight, while alterations in the hydrogen ion concentration of duodenal content were

rarely seen. Definite reductions in both concentration of free acid and total acidity were noted immediately after operation in those dogs in which extensive resection was performed, but in subsequent observations at the end of four months the changes were less marked.

Study of Disruptions of Abdominal Wounds—Milbert studied a series of 1,560 laparotomies in an effort to arrive at a clearer understanding of the mechanism of the production of disruption in abdominal wounds. He dwells on the broader aspects of the problem, elaborating on the phases of the healing of wounds, the usage and fate of catgut and a consideration of intra-abdominal variations in pressure. Too little consideration has been given to the study of intra-abdominal pressure. Most cases of disruption of abdominal wounds represent a failure of the suture line to hold, whether this is due to the suture material or to abuse, in the face of undue intra-abdominal pressure. Without the added factor of excessive abdominal pressure, many inherently weak wounds may escape disruption. The solution lies in the minimizing of the disruptive forces and in the more prevalent use of nonabsorbable, removable sutures, the effect of which is to tide a healing wound over its early period of weakness. The author does not attribute any etiologic importance to age, sex, seasonal incidence, primary illness or allergic phenomena. He believes that the newly awakened interest in the subject will lead to a reevaluation of the present accepted methods of the closure of wounds and to a closer scrutiny of the efficacy of absorbable suture material and of the surgeon's security in using it in the closure of a laparotomy wound.

The Blood Lead in Clinical Lead Poisoning—Blumberg and Scott studied the plasma cell partition of blood lead in eighteen cases of clinical lead poisoning by spectrographic analyses of the separated fractions from oxalated, citrated and heparinized samples, as well as by analyses of serum and clot. The results showed that by far the greater part (usually about 90 per cent) of the lead appeared to be carried by the cells or clot. Analyses of control bloods, including a hemophilic sample, indicated that the cell fraction contained at least half, and usually much more, of the trace of nonpathologic blood lead. Washing the cells twice with an isotonic solution of sodium chloride failed to remove appreciable quantities of the lead, thus demonstrating that the lead and the red cells were in comparatively firm combination.

Thyroidectomy for Endemic Goiter—Baughman believes that the symptoms, diagnosis and treatment of simple colloid goiter and exophthalmic goiter are generally known and agreed on. The surgical removal of the toxic adenoma is somewhat hazardous because patients usually wait until serious cardiovascular damage has taken place. Endemic goiter without an elevated basal metabolic rate or other signs of hyperthyroidism presents definite symptoms, namely, palpitation, dyspnea, nervousness, a sense of pressure, loss of weight, muscular weakness and irritability. All manner of cardiac abnormalities may be present with a normal basal metabolic rate. They are constantly present and to a more marked degree in the toxic adenoma. Myxedema is practically never associated with endemic goiter and rarely occurs after thyroidectomy for this type of goiter. This is shown by a comparison of metabolic rates taken before and after operation. The nontoxic adenoma should not be removed before the age of 21 unless there are definite signs of malignancy because of the possibility of recurrence. The nontoxic adenoma should be removed because of the certain development of cardiovascular damage later in life and because of the possibility of malignant degeneration, which occurs in about 6 per cent of goiters irrespective of the age of the patient. It should also be removed for the relief of pressure symptoms. A small single adenoma may be resected, but in multiple adenomas or uniform enlargement of both lobes a bilateral subtotal resection should be done.

Primary Carcinoma of Lung—Neely studied eighty case histories in which primary carcinoma of the lung occurred over a period of twenty-one years. He attempted to correlate the pathologic observations with the clinical data and to ascertain whether or not any conclusions could be drawn concerning prognosis. He found that the increased incidence of primary carcinoma of the lung is more apparent than real. The only proved source of origin of primary carcinoma of the lung is the bronchial mucous membrane. Primary carcinoma of the lung affects males only slightly more than females, and the age incidence corresponds with that of carcinoma in general. No more is known about the etiology of primary carcinoma of the lung than is known about carcinoma in general. Pulmonary carcinoma is found in the two lungs with about equal frequency. Distant metastases occurred in twenty-seven of the eighty cases reported and bore no relation to a gross or microscopic type of tumor. The basal cells of the bronchial mucosa are probably the cells from which all carcinomas of the lung arise. Metaplasia of the bronchial mucous membrane is found in all types of carcinoma and is not necessarily a forerunner of squamous cell carcinoma. Primary sarcoma of the lung probably does not exist. If it does exist, it must be extremely rare. Small cell or anaplastic carcinoma of the lung shows a marked tendency to involvement of the mediastinum. Primary mediastinal tumors other than lymphosarcoma, malignant thymoma and the lymphoblastoma group are secondary small cell carcinomas originating in the lung or some other distant focus. The round cell sarcomas or the oat cell tumors are included in this group. Massive mediastinal involvement and other secondary lesions may arise from a small and obscure primary focus in the lung. Of thirty-nine cases showing mediastinal involvement, nineteen were small cell carcinomas. Metastatic lesions in primary carcinoma of the lung may be the cause for the presenting symptom without pulmonary symptoms in many cases. Most endotheliomas of the pleura are in reality primary carcinomas of the lung with pleural involvement.

Mechanism of Internal Hydrocephalus in Spina Bifida—Russell and Donald examined ten cases of lumbosacral or dorsolumbosacral meningocele. In all a remarkable malformation of the hindbrain was observed. In this a tongue of variable length, consisting of cerebellar tissue and the greatly elongated medulla oblongata protrudes downward into the spinal canal. It overlaps and compresses the upper segments of the cervical cord, distending the dural theca in this neighborhood and filling the foramen magnum. The cavity of the fourth ventricle extends caudad into this tongue, lying between the cerebellar and medullary components. The maximal diameter of the ventricle is usually within the vertebral canal at and below the level of the foramen magnum, and here too or at a still lower level are found the choroid plexuses and the foramina with which they are associated. The plexuses are sometimes united into one mass, which lies in the middle line in the ventricular cavity. The floor of the ventricle presents the characteristic markings of the rhomboid fossa, and in the middle line toward its caudal extremity is a minute pore, which provides a horizontal communication between the ventricle and the central canal of the ventrally placed spinal cord. Cross sections of the brain axis show a somewhat complicated pattern according to the number of structures involved. Other structural abnormalities are commonly found in association with this malformation. The spinal cord appears abnormally small and the cervical roots always run in a cephalic direction to reach their exits through the dura mater. Their cephalic direction decreases as successive segments are examined until, in the upper thoracic region they are either horizontally or caudally inclined. Hydromyelia is present in a number of consecutive segments in the cervical and thoracic cord. There is a conspicuous hypoplasia of the cerebellum, which is usually composed of a small compact mass lacking differentiation into vermis and lateral lobes. The pons as well as the medulla oblongata is elongated and lacks the characteristic ventral protuberance. The cranial nerve roots arising from the pons and medulla are greatly elongated. This curious malformation was noticed first by Arnold (1894) in a case of spina bifida and was more fully described in the following year by Chiari in a series of seven cases of spina bifida, only one of which was an example of meningocele. A good description in five cases of meningocele was published by Solovtsoff (1901) but perhaps the best and fullest account is that of Gredig and Schwalbe in four cases of meningocele (1907). This lesion is called the Arnold-Chiari malformation. The authors believe that occlusion of the foramen magnum in cases of spina bifida will lead to a damming back of cerebrospinal fluid in the ventricular system and to internal hydrocephalus. It has for long been known that operative removal of the sac in spina bifida is frequently followed by hydrocephalus when this was not present before the operation. The development of hydrocephalus after operative removal of the sac can be simply explained as a decompensatory effect.

The extra absorbing apparatus provided by the sac may be just sufficient to balance the degree of obstruction at the foramen magnum in instances in which such obstruction is not severe. If this is true, operative removal of the sac will disturb this balance and will be followed by the development of internal hydrocephalus. The authors describe a comparable but far less pronounced malformation of the medulla oblongata in a case of lumbosacral meningocele without hydrocephalus. In conclusion, they suggest that a more typical Arnold-Chiari malformation may be the cause of the hydrocephalus that complicates some examples of meningocele.

- Carcinosarcoma Study of Microscopic Anatomy and Meaning of Peculiar Cancer W F Harvey and T D Hamilton—p 337

Carcinosarcoma—Harvey and Hamilton refer to their six cases of carcinosarcoma, which they define as a double tumor that is a mixture of carcinoma and sarcoma. Their most important example of carcinosarcoma was a tumor of the hypopharynx probably of esophageal origin. It consisted of a squamous cell carcinoma placed low down and arising from the esophagus or the larynx. Above this and continuous with the stroma of the epithelial tumor was a sarcomatous connective tissue containing one or two islands of solid alveolar, malignant squamous epithelium. At the summit the tumor was without epithelial elements and wholly sarcomatous. The authors believe that the sarcomatous element is a subsequent development to the carcinoma. The sarcomatous development is probably an exaggeration of stroma reaction to invasion by carcinoma. There are tumors both of epidermic and of glandular carcinoma type which may show aggregations of spindle shaped epithelial cells with much of the appearance of sarcoma and which may be called spurious carcinosarcoma or carcinoma sarcomatoides. A fibroblastic reaction is not uncommon in primary and secondary carcinoma, which may be very active without being malignant, it may pass over to malignancy and so constitute a carcinosarcoma. It is this transformation of stroma which the authors contend may occur in the case of some carcinomas and is to be separated from granulation tissue and spindle cell carcinoma. The possibility of a predisposition to overgrowth of stroma is one to be considered.

Treatment of Pulmonary Abscess N N Stoichitzka—p 1008

Treatment of Pulmonary Abscess—Stoichitzka discusses the medical and surgical methods employed in handling pulmonary abscess. The medical ones are divided into two groups, the true employment of medicaments and the so-called mechanical methods. He has used emetine in twenty-two cases with sixteen failures, three slight improvements and three recoveries. He is therefore far from enthusiastic over this method of treatment. Alcohol intravenously was employed in ten cases with six failures, two slight improvements and two recoveries. Autovaccines have produced only failures and was abandoned in favor of autopyovaccines, which gave two failures, two slight improvements and one recovery. The treatment by medical means, called mechanical, consists of postural drainage, bronchoscopic drainage or drainage by simple expression, the latter being obtained by artificial pneumothorax. By none of those methods were the results materially better than in a group of ten cases treated purely symptomatically. The most important surgical treatment of lung abscess is by phrenicectomy. This was performed on ten of their patients with three failures, four slight improvements and three recoveries. Pneumotomy was done in five cases, with four deaths and one recovery. Although the surgical results were mediocre, it must be emphasized that they were dealing with chronic abscesses which are almost universally considered less favorable for surgery. There is not yet any treatment definitely superior to the symptomatic.

Treatment of Nasal Fractures J Pouli—p 638
Chronic Boldine Poisoning in Human Subjects F Mainzer—p 639

Treatment of Nasal Fractures—According to Poult, the reposition of the fractures of the nasal cartilage can be accomplished readily by pressure with the fingers from both sides and if necessary, with simultaneous hook traction that has its point of attack in the concavities of the anterior portion of the nose. The traction is accomplished best with a blunt double hook that has an inner span of from 5 to 10 mm. The tips of the hook should be padded with cotton. If a fracture of the bony portions of the nose has to be reduced, a wide arterial forceps that is kept closed can be introduced along the nasal floor until the fracture has been reached. The eventually overlapping fragments are then loosened by traction with the double hook. If the vomer also is fractured, it can usually be replaced by traction. Finally, the depression can be lifted from the inside either by opening the forceps or by pressing the closed forceps flat against the depression. In order to retain the fragments in the proper position, the author employs an intranasal support that is made of glass and has the form of a triangle (musical instrument). To guard against asymmetry of the nose, he inserted the support into both nasal cavities, regardless of whether both were injured or not. The nasal support consists of a thick walled glass tube with an external diameter of 5 mm. Each side of the triangle is about 3 cm in length and the middle piece measures about 1.33 cm. The inner distance between the two ends is about 3 mm. It is advisable to have a hole in one of the arms of the triangle and to lead a string through this and the tubal opening and knot it above the upper lip, so as to prevent the triangle from slipping backward. The author states that this supporting apparatus was well tolerated by the patients. It was worn for from eight to fourteen days. It permits the discharge of the secretions and in some instances even limited nasal breathing. The author thinks that unless irrigation seems absolutely necessary it may be omitted, for, with the glass support, danger of stasis of the secretion is not great.

Bismuth Treatment in Acute Angina Silva Guimarães—p. 587

Bargehr Skin Reaction in Leprosy—Cerqueira Pereira points out that, while children ranging in age from 6 months to 3 years do not give a skin reaction to lepromin, they are susceptible to the infection. Repeated inoculations, however, in small children and adults will give positive results. The intensity of the skin reaction runs parallel to the number of inoculations. Bacilliferous lepers, during the evolution of the disease, may give positive results to the Bargehr skin reaction. The negative results of the test are probably due to the presence of antibodies that develop from a contact of the individual on whom the test is made with lepers. The presence of antibodies in the blood of persons who give positive results with the Bargehr reaction is proved by the positive results obtained in the same persons by the tests of Gomes and Rubino for leprosy. The positive result of the test in persons who have contact with lepers but who do not show any symptoms of leprosy is the manifestation of the presence of allergy and probably of an index of immunity. Therefore, until positive results are obtained with lepromin repeated inoculations are advisable.

Postoperative Development of Omental Tumors K. Strauss—p. 1108
*Prophylaxis of Postoperative Disturbances in Circulation S. Rusznayk, S. Karády and D. Szabó—p. 1111

Postoperative Development of Omental Tumors—Strauss describes a tumor of the omentum that developed after several abdominal operations. The tumor had grown to fist size within a year. Clinical peculiarities and the rather rapid growth made malignancy seem likely. The tumor was removed and the subsequent histologic examination disclosed a benign, inflammatory tumor of the omentum the pathogenesis of which could be explained by the preceding operation. The author reviews the literature on postoperative omental tumors giving especial attention to the type of operation after which they are most frequent, to the length of time that elapses after the operation before they develop, to the rapidity of the development to the histologic structure and to the erroneous diagnoses to which they may give rise. He gives a detailed report of the patient's history, describes the surgical specimen and discusses the various possibilities of development. He thinks that in this case several factors were involved. He mentions hemorrhagic foci, foreign bodies (suture material) and inflammatory exudates. He thinks that inflammation is the essential causal factor in the development of these tumors. Their radical removal and the severing of all adhesions is necessary in order to counteract the severe clinical manifestations that may be caused by them.

Postoperative Disturbances of Circulation.—Rusznayk and his associates call attention to former reports (see also abstract in THE JOURNAL, June 30, 1934 p. 2241), in which they demonstrated that persons with various disturbances can be classified into distinct groups according to the manner in which their blood pressure reacts to an injection of histamine. They point particularly to the so-called second type, in which an injection of histamine produces a temporary decrease in the blood pressure followed by a considerable increase. Persons in whom this form of histamine reaction results have a predisposition for postoperative collapse. It was the authors' aim to overcome this predisposition. They found that two daily injections of from 0.5 to 1 mg. of histamine given several days in succession changes the histamine reaction and the collapse tendency at least for several days. Accordingly they commence, from eight to ten days before the operation with subcutaneous injections of from 0.5 to 1 mg. of histamine. These injections are given twice daily and are continued until the day of the operation. The authors state that they obtained favorable

results with this treatment, for even major surgical interventions were tolerated quite well after the patients who had a tendency to postoperative collapse had been given the prophylactic histamine injections.

*Changes in First Heart Sound in Transmission Disturbances A. de Chatel—p. 1004

Water Content of Plasma and of Erythrocytes—Jimenez Diaz and his collaborators studied the water content of the total blood, of the plasma and of the erythrocytes in fifteen healthy persons and sixty two patients. They found that the fluctuations in the water content of the entire blood are caused primarily by variations in the ratio of the plasma to the erythrocytes. They stress that the value obtained by determining the dry residue of the blood is inadequate and often misleading. They concede that the water content of the blood may be increased under certain pathologic conditions but that it cannot be decreased. They did not succeed in finding cases of true anhydremia, that is, inspissation of the blood. The water content of the erythrocytes seems to be dependent on three factors: their size, hemoglobin content and age. In healthy persons the water content of the total blood was found to be between 78 and 81 per cent, of the plasma between 90 and 92 per cent and of the erythrocytes between 65 and 68 per cent.

Changes in Heart Sounds—According to de Chatel, the physical factors that play a part in the production of the cardiac sounds are not fully understood as yet. The author describes a case in which it was possible to explain the abnormality of the systolic sound on the basis of the simultaneous recording of the cardiac sounds and the electrocardiogram. He says that the intensity of the first heart sound is influenced by the respiratory movements and by changes in the rhythm. However, changes in the systolic sound are observable also in transmission disturbances in which the electrocardiogram records changes in the length of the PQ interval. A review of the literature reveals that the intensity of the first heart sound decreases as the transmission time, that is, the PQ interval lengthens. The author says that this rule applies only to cases in which the mitral valves are free from pathologic changes. The patient whose history is reported came to the clinic with the symptoms of acute decompensation. The first electrocardiogram showed sinus rhythm and a myocardial lesion. On the seventh day following the onset of the digitalis therapy the pulse became arrhythmic and the electrocardiogram indicated an atrioventricular block of the ratio of 1:2. Auscultation disclosed at this time that the first heart sound was almost inaudible in every eighth or ninth pulse beat. It was now decided to register the cardiac sounds together with the electrocardiogram. This record revealed that there was not a regular 1:2 block and that a part of the regularly blocked auricular contractions were transmitted with a considerably prolonged transmission time. In this manner there developed in the otherwise regular rhythm an arrhythmia of short duration. The sound record shows plainly that the first sounds that have the essentially smaller deflection correspond to the ventricular beats with the longer transmission time. This tallies with the auscultatory observations. The author explains that the patient had 'frustrated contractions' in which, paradoxically, not the pulse beat was lacking but rather the systolic heart sound. This case proves that the contraction of the auricles plays an important part in the development of the first heart sound in that the systolic sound becomes weaker as the transmission time lengthens, that is, the later ventricular systole follows after the auricular systole. The author shows further that in case of valvular lesions the changes in the cardiac sounds are not uniform.

- Congenital Skin Defects of Neck B. Smekó—p. 1653

Pressure in Cutaneous Vessels in Preeclampsia—Von Raisz endeavored to determine whether in women with preeclampsia there exists a symptom that indicates a threatening eclamptic attack with greater probability than the manifestations that were formerly considered in this connection, namely, the height of the blood pressure, the protein content of the urine, the severity of the edema and the patient's general condition. The author studied the pressure of the cutaneous vessels by means of Herzog's apparatus. In tests in 156 cases he made the following observations: 1. The pressure of the cutaneous vessels in healthy pregnant women is like that in nonpregnant women, 40 mm of mercury being the average and 50 mm the maximum. 2. The pressure of the cutaneous vessels of the women who have only pregnancy edema is less than normal, the greater the edema, the lower the pressure. 3. Even in apparently severe preeclamptic conditions, the pregnant or parturient woman remains free from eclamptic attacks if the pressure of the cutaneous vessels does not exceed 50 mm of mercury. 4. High pressure in the cutaneous vessels indicates that an eclamptic attack is threatening. Whenever the pressure exceeds 60 mm of mercury, eclampsia is practically certain but all measures designed to prevent an eclamptic attack should be taken even in cases in which the pressure exceeds 50 mm. The author reports thirteen cases. In a table he shows that edema, protein content and the height of the blood pressure would not have been sufficient to indicate threatening eclampsia but that the pressure of the cutaneous vessels gave a correct indication of the severity of the condition. The author points out that a quick termination of the delivery alone is not sufficient to prevent an eclamptic attack if the pressure in the cutaneous vessels is high. He stresses the value of venesection as a preventive measure. He thinks that it should be tried first and that the other medicinal and operative measures should be taken only if it does not reduce the abnormally high pressure in the cutaneous vessels.

Adrenal Cortex Extract in Treatment of Gestoses—A recent report by Stemmer about the use of adrenal cortex extract in the treatment of gestoses induced Torre Blanco and Riesgo del Campo to report an interesting case. The woman, aged 24, had had two normal deliveries, but in both pregnancies she had vomited during the first three months and during the second pregnancy the vomiting recurred three months before the delivery and persisted until two months after the delivery. When the patient came under the authors' observation, she was in her third pregnancy. She had attacks of vomiting, but she was more annoyed by pyrosis and acidity. She also had occasional attacks of vertigo. These symptoms disappeared and after that the pregnancy took a normal course until one month before expected delivery. At this time severe vomiting, pyrosis and hypersalivation set in and the general condition was poor. The breath smelled of acetone, and examination of the urine disclosed severe acetoneuria and the presence of albumin and of biliary pigments. The authors think that the disorders which developed at the end of pregnancy are due to a metabolic disorder, namely, acidosis, the chief cause of which is a deficient liver function and an irregular muscular metabolism, which in turn produces a disturbance in the production of the acetone bodies and a considerable increase in the lactic acid content of the blood. In this connection the authors call attention to the fact that a number of investigators detected a tendency to acidosis not only in the course of gestoses but also during pregnancy. Various factors are involved in the genesis of acidosis, but the increase in the lactic acid content of the blood, which is caused by an abnormal glycogen metabolism in the muscles and by a deficient lactic acid synthesis in

the liver, is the most important factor. Since it is known that the adrenal cortex influences the increased lactic acid content of the blood and since water retention, which may be increased by the cortex hormone, was absent, the authors resorted to treatment with adrenal cortex extract and administered three injections, which were well tolerated. The lactic acid content of the blood and the alkali reserve were examined during this time. The vomiting ceased on the first day the treatment was instituted, but the acetoneuria persisted. The treatment with adrenal cortex was discontinued and 30 units of insulin and 150 cc of dextrose were given. This treatment was continued for four days, being given twice on the first two days and once on the other two days. The acetoneuria disappeared as soon as insulin was given. Thus the authors succeeded in effecting a separation of the two chief factors of the acidosis, the excessive lactic acid formation in the blood and the formation of acetone bodies. The first of the two factors was counteracted by the adrenal cortex extract and the second by the insulin-dextrose treatment.

Svenska Läkaresällskapet's Handlingar, Stockholm

61: 63 180 1935

- *Studies on Undulant Fever in Sweden G. Olin—p. 63
- Suicide by Blows of Ax on Head Contribution to Discussion G. Hultqvist—p. 169

Undulant Fever in Sweden—Olin states that from 1929 to 1933 about 120 cases of undulant fever have occurred annually in Sweden. Of 565 patients, 65.2 per cent were men. Persons in the fourth decade of life were most often affected. A close relation between undulant fever and infectious abortion in cattle was noted. Serologic studies supported the assumption that latent abortive infection with *Bang's bacillus* occurs in man. Test of 288 persons without history of undulant fever and with little likelihood of exposure to infection gave positive cutaneous reactions in twenty-one, or 7.3 per cent, the reaction being more often positive in adults than in children and in women than in men. The cutaneous reaction was positive in six persons with a history of undulant fever from six months to six years previously and in nine bacteriologists who had been working with *Brucella* cultures for a longer time without having undulant fever. A marked phagocytosis was found in four of the six and in seven of the bacteriologists. Of 251 attempts at blood culture in undulant fever, 46.2 per cent were positive. Bacteria were more often demonstrable in a highly febrile stage but could occasionally be cultivated from the blood during afebrile periods. In seventy-five cases verified by blood cultures, the results show that agglutination in serum dilution is 1:320 and from 0 to 10 per cent hemolysin in complement fixation tests with 0.1 cc. of serum could be regarded as positive. The agglutination test seemed somewhat more reliable. In 171 cases of undulant fever there was a single fever period in one fifth, there were two or three fever periods in more than one half, and there were four or more fever periods in one fourth. The fever was usually high. The general condition was little affected. The pulse frequency was low in comparison to the temperature. Enlargement of the spleen was found in more than one third of the cases. The diazo reaction of the urine was positive in about one fourth of sixty-four cases. Leukemia appeared in most cases, the percentage of mononuclear elements was generally increased, and slight or moderately increased blood sedimentation was usual, the values generally being lower during the first stage than during the later course and higher during febrile than during afebrile periods. In the six fatal cases the cause of death was mainly pulmonary or circulatory complications. The duration of the disease till disappearance of the fever varied from eight to 532 days, the average duration being 91.5 days. The average convalescence lasted three months. Chemotherapy and vaccine treatment with subcutaneous injection of killed bacteria were both without effect.

CORRECTION

INFANT FEEDING

HISTORICAL BACKGROUND AND MODERN PRACTICE

GROVER F. POWERS, M.D.
NEW HAVEN, CONN.

The subject of infant feeding seems somewhat hackneyed in these sophisticated days and perhaps for that reason more than any other needs occasional appraisal and reorientation. Toward this accomplishment the following discussion is offered.

HISTORICAL SUMMARY

Appreciation of the present status of the practice of infant feeding requires a view, even if fleeting, of the historical background of the subject. Prior to relatively recent times the successful practice of infant feeding consisted almost entirely in the use of human milk either from the mother or from a wetnurse. Animal milks, broths, pap, honey and wine were the principal food substances used in hand feeding and rarely led to the development of a healthy child if they were the exclusive sources of nutriment, i.e. unless also some human milk was given the infant.

When was the scientific basis of the present structure established? Various students would probably give different dates, but it would seem sound to select the latter half of the eighteenth century, the period when inaccurate but thought-provoking chemical analyses of milk were first being made. Prior to this period, for example, breast milk was tested by the finger-nail technique—a test that was still advocated in 1752, more than 1,600 years after it was described by Soranus of Ephesus, who flourished from 98 to 117 A.D.¹ Michael Underwood, who lived from 1736 to 1820, wrote a splendid treatise on the diseases of children, which was first published in 1784 and passed through sixteen editions, but not until the fourth edition, that of 1799, was any mention made of the chemistry of milk, this marked a real beginning for the scientific approach to the subject of infant feeding by the clinician. Still² says that with Underwood "paediatrics in England had crossed the Rubicon: the modern study of disease in childhood had begun."

The span of time in which a scientific basis for infant feeding has been emerging is thus probably less than 150 years. During these years developments in various

fields of scientific and clinical inquiry have impinged on the subject, sometimes setting it off in one direction and sometimes in another but, taken together, establishing a sound body of knowledge and experience to guide the modern clinician.

It may be well to have at hand in outline form some of these scientific and clinical studies and stress their effect on infant feeding and on concepts of nutritional disorders.³

Chemical Studies—The beginnings of milk analyses have been referred to, but the far-reaching effects of research in physiologic chemistry, notably the chemical analyses of foodstuffs under Justus von Liebig (1803-1873) and others, were manifested in the analyses of milk by J. Franz Simon, a chemist (1807-1843), in 1838 and later, and by Philip Biedert, a pediatrician (1847-1916), in 1869 and later. On these and other chemical studies was based the conception of the harmfulness of various constituents of cow's milk and the many attempts to imitate human milk as exemplified in numerous milk mixtures, now practically obsolete, and in the various cream and top milk mixtures. The so-called percentage method of feeding had its genesis in the work of Biedert but was brought to fruition by Thomas Morgan Rotch (1849-1914) in this country in the eighteen nineties. As Rotch has pointed out, percentage feeding is rather a method of calculation than a method of feeding, no one can satisfactorily prescribe food for an infant who does not have knowledge of the composition of that food. The use of "simple dilutions" of milk with added carbohydrate does not ignore composition but simply does not stress the importance of slight variations in the concentration of the individual constituents. It is probable that the mathematical intricacies of the "percentage method" may have driven some lazy physicians to the use of patent baby foods, but such foods were widely used before the percentage system of calculation was born.

Pathologic Studies—The development of pathologic anatomy had its influence in the sphere of infant nutrition. One of the earlier workers in this field was the gifted French physician Charles-Michel Billard (1800-1832), who performed many autopsies on infants and attempted to classify disease according to the pathologic lesions. Other early attempts at classification of nutritional disorders "were made by the French pediatricians De Lord (1837) and Velhies (1838), who thought that the symptoms of vomiting and diarrhea were the result of an inflammatory condition of the digestive tract."⁴

Read before the Section on Pediatrics at the annual meeting of the Medical Society of the State of New York, May 14, 1935.

From the Department of Pediatrics, Yale University School of Medicine, and the Pediatric Service of the New Haven Hospital.

In Germany, Herman Widerhofer (1832-1901) was a leader in studies of this type, which sought to find at the autopsy table some basis for disturbances in nutrition. By and large, this method of approach, except in a negative way, has not greatly clarified the problems of feeding and nutrition, although, as will be shown later, a correlation of postmortem observations with bacteriologic studies finally solved the etiology of bloody diarrheas in infants. So long as "the fundamental concept of disease remained fast-rooted in the anatomical lesion, the theory of treatment conscientiously limited itself to a number of drugs designed to combat that lesion" (Heubner).

Bacteriologic Studies—The association of infant feeding with research in bacteriology has been close, and the contributions have been outstanding. Pioneer work in this field was done by Theodor Escherich (1857-1911) on the relationship of the colon bacillus to disease (1886). The most dramatic contribution was doubtless the demonstration by Duval and Bassett in 1902 at the Thomas Wilson Sanitarium in Baltimore that ileocolitis or bloody diarrhea in infants is really dysentery caused by an organism of the groups of bacilli described in part by Shiga in 1898 and by Flexner in 1900.

But infant feeding is perhaps under its heaviest debt to bacteriology for its gifts of pasteurization (begun first on a commercial scale in Denmark in 1890) and sterilization of milk and milk mixtures. By these means typhoid, dysentery, tuberculosis and streptococcal infections are specifically eliminated or reduced in incidence, and other infantile disorders of a nonspecific type have been controlled by the use of "clean" milk. For out of these early bacteriologic studies there emerged the campaign for "clean, pure milk," the establishment of Walker-Gordon Milk Laboratories (Boston, 1891), the introduction of certified milk by Coit of New Jersey in 1892, and the establishment of "consultations for nurslings" by Budin in Paris in 1892 and of "milk depots" by Variot in 1893 and Dufour in 1894.⁵ The young pediatrician of today little realizes how much modern pediatrics owes to these early movements, the baby milk station with its complicated "feeding formulae" has gone, but pasteurization, sterilization, tuberculin testing and the infant welfare conference remain.

Metabolism Studies—The fundamental work of Rubner set the stage for the great contributions of himself and Otto Heubner (1893-1926), who in 1894 built the first respiration calorimeter for infants. Heubner's contribution on the energy requirement of infants is basic to this day, along with similar studies by Benedict, Talbot, Fleming and Murlin. Without knowledge of the energy requirement of the infant, no scientific program for his feeding can be laid down, but there is no "caloric system of feeding" and, as Aldrich⁶ points out, the calory is "a unit of combustion not of nutrition." Practical use of calculations of the energy value of milk mixtures did not get under way until well after the turn of the century.

A pioneer in the study of the metabolism of the child was Wilhelm Camerer (1842-1910), who in 1894 published important observations on the subject based on extensive personal observations. Studies in the field of infant metabolism continue to have a most important place in pediatric research.

Clinical Studies—With a background now somewhat extensive, valuable clinical correlations were attempted. Most noteworthy were those of Czerny and Keller in 1906 and Finkelstein in 1910. The classification of nutritional disorders by Czerny was attempted on an etiologic basis and consisted in a correlation of certain nutritional disorders with "too much" of certain food substances such as starch, fat or protein. Finkelstein's classification was purely clinical, he also had the conception of the harmfulness of "too much" of certain food substances, but he believed in the relative benignity of casein and fat and was inclined to blame the sugar and whey proteins and salts. This concern with the harmfulness of "too much" of some food ingredient gave way during the development of knowledge of vitamins to a phobia of the results of "too little" of some of the same or other substances or elements of the diet.

Czerny and others developed the conception of the effect on the gastro-intestinal tract of infections not in that organ. Enteral infections, so prevalent in the pre-"clean milk" days, have become less and less common, but infections elsewhere than in the intestinal tract (parenteral infections) as causes of nutritional disorders have received ever increasing emphasis.

Vitamin Studies and the Concept of Food Deficiencies—Lunin in 1880 showed that a synthetic milk was not adequate for normal nutrition, and Eijkman in 1897 first produced experimentally a disease due to a vitamin deficiency—beriberi in pigeons. Since these studies, and particularly in the last twenty years, the contributions on the subject of vitamins have poured forth, important alike in number and content. But in addition, stimulated by the concept of disease resulting from absence of or "too little" of the vitamins, substances at that time unidentified, investigators became interested in ascertaining the effect of "too little" of many substances of known composition. Hence present day concepts of "too little" water and salts leading to shock and dehydration, "too little" protein to nutritional edema, "too little" iron to certain forms of anemia, "too little" of certain amino acids to stunting and death, "too little" calcium and phosphorus to skeletal defects, the illustrations might be extensively amplified. McCollum in 1932 stated that "there are at least thirty-seven individual substances essential for a complete diet. These consist of amino acids, linoleic acid, dextrose, minerals and vitamins." The figure would doubtless be raised today.

THE FORMULATION OF THE INFANT'S DIET IN MODERN PRACTICE

As the result of the knowledge of nutrition, which originated in diverse domains of science and in clinical observations and has been focused on the problems of infant feeding, the concept of the "balanced dietary" dominates the present era. It is largely to this aspect of modern infant feeding that I now invite attention—to the concept of the beneficence of "enough" of food constituents in contrast to that of the past of the harmfulness of "too much" or "too little." For the sake of completeness, most of the important items in the construction of the infant dietary will be mentioned, but only a few will be emphasized.

Energy Requirement—The normal infant tends to satisfy his total energy requirement whether the milk mixture is concentrated or dilute. This requirement for the individual baby seems relatively rigid, whereas the total water requirement is somewhat labile, as is

⁵ Holt, L. E. Infant Mortality Ancient and Modern. An Historical Sketch, Am. Assn. for Study and Prevention of Infant Mortality 4th annual meeting Washington D. C. 1913.
⁶ Aldrich, C. A. Science and Art in Child Nourishment. J. Pediat. 1:413 (Oct.) 1932.

evidenced, for example, by the fact that the water content of woman's milk is the same whether it nourishes children in the arctic or in the tropics. It would seem, then, that the physician in prescribing the infant's food should think first in terms of caloric requirement, it is one of the essential checks and balances in the determination of the dietary. Although the scientific measurement of the energy requirement of a relatively few infants has established the range to be between 90 and 125 calories per kilogram of body weight, in practice the reaction of the child to the calories given determines what additions or subtractions are to be made in a diet. In undernourished infants the estimation of caloric requirement is made on the basis of the weight to be expected if nutrition has been adequate. Earlier in the first year the infant requires more than later, the thin child and the active child require more than the fat, phlegmatic infant.

The Calory in the Assessment of Milk Mixtures—The calory is not only a measure of the total energy requirement of the infant but a unit by which mixtures may be satisfactorily assessed and compared.⁷ That is to say, a diet can be evaluated in terms of its total energy value and in the percentage of the total calories individually furnished by protein, carbohydrate and fat, the salt content can be expressed in terms of milligrams per calory, and so on with respect to the other ingredients of the food, whether they are amino or fatty acids, lactose, iron or iodine. Water content is thus related when caloric value per ounce or cubic centimeter is stated. Food appraisal on a gravimetric basis depends on the content of water and of various solid constituents of dissimilar qualities, the gram and the ounce have no meaning as units of nutritional currency. By contrast, the calory is a common measure of the energy yield of the total food and of the protein, carbohydrate and fat constituents separately as well. Furthermore, the calory is an independent unit of evaluation and has physiologic implications. The amount of food ingested when the supply is not limited is not determined fundamentally by the gastric capacity (as was so dogmatically taught for years) or by the bulk of protein, carbohydrate, fat, roughage and water but rather, in large measure, by the energy yield of the food to the body.

Since the appraisal of a diet seems most significantly done in terms of the calory, it seems logical to express the known facts of nutritional requirements of individual food components in the same terminology. Thus, for example, it is usually stated that the breast fed infant receives an adequate amount of protein at the level of from 1.5 to 2 Gm per kilogram of body weight, but this is possible only if the baby takes about 175 cc of milk (about 120 calories) per kilogram of body weight. If the infant should take less, it might seem to follow that the food was at fault, since the child will receive less than from 1.5 to 2 Gm of protein per kilogram. If, however, it is stated that the breast fed infant receives 8 per cent of his total calories, whatever their number, in protein, the important fact of the relationship of protein to other food constituents in the body is brought forward, the baby may

take little or take much, but the fact that is thereby emphasized is the character of his appetite, not a seeming deficiency in his food. As will be pointed out later in this paper, the number of calories ingested, except in the case of the sick, feeble or premature infant, can be safely left to the baby when the supply of milk is adequate.

Protein—The protein needs of the breast fed infant are apparently met when he receives in this food substance 8 per cent of his total calories. Since human milk protein is largely the complete protein, lactalbumin, and cow's milk contains a large amount of casein, which is not lacking but relatively low in an essential amino acid, cystine, it has been deemed advisable to give between 10 and 20 per cent of the total calories in protein when the source is cow's milk. This is from 3 to 6 Gm per kilogram of body weight and is usually met by giving the infant about 100 cc of milk per kilogram of body weight. But the minimum requirement of protein for the infant has not been determined. It has been taught in respect to the protein of cow's milk that a mixture in which 10 per cent of the total calories was in protein, 65 per cent in carbohydrates and 25 per cent in fat, i.e., ordinary sweetened condensed milk (developed by Borden in 1856), led to various nutritional disturbances, it was supposed that there was too little protein, too little fat and too much sugar. Dr. Harold Harrison of the department of pediatrics at Yale has just completed balance studies on five infants so fed and receiving cod liver oil and orange juice. It was demonstrated in these studies that the infants on this milk mixture showed as great a retention of nitrogen as they did when given an equal number of calories per kilogram of evaporated milk diluted so as to be equivalent to whole milk with 6 per cent of the mixture in added sugar, 15 per cent of the total calories yielded by this mixture was in protein. The retention of calcium and phosphorus was slightly lower in the babies on condensed milk than in those on the evaporated milk mixture but entirely adequate according to standards established by metabolic studies with breast milk. It is probable that the harmful effects of such milk mixtures in the past were due to excessive dilution and the lack of supplementary vitamins.

In a recent experimental study Smuts⁸ has shown that in adult animals of different species, widely variant in size, the endogenous catabolism regardless of species is closely related to the basal metabolism, so "that 2 mg of nitrogen are lost to the body daily for every calory of basal heat. This estimate of the endogenous loss of nitrogen is the basic information necessary to compute the maintenance requirement of protein." This important investigation is basic for certain calculations by which experimental data are brought to bear on the matter of protein minimum. These calculations, while they must be based ultimately on data obtained from growing animals and babies, suggest that the protein of human milk is very nearly minimal in amount for the normal infant. Experimental proof may be obtained in this way of the clinical judgment of certain pediatricians that premature infants do better on human milk when that diet is supplemented with cow's milk protein.

In respect to the protein of cow's milk, it is not sufficient that it be adequate in amount and quality, it

⁷ For example by determining the percentage of total calories in protein, carbohydrate and fat it can be shown that seemingly dissimilar mixtures such as condensed milk, one-third milk with 5 per cent added sugar and Schick's dubo (whole milk to which 17 per cent sugar has been added) have the same relative composition except for water content. Likewise the similarity in the pattern of caloric percentage distribution of protein, carbohydrate and fat in butter flour mixtures and S. M. A. to cream and top-milk mixtures and to human milk may be demonstrated —Powers (footnotes 17 and 18).

⁸ Smuts, D. B. The Relation Between the Basal Metabolism and the Endogenous Nitrogen Metabolism with Particular Reference to the Estimation of the Maintenance Requirement of Protein. *J. Nutrition* 9: 403 (April) 1935.

must be changed from its natural state. This process has been accomplished in a variety of ways. Budin⁹ showed that the cooking of cow's milk greatly enhanced the value of the milk in the feeding of infants.¹⁰ Similarly, investigators have fed milk which has been diluted, concentrated or dried, alkalinized, acidified, peptonized, treated with colloids by the addition of starch solution, acacia or gelatin,¹¹ with a growing realization that, however dissimilar some of these processes and however diverse the changes produced by them in the milk, one effect common to all is brought about such that when the milk is acted on by rennin the protein is precipitated in finer curds than is the case with raw milk. The degree of fineness varies with the particular method of denaturation used. It is believed that this change in the protein largely accounts for the favor which milk so modified has found in the feeding of infants.

Fat—From the standpoint of facility of caloric supply, it is desirable to have fat in the food. Why are fats otherwise desirable? The answer to this question is incomplete. The fats are associated with certain vitamins and previtamins, but these are now available in fat-free concentrates or other forms. During the great war, Pirquet observed many children who received little fat in their food. As the result of von Groer's experiments in Pirquet's clinic, it was believed that fat could be entirely eliminated from the diet. However, the infants von Groer studied can hardly be said to have done well. Burrs' work suggests that certain unsaturated fatty acids—linoleic and linolenic—are essential but interchangeable in the body economy. The fats are intimately associated with water, mineral, phospholipid and sterol metabolism. There is, therefore, suggestive evidence that, ordinarily, cow's milk should not be so modified for infants that fat is completely removed. On the other hand, clinical experience supports the belief that a large amount of butter fat is not handled well by most infants artificially fed and that about 20 to 30 per cent of the total calories (from 2 to 3.5 Gm per kilogram of body weight) in fat is an optimum amount.

Recent studies on fat metabolism in infants are of great importance. Holt, Tidwell, Kirk, Cross and Neale¹² have shown that the "size of the fat particles is without influence on fat absorption" and that "volatile fatty acids in amounts considerably larger than those present in butter appear to be harmless." Both of these observations are contrary to much previous teaching. Two further conclusions of Holt and his associates are of practical import. The first of these is that "a comparative study of various fats and fat mixtures indicates that those mixtures specially designed

for infant feeding are no better absorbed than butter. Certain animal and vegetable fats are, however, distinctly better absorbed." The other conclusion referred to is that "fat-poor diets tend to produce loose, fermentative stools", at times such diets "appear to bring out allergic manifestations" (eczema and spasmodic bronchitis).

Hansen¹³ has brought forward evidence that certain cases of eczema are favorably influenced by the addition of oils containing large amounts of unsaturated fatty acids (corn oil and linseed oil). Since these patients showed low values for the iodine number of the fatty acids of the blood serum and the low iodine numbers could be raised by administration of the oils referred to, Hansen ascribes the favorable effect to a greater need of these patients for certain unsaturated fatty acids.

Carbohydrates—In regard to carbohydrates, clinical experience has demonstrated that additional amounts should be added to the carbohydrate in the milk. Indeed, one observation seems very clear, namely, that if the protein, mineral and vitamin contents of the food are satisfactory the carbohydrate content may with safety reach proportions commonly practiced only by the use of sweetened condensed milk. The harmful effects of that food are now recognized to be due not to the high carbohydrate content per se but to lack of vitamins and, as often used, to excessive dilution.

Lactose, sucrose from cane, beet or banana, levulose in fruit juices and in honey, dextrose, maltose, dextrans and starches all have a greater or less place in infant feeding. Differences in cost, taste, digestibility, rates of absorption, osmotic pressure, and nutrient influence on bacteria are some of the points on which one should like exact data so that the optimal carbohydrate or combination of carbohydrates might be selected for the infant. Unfortunately, as Marriott points out, "there are few, if any, carefully controlled clinical observations on the intestinal tolerance to the various sugars and most of the statements made appear to be based only on general impressions."

Too much emphasis has been placed on the fact that the milk sugar of all animals is lactose. Since the sugar ultimately utilized by the body cells is dextrose, there could be no accumulation of that sugar in a secretion such as that of the mammary gland. But why lactose is excreted in milk rather than some other carbohydrate is not known. The question presents itself: Is there a minimal requirement for lactose? Pertinent data such as these may be given that lactose, because of prolonged acid fermentation, favors calcium absorption, and that a lactose derivative—galactose—enters into the structure of the glycolipins of nerve tissue. If milk is the basis of the infant's food, the lactose so given almost certainly meets the minimum requirements for that substance. The matter then becomes of importance only in the construction of milk-free foods for infants, a problem of growing interest to pediatricians.

The advantages of a mixture of added carbohydrates, when any but small amounts are used, probably rests on solid ground. Since a variety of enzymes are required for the digestion of a variety of carbohydrates, the absence or reduction in amount of any specific enzyme will likely be associated with less digestive disturbance if this food element is fed as a mixture of

9 Budin Pierre. The Nursing translated by William J. Maloney. London: Caxton Publishing Company 1907.

10 Soxhlet introduced the practice of cooking of milk in Germany in 1886 and Budin and Chavane in Paris in the eighteen nineties. When the practice actually began is not known. Bartholomaeus Metlinger (late fifteenth century) advocated the boiling of milk. He like many other writers, probably advocated the procedure because it was observed that raw milk was more laxative than boiled milk. After the development of bacteriology boiling was practiced to inhibit the growth of bacteria. It was not until the work of Brennemann (A Contribution to Our Knowledge of the Etiology and Nature of Hard Curds in Infants' Stools. *Am. J. Dis. Child.* 1: 341 [May] 1911. Boiled vs. Raw Milk. *An Experimental Study of Milk Coagulation in the Stomach.* *J. A. M. A.* 60: 575 [Feb. 22] 1913) and Ibrahim about 1911 that it was clearly recognized that boiling accomplished two distinct purposes: it made the milk more digestible and it freed it from living bacteria. I believe that all cow's milk used in feeding infants should be boiled or otherwise cooked to an equivalent degree.

11 An old procedure advocated by Underwood and the elder Meigs and by many others in recent years.

12 Holt L. E. Jr., Tidwell H. C., Kirk C. K., Cross Dorothea M. and Neale, Sarah. Studies in Fat Metabolism. I. Fat Absorption in Normal Infants. *J. Pediatr.* 6: 427 (April) 1935.

13 Hansen, A. E. Study of Iodine Number of Serum Fatty Acids in Infantile Eczema. *Proc. Soc. Exper. Biol. & Med.* 30: 1198 (June) 1933. Serum Lipid Changes and Therapeutic Effects of Various Oils in Infantile Eczema. *ibid.* 31: 160 (Nov.) 1933.

small amounts of several carbohydrates rather than as a large amount of a single sugar or starch. Moreover, under such circumstances the availability of the products for absorption is spaced, the varied influences on bacteria and yeast of different nutrients are achieved, and the hydragogic effect of the milieu is lessened. It is demonstrated by clinical experience that small amounts of starches, even in calorically valueless amounts, before the infant is 6 months of age, are desirable in the modification of milk, a finer curd and a more demulcent mixture, as well as other less tangible qualities, are achieved thereby.

Laxative effects are probably promoted by increasing the relative proportion of malt sugar over others, but it is important to recall in this connection that many of the commercial products containing maltose are mixtures not only of sugar and starch derivatives but of salts and other substances largely unidentified, which may well cause the laxative action.

It must be emphasized that dextrose is an essential requirement of the animal organism, the minimal amount "necessary for the maintenance of life and the prevention of ketosis is approximately 3 Gm per kilogram of body weight per day in the case of young infants"¹⁴. This amount is about 12 per cent of the total calories for infants. However, if sufficient calories are ingested, the proportion that can be given in fat is too small to bring about ketosis, the use of carbohydrate in large amounts in the infant's diet really rests on successful clinical experience.

Vitamins—In the various procedures concerned in the modification of milk it has been appreciated that the end product is comparatively poor in vitamins C and D and that the diet must be supplemented as a routine with respect to them. Most pediatricians believe that the A and the B complex are present in adequate amounts in milk. However, in respect to vitamin B, special consideration seems required in certain cases. Vitamin B is a fundamental necessity for metabolism. Cowgill has demonstrated that the requirement for this vitamin is directly proportional to the total metabolic rate, while a certain amount of the vitamin may be stored, starvation depletes the supply. Cowgill has also shown that the vitamin B requirement of dogs is generally increased when the animals are given large amounts of water. These facts may be pertinent in the case of infants who are convalescent from a severe diarrhea with dehydration and who have been starved and given large quantities of fluid. Vitamin B in some concentrated form may thus be a desirable addition to the diet of convalescent infants.

Of great concern to the pediatrician is the use of vitamin and salt fortified foods and the various vitamin and salt mixtures. Adequate data on the potency and effectiveness of most of these substances are lacking. Furthermore, physicians may well be concerned with the possible harmfulness of many of these well advertised preparations of vitamins, iron, copper, iodine and the like and the nullifying effect of one on the other. The public health aspect of this whole matter and its relation to food advertising is one that challenges the best thought of every physician and especially of those to whom authority and decision in such matters have been delegated.

Water—In infant feeding, water should be regarded in its true light, namely, as one of the essential struc-

tural elements of the body. Water is necessary also in the regulation of temperature and in the assimilation and elimination of metabolic products. Water has a value in promoting greater ease in the digestion of cow's milk, but it is misleading to think of this as the primary function of water, as is so often done in speaking of the dilution of milk mixtures.

The water requirement of the infant is greater than that of the adult, since the requirement is roughly proportional to the total energy metabolism, many other important factors are involved, such as external heat and humidity, muscular activity, and the salt and nitrogen content of the food. The breast fed infant receives from 125 to 150 cc of water per kilogram of body weight irrespective of many of these factors, this is the pediatrician's guide, but there must be a wide margin of safety in this quantity. Schoenthal¹⁵ found that in the artificially fed infant receiving from 35 to 60 cc of water per kilogram symptoms of acute dehydration developed, this suggests a minimum requirement of water for the artificially fed infant. Whether most of the water should be given with the milk mixture is to be determined in the individual case, but some water as a matter of habit training should be given alone between some feedings.

Salts—In practice the necessary inorganic material is adequately cared for if the amount of protein in the milk mixture is adequate. The exception is iron, which in the case of the premature infant may perhaps be augmented.

RULES FOR DEVISING FORMULAS

In developing the formulas by which satisfactory milk mixtures may be prepared, various conceptions and rules have obtained, the mixtures evolved will be shown (chart 1) to have many similarities regardless of the method by which their composition was determined.

Some of the bases of the formulations may be described.

1 The approach of Meigs, Biedert and Rotch. By various means, a milk mixture is devised that has approximately the same percentage of protein, carbohydrate and fat as has human milk. In this group are the cream and top milk mixtures and the butter-flour mixtures, also certain prepared foods such as Synthetic Milk Adapted (S M A), Lactogen and Similac. To this group belonged many laboratory prepared milks now obsolete (item 1, chart 1).

2 Budin's rule. The French obstetrician Budin,⁹ who made splendid contributions to pediatrics, advocated the use of whole cow's milk in the feeding of infants but insisted that the milk be sterilized. Budin estimated the amount of milk to be given as one tenth of the body weight. There is no doubt that sterilized whole milk can be successfully used in infant feeding, but many children do not thrive on it, Czerny observed such children and believed that many suffered from milk injury (milchnahr-schadung). The modern conception of the "injury" is that it is due to too little sugar rather than to too much milk. Budin sometimes added carbohydrate to the diet (item 2, chart 1).

3 Another European rule, devised by Pfandl, is as follows: "Take the tenth part of the infant's body weight in cow's milk and add to it one one hundredth of its body weight in carbohydrate, not exceeding, how-

¹⁴ Marriott W. M. *Infant Nutrition*. St. Louis, C. V. Mosby Company, 1930.

¹⁵ Holt L. E. and Howland John. *Holt's Diseases of Infancy and Childhood* revised by L. Emmett Holt Jr. and Rustin McIntosh, ed. 10. New York and London D. Appleton & Co., 1933.

feeding Parrot in the eighteen eighties not only used ass's milk but practiced direct nursing from the animals, which were quartered close to the nursery of the hospital. Attention is here called to the subject because of the fact that the ass is the only animal whose milk shows the caloric percentage pattern just described as that which seems to meet the nutritional needs of most infants satisfactorily.¹⁸ The caloric value of this milk is low, however 0.45 calory per cubic centimeter

INFANT MORTALITY

Every one is aware of the fact that there has been a tremendous reduction in mortality and morbidity from nutritional disorders of infancy. There has also been a downward trend in the total death rate from all causes, but the lowered death rate for children is so great that it accounts for a substantial portion of the total reduction. Attention is called to chart 2, showing the curve of the infant mortality rate in New Haven since 1875, correlated in time with various devel-

Mortality Statistics from Data of Grulee, Sanford and Herron

Group	Number of Infants	Mortality per 1 000 Infants			
		General	Respiratory Infections	Gastro-Intestinal Disturbances	Miscellaneous Infections
1. Breast fed..	2,749	1.54	0.41	0.20	0.72
2. Partially breast fed..	8,605	6.86	6.11	0.70	2.91
3. Artificially fed	1,707	84.38	48.04	8.20	19.33
Total	20,061	11.00	6.50	1.10	3.20
Ratio of mortality in group 1 to that of group 3..		1.50	1.115	1.40	1.27

opments in public health. The infant mortality trend for New Haven is typical of that of most other cities in this country and Europe. It would seem that the sharply downward trend of the curve began about 1895. Prior to this time the outstanding developments in public health had to do with the establishment of water supply and the disposal of sewage. It was in the eighteen nineties, however, that the various chemical, bacteriologic, vitamin and clinical studies which have been described were in full swing and were beginning to bear fruit through their application by various public health measures to large numbers of infants. Adequate training in pediatrics has been given only in the last two or three decades. No striking correlation of the curve of infant mortality with any individual scientific or educational development seems possible, but there is probably a summation effect of many factors forcing the curve downward.

The question may fairly be posed: Are all the problems of infant feeding solved? The answer without much doubt is "No."

The recent contribution of Grulee, Sanford and Herron¹⁹ is of great significance. (The accompanying table is prepared from the data of Grulee, Sanford and Herron.) Their study shows a striking disparity in mortality in a group of 9,749 infants wholly breast fed for nine months compared with that in a group of 8,605 infants only partially breast fed and in still another group of 1,707 infants wholly artificially fed. The

mortality in the first group was 1.5 per thousand, in the second 6.8, and in the third 84. The mortality from various causes is shown in the table to be relatively greater, especially in the artificially fed group from respiratory infections than from "gastro-intestinal disturbances." This probably means that the latter, in the sense of severe diarrhea and vomiting and marasmus, cause fewer deaths than more subtle nutritional disorders, which lead to greater susceptibility to infectious rickets, at least in former times, was such a nutritional disease.

It is probably true that unintentional selection was operative and threw into the class of artificially fed infants those who were in poorest health and whose mothers were least cooperative and attentive. However, it should be noted that all the infants received good medical and nursing supervision through infant welfare conferences, as is probably indicated by the fact that the total mortality in the group of 20,061 infants was 11 per thousand, whereas the total mortality for infants of this age period in Chicago was about four times that figure. Making allowance for selection and for errors inherent in statistical analyses of this kind, this study demonstrates that the practice of breast feeding is more successful than the practice of artificial feeding.

Specific limitations in artificial feeding present themselves for further study. What is the best method of feeding the premature infant and of controlling rickets and anemia? Should the diet be enriched in any respect after acute illness and how? What further studies can be made of the relation of food ingredients to gastro-intestinal rhythm? What further can be discovered about the relation of the hyperirritable gastro-intestinal tract to the autonomic nervous system? What is the relation of diet to the production of celiac symptoms, to disorders of the pancreas and to infections?

PSYCHOLOGIC ERA²⁰

It would appear, however, that in this field the most serious problem facing the physician at the present time has to do with the emotional life of the infant and mother, physicians are practicing and will continue to practice for some time at least in what might be termed the psychologic era in infant feeding. The available data concerning nutrition are doubtless fundamentally sound, but in applying the facts in the feeding of the infant his emotional life and that of his mother must be taken into consideration or else psychologic factors may become so disturbing that good nutrition is not attained. It is certain, in respect to the future of infant feeding, that the pediatrician must think not less in terms of principles of nutrition but definitely and decidedly also in terms of the personality of the child and of those in his immediate environment, especially, of course, of the mother.

Behavior problems seem at first glance to present themselves acutely, persistently and in great numbers in children at an older age period than that connoted by the subject of "infant feeding." But these problems of the preschool and school child express in a more

mature pattern emotional reactions the basis for which was established in infancy, the expression will be different at various intellectual and motor levels, but the underlying psychologic disturbance may be much the same.

Even in breast feeding there arise emotional problems. There are some infants who seem to be "breast shy," even when the mother has plenty of milk, such infants will not suckle although they will take the bottle willingly. There are other infants who never nurse or eat well, constitutionally they seem uninterested in food, although the possibility of a conditioned antagonism and negativism cannot be excluded. Another source of difficulty is the transition from the maternity ward to the home. The mother at home has more cares, more distractions and worries, her milk lessens, the baby cries, the mother gets more anxious and tense and a vicious circle is established. The mother and baby are now the center of a severe emotional storm which, in a majority of cases, could have been prevented had the physician had sufficient insight, understanding and patience to prepare the mother for what might happen.

The psychologic factors play a more important role, however, in artificial feeding. In the past emotional difficulties were not recognized as of major importance since they seemed to be present only in isolated cases, but now these problems are widespread, constituting a major portion of the practice of many pediatricians. The reasons for this increase are many, the problems are sequelae, in part—possibly in large measure—of a strict, dogmatic attitude in the application of the advances in the science of nutrition to the practice of infant feeding. Pediatrician and mother alike have the "itch" for regulation growing out of aspirations for perfection in dietary regimen and habit training and as a direct result of the propaganda for weighing and measuring—in short for standardization. In commenting on the percentage method of feeding, Jacoby once remarked caustically that "feeding cannot be regulated by mathematics so well as by brains, and by the wants of the individual child." Today he would probably say that "you cannot by laboratory methods feed babies on 'thirty-seven individual substances essential for a complete diet', the baby and the attitude of his mother have something to do with what is ingested even if they are ignored as to what is prescribed."

The successful experiment of Dr. Clara Davis²¹ in Cleveland and Chicago of allowing infants of weaning age²² to exercise choice in the amount and kind of food that they might eat constitutes a most challenging piece of work. It should remind the pediatrician that the normal breast fed infant, while he has no choice as to the kind of food he receives, is not regulated as to the amount nor strictly, in the unsophisticated home, as to meal time, his hunger cries are usually rewarded and the clock is often ignored. The artificially fed infant, on the contrary, is much more strictly limited as to quantity and meal time, his appetite is almost totally disregarded. When in the usual course of events such a carefully regulated infant is offered solid food at about 5 or 6 months of age he may rebel, the mother,

owing to the uncompromising attitude which the preceding six months' strict regimen has engendered, becomes disturbed and anxious. Instead of taking a purely passive attitude the mother becomes tense and aggressive and attempts forced feeding, and there follow the inevitable consequences—refusal of food, vomiting, sleeplessness, querulousness. Over and over again one can date the beginning of behavior problems of later infancy and of the preschool period to the time when solid food was introduced into the dietary regimen. The mother who has been narrowly trained in the precision of regular hours and measured amounts of carefully prepared milk mixtures is totally unprepared to handle the first act of rebellion.

Similar situations arise when weaning occurs precipitately in later infancy, when cup or spoon supplant bottle and when too aggressive attempts are made in the giving of orange juice or cod liver oil, and in establishing strict regularity in habits of sleep and elimination. Less emphasis on regularity and quantity, more elasticity in the care of the child, casual, early acquaintance (i.e., before 3 months for most of the objects and substances listed) with the rubber nipple, spoon and cup, water, orange juice, cod liver oil, solid food—all of this for the sake of training as well as for intrinsic merit, and, above all, education of the mother to utter passivity in the presence of evidences of nonconformity will usually prevent difficulties of an emotional nature. It is obvious that emphasis is being made here less on infant feeding per se and more on the attitude and training of the mother.

Of course, there are many other factors in the background of these emotional disturbances—the fundamental make-up of the child, racial stock, the small family with excessive concentration of attention on one or two children, the tension and complexities of modern life, thwarted social and economic ambitions, the desire to "keep up with the Joneses" in respect to the handling of infants as in everything else. Undoubtedly most parents expect too much of their children, especially of the first born.

This approach to the problem in which the education of the mother concerning the emotional as well as the physiologic reactions of the infant to the nutritional elements in his diet may bring forward the criticism that the child will be undisciplined, "spoiled." The criticism is perhaps largely academic, if the conception under discussion has been adequately presented. There are a sufficient number of required conformities even in an infant's life to insure the development of reasonable discipline. Some things in infant feeding are clear cut definite, certain, there are others which permit wide latitude for wise and sympathetic interpretation. For example, there is no basis in physiology for giving every 10 pound (4.5 Kg.) infant exactly 500 calories of a milk mixture which is to be given in exactly 6 ounce (170 cc.) doses every four hours by the clock with one feeding omitted. However, it is reasonable to consider that the average 10 pound infant would require about 500 calories and should not be urged to take that number if not hungry nor forbidden to take more if hungry. Perhaps at some feedings he will want more than 6 ounces and sometimes less, he may want some feedings at six hour intervals and some at three. No plea is being made for irregularity for irregularity's sake, but a protest is being made against inflexible standardization for its own sake. It would be wise for the physician to worship the baby more and the measuring stick, the scales, the graduate and

²¹ Davis Clara M. Self Selection of Diet by Newly Weaned Infants. *Am. J. Dis. Child.* 36: 651 (Oct.) 1928. Self Selection of Diets by Infants. *Ibid.* 40: 905 (Oct.) 1930.

²² Dr. Davis in a personal communication to the author has recently described a similar study (to be published) with three breast fed infants taken from lying in hospitals at the ages of 10, 8 and 7 days respectively and kept continuously on the experiment for periods of seven and one half to eight months. The results of the study are strikingly in accord with those obtained with the older children.

the clock less, there was a time not so long ago when the infants' stools would have been included in this interdicted list

If a battle impends in the handling of the child, the conflict must be won by strategy and not by force—a weapon that has so small a place in the armamentarium of the pediatrician as to be always invisible and rarely used, the ingestion of food never can be actually forced. As with the horse, you can lead a baby to water but you cannot make him drink. Food swallowed unwillingly by means of such tricks as bribing or diversion is often vomited.

CONCLUSION

It should be clearly understood that while I believe that the importance of an understanding of the emotional aspect of the feeding of infants is too little appreciated and that the chief problem at present arises in this domain, no real achievement in the newer knowledge of nutrition is thereby ignored. The most important aspect of the emotional problem in infant feeding is recognition that the problem exists and to a large degree may be prevented if the physician has insight and understanding of the personality of the mother and takes pains to prepare her to meet situations that are bound to occur in every case. The physician may need the assistance of a psychologist or a psychiatrist or both in therapy, but the burden of prevention is wholly that of the physician who guides the feeding. Here, if anywhere, "an ounce of prevention is worth a pound of cure." But prevention means understanding, insight, tact and patience. The physician must have all these qualities, and he must devote a great deal of time to the handling of these cases. Our psychiatrist, Dr. Marian Putnam, tells me that her most serious cases are those in which a tactless, brusque physician has scolded or otherwise occasioned resentment or feelings of guilt and inadequacy on the part of the mother. "Never show irritation at an unreasonable mother" is always a safe rule for the physician to follow.

The attitude of mind that I believe the physician should have himself and should inculcate in the mothers of his little patients is very effectively expressed by Ralph Waldo Emerson in the following passage from his *Essay on Education*:

I believe that our own experience instructs us that the secret of education lies in respecting the pupil. It is not for you to choose what he shall know what he shall do. It is chosen and foreordained, and he only holds the key to his own secret. By our tampering and thwarting and too much governing he may be hindered from his end and kept out of his own. Respect the child. Be not too much his parent. Trespass not on his solitude.

But I hear the outcry which replies to this suggestion: Would you verily throw up the reins of public and private discipline, would you leave the young child to the mad career of his own passions and whimsies, and call this anarchy a respect for the child's nature? I answer, Respect the child, respect him to the end but also respect yourself. Be the companion of his thought the friend of his friendship, the lover of his virtue and the imperturbable sligher of his trifling.

Heart Disease and Pregnancy—No woman who has once had heart failure should risk pregnancy. No woman with auricular fibrillation or heart block or history of rheumatism or considerable cardiac enlargement with or without valvular disease should be allowed to become pregnant.—Dr. K. D. INFECTIOUS MONONUCLEOSIS

PART I CLINICAL ASPECTS

C. A. McKINLAY, M.D.
MINNEAPOLIS

The fact that infectious mononucleosis is reported chiefly from institutional groups suggests that its recognition in private practice is not common. This is to be expected because of the benignity of the disease and its similarity to relatively brief systemic infections which may not suggest the necessity of making supplementary leukocyte and differential blood counts. This disease entity will be commonly recognized only when its symptomatology becomes of interest to the clinician and when its characteristic lymphocytic blood reaction can be demonstrated with a fair degree of regularity.

The statements (which will be challenged) of such competent hematologists as Kracke and Garver¹ that morphologically the disease cannot be distinguished with certainty from acute lymphatic leukemia emphasize the need for a survey of recent reports.

The present paper is based on data acquired over a period of twelve years. Although it may be presumptu-

Chart 1—Outstanding symptoms and physical signs in order of frequency in fifty cases (thirty-eight male, twelve female) of infectious mononucleosis.

ous to speak of a disease entity before the etiology is established, the clinical characteristics of the patients in this group have been well defined and have been adequate to make possible the recognition of most of the sporadic cases reported from a rather large service for infectious disease. Even before the notation of Paul and Bunnell² that the serum of each patient with this disease rather specifically showed sheep cell agglutinins, which observation strengthened the probability of its entity and became an added diagnostic test, the constancy of the clinical aspects and the blood picture in the sporadic cases reported herein had been impressive, that is, the clinical diagnosis was repeatedly confirmed by a detailed study of the morphology of the blood.

The present study supplements our publication of 1923,³ which appeared under the descriptive title of "Acute Lymphadenitis Compared with Acute Lymphadenitis."

From the Students Health Service, University of Minnesota. Read before the Section on Practice of Medicine at the Eighty-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., June 14, 1935.

tic Leukemia," which, in turn, followed the report of similar cases by Sprunt and Evans,⁴ Bloedorn and Houghton,⁵ and Longcope⁶ in 1920, 1921 and 1922, respectively. Sprunt and Evans' term "infectious mononucleosis" has been commonly used in this country. We have used their term in order to avoid the rather loose use of the term "glandular fever," which is sometimes found in the literature and which embraces such conditions as cervical adenitis.

Lehndorff and Schwarz⁷ in their complete survey of the literature on glandular fever describe two main groups: (1) the Pfeiffer⁸ or glandular type and (2) the anginose type. The enlargement of the lymph nodes in the former and the involvement of the throat in the latter were the predominating features. These observers

21 years. The age and sex incidence reflects that of the student body in which the cases occurred, and the age incidence is in keeping with the general tendency toward frequency in children and young adults and toward rarity in those over 40. The onset is associated with the following conditions, those without early angina sometimes having its late appearance (chart 1):

- 1 Angina or infection of the upper respiratory tract, 54 per cent
- 2 Systemic febrile reaction, 20 per cent.
- 3 Abdominal symptoms, 16 per cent
- 4 Adenopathy, 10 per cent

Generalized enlargement of the lymphatic glands was the outstanding and constant clinical feature. Occa-

Chart 2—Temperature and pulse rate in three cases—two of the patients had leukopenia at the onset and later lymphocytosis

considered that cases described as monocytic angina are of the anginose type. They were unacquainted with a prolonged febrile type with the maculopapular rash described by Tidy.⁹

CLINICAL DATA

The present study is based on observations made in fifty cases in university students, thirty-eight males and twelve females, aged 19 to 27, with an average age of

sionally it was striking enough subjectively to be the presenting symptom. The adenopathy apparently began and reached its maximum in the cervical triangles, often asymmetrically, with involvement of the left nodes more frequently predominating. The posterior cervical lymphatic chains were constantly enlarged, those in the anterior triangle of the neck being less prominent. The extent of the adenopathy was out of proportion to the intensity of the lesion in the throat and was especially striking in the absence of angina or pharyngitis. The deep cervical nodes were massed in some cases under the sternomastoid muscle about its middle and somewhat below the angle of the jaw. Otherwise, the individual nodes were discrete, somewhat soft and elastic and rarely exquisitely tender, indeed, usually there was no appreciable pain. They reached a maximum of 3 cm. in length. They lacked the periglandular redness, swelling and edema sometimes noted in cases of cervical

adenitis subsequent to oral infection and scarlet fever. Suppuration did not occur and has rarely been reported. The posterior auricular nodes were not usually enlarged—in contrast to the adenopathy noted in cases of rubeola. The axillary and inguinal nodes were rather constantly enlarged and were distinguishable from the smaller firmer nodes of the occasional axillary and frequent inguinal adenopathy which occurs in healthy persons. The epitrochlear nodes were frequently palpable. Enlargement of the hilum and abdominal nodes was not demonstrated in our series.

Signs of throat infection were present in 78 per cent of cases. 1 Most frequently there was marked injection of the fauces with swelling of the lymphoid tissue, the so-called granular pharyngitis. 2 Less commonly, a membranous angina indistinguishable in appearance from that of diphtheria developed. 3 Occasionally, follicular tonsillitis or pharyngitis existed. The faucial changes appeared late in about one third of the cases with an onset characterized by the other predominating systemic abdominal or glandular symptoms. The spleen was palpable in 42 per cent of cases, its margin soft and its size never great. One instance of maculo-

Chart 3—Classification of the temperature for groups with related leukocyte and differential counts also average counts grouped according to days after the onset.

popular rash was noted. Three other cases were classified as toxic rashes simulating dermatitis due to some drug. No complications occurred and complete recovery resulted in all cases as far as known, although enlargement of the lymphatic glands sometimes persisted for twelve months after the onset of the infection. Recrudescence of symptoms was noted occasionally (chart 2).

The infectious features varied but fever was almost always present with malaise, headache, sweating and chills, listed in the order of frequency. Prostration was not so marked as in cases of acute tonsillitis. The temperature reached a maximum of 103.8 F, usually not reaching 103. It was irregular and showed wave-like recrudescences in the more prolonged cases and lasted up to three weeks in the patients with higher temperatures and for four months in one subacute case in which there were minimal temperatures. The pulse rate, which was relatively slow, varied directly with the temperature. Defervescence was by lysis, contrasting with the fall by crisis not uncommonly encountered in cases of tonsillitis. Jaundice occurred in five cases, in three, combined with gastro-intestinal symptoms, it subsided with defervescence. An infectious origin of jaundice is suggested although Mackey and

Wakefield¹⁰ reported a case of obstructive jaundice which they thought was due to obstruction of the common duct by lymph nodes (charts 3 and 4).

The total leukocyte and differential blood counts were striking and emphasized the fact that differential counts must be made. Lymphocytosis, relative and absolute, was 50 per cent or greater in all cases at some time during the course of the disease. The initial

Chart 4—Repeated counts in individual cases with occasional leukopenia or neutrophilic leukocytosis followed by sudden lymphocytosis.

leukocyte count was 5,000 or less in eleven of fifty cases and reached a minimum of 3,300 in one case, and in four of the eleven never reached a level of 10,000 or over. The maximum count was 32,550. Leukocytosis of 10,000 or over occurred at some time in forty of the fifty cases. The percentage of granulocytes noted in initial counts was known to drop as much as 63 per cent as the leukopenia gave way to moderate leukocy-

Chart 5—Date of onset in fifty cases.

tosis. Lymphocytosis appeared to be greater in the patients with higher temperatures. There were numerous records of patients who had had other infections before and after glandular fever with the usual polymorphonuclear response. These records indicate that the lymphatic reaction to glandular fever is not on a constitutional basis but is a response to a definite type of infection.

10 Mackey R. D. and Wakefield E. G. Occurrence of Abnormal Leukocytes in Blood of Patient with Jaundice (Infectious Mononucleosis—Glandular Fever). *Ann. Clin. Med.* 4: 727-730 (March) 1926.

The urinalyses were not remarkable, hematuria, which has been noted by some authors, did not occur. A critical study of the hemoglobin and the red blood counts was not made, although the impression of the absence of appreciable anemia was obtained.

The study of the etiology included the making of direct smears and occasional cultures from the throat, but no characteristic observations were made. The occasional finding of Vincent's organism was not more significant or frequent than in cases of other types of infections of the throat. Blood cultures were repeatedly negative. Emulsions of fresh glandular substance made during the acute stages were injected into monkeys and guinea-pigs without demonstrable effect. The Forssman reaction was present in dilutions of 1 to 32 or greater in the serum in five of ten cases. No confirmed studies as to etiology have been reported although Murray, Webb and Swann¹¹ in 1926 found that *Bacterium monocytogenes* was the etiologic basis for a disease in rabbits characterized by pronounced monocytosis and Nyfeldt¹² in 1929 reported the isolation from the blood of an organism which he called *Bacterium monocytogenes-hominis* and with which he produced the cellular blood picture in rabbits. Gorham, Smith and Hunt¹³ reported blood changes in the guinea-pig following inoculation of pharyngeal exudate from a patient with a severe case of Vincent's angina, while in persons who have been in contact with experimental animals infectious mononucleosis has developed. However, this work has not been confirmed. The sheep cell agglutination reaction recently has been studied critically by Bailey and Raffel¹⁴. They confirmed its apparent constancy in the disease and emphasized its importance, but stated that a heterophil or Forssman antibody is not responsible for the reaction, that the antibodies are not found in normal serum but are rather a specific response associated only with infectious mononucleosis. The symptomatology suggests that the gastro-intestinal tract, in addition to the upper respiratory tract, must be considered as a possible portal of entry of the etiologic agent (chart 5).

While glandular fever characteristically occurs in epidemics, our series consisted of sporadic cases of fairly even monthly distribution. The incubation period was given by Lehdorff and Schwarz as seven or eight days, with usually short prodromal periods. The degree of infectivity must be low as we have not seen proved contact cases, although four cases occurred in laboratory workers in bacteriology, two coincidentally. Two brothers living together had the disease four years apart. Four of eight patients in whom the disease occurred within two months had similar gastro-intestinal symptoms.

DIFFERENTIAL DIAGNOSIS

If the possibility of infectious mononucleosis is kept in mind by the clinician, the errors of omission will be less frequent, and there will be fewer cases left in that residuum of acute systemic infections sometimes unclassified or covered with a general term such as influenza. The most common confusion arises from tonsillitis and pharyngitis of other origin with secondary cervical

adenitis. In our first encounter with infectious mononucleosis in 1921, a case was clinically confused with acute lymphatic leukemia because of the additional feature of hemorrhagic areas in the buccal mucosa, only five other similar cases have been reported according to Tidy.⁹ The persistent, often localized adenopathy of Hodgkin's disease and tuberculous adenitis were not suggested in any instance, syphilis has not existed clinically or serologically in this group. The cases in which there were abdominal symptoms might well be confused with acute gastro-enteritis or appendicitis, but the absence of signs of peritoneal irritation with its concomitant adenopathy and blood picture has been adequate to differentiate this condition. We have not noted cases of involvement of the central nervous system as reported by Johansen¹⁵ and by Epstein and Dameshek.¹⁶

SUMMARY

The characteristic generalized adenopathy, frequent splenomegaly and lymphatic reaction of the blood make possible the recognition of sporadic cases of infectious mononucleosis occurring among a large group of patients with various acute infections. Angina may be late in appearance or entirely absent. The occasional appearance of abdominal symptoms should be kept in mind in order to avoid confusion with acute infections of the gastro-intestinal tract. Serial blood counts are not infrequently necessary in order to discover the lymphocytic reaction. The constancy of the adenopathy suggests that the essential lesion and habitat of the etiologic agent is in the lymph nodes.

INFECTIOUS MONONUCLEOSIS

PART II. HEMATOLOGIC STUDIES

HAL DOWNEY, PH.D.

AND

JOSEPH STASNEY, M.D.

MINNEAPOLIS

The blood picture found in cases of infectious mononucleosis was described in detail by Downey and McKinlay¹ in 1923. Their paper was accompanied by a colored plate illustrating the different types of lymphocytes seen in the blood smears of the patients studied up to that time. The reproduction of the original drawings was unusually good, and a photograph of this plate is reproduced in figure 1.

The lymphocytosis which follows the initial neutrophilic leukocytosis is usually characterized by the presence of very atypical leukocytoid lymphocytes, like those shown in cells 1 to 11 in figure 1. The lines in this illustration separate the cells found in the blood of three different patients with infectious mononucleosis and one patient with acute lymphatic leukemia (cells 12 to 14) that was added for comparison. There is considerable variation in the character of the atypical lymphocytes in different patients and for that reason it was stated that the patients can be divided roughly into three groups depending on the type of lymphocyte

which dominates the blood picture. These cells were described in the previous paper.

A continued study of the blood in this disease has shown that little can be added to the original description of the blood picture.¹ We have encountered an occasional patient in whom the lymphocytes were of fairly normal structure, usually they are the large atypical basophilic lymphocytes which show a tendency

Fig. 1—Cells 1 to 11 are lymphocytes from blood smears made in three cases of infectious mononucleosis. Cells 8 and 9 have immature nuclei. Cell 11 contains an Auer body. Cells 12 to 14 are immature lymphocytes from a patient with acute lymphatic leukemia.

to develop toward plasma cells. A few plasma cells are often found and in Angelini's² patient they were numerous but generally the cells fail to complete their development into plasma cells.

The abnormal morphology of the lymphocytes shows that the condition is not an ordinary lymphocytosis like that seen in cases of pertussis which is characterized by a great increase in the number of lymphocytes of normal structure, except in very young children, in whom many of them may be immature. The term 'lymphatic reaction' as used by Türk,³ Schwarz,⁴ and others is a better designation of the lymphocytic picture seen in cases of infectious mononucleosis.

Confusion has resulted from the fact that many investigators of this disease have believed that the large basophilic lymphocytes are immature lymphoblasts similar to those seen in cases of acute lymphatic leukemia. Further study in many cases, however, has shown that the cells are usually not immature and that the blood picture does not suggest that seen in cases of acute leukemia. The confusion is due to the fact that the criteria for judging the degree of immaturity of lymphocytes have not always been understood. This explains the recent conclusion of Stuart Burgess

Lawson and Wellman⁵ who followed Wiseman⁶ in expressing the belief that the basophilic lymphocytes are immature. Hematologists (Pappenheim, Ferrita Naegeli) have agreed that basophilia of cytoplasm is extremely variable in lymphocytes, the young cells may or may not be very basophilic, while plasma cells which are mature cells, are very basophilic. Genuine lymphoblasts, as seen in cases of acute lymphatic leukemia, have an extremely delicate leptochromatic nuclear pattern which is very different from that of the mature lymphocytes of normal blood. Three immature lymphocytes are shown in cells 12 to 14 of figure 1. In cases of infectious mononucleosis the nuclear pattern is often even coarser than it is in normal lymphocytes owing to the tendency of these cells to develop into plasma cells. Lymphoblasts approach the structure of myeloblasts and the nuclear structures may be identical if the cells are sufficiently immature. Lymphoblasts of this type are not often seen in cases of infectious mononucleosis.

In our first series of nine cases there was one case in which a few of the lymphocytes were both immature and 'leukocytoid'. These are shown in figure 1, cells 8 and 9. The cytoplasm of these cells is not as basophilic as that of cells 1 to 6 but the nuclear pattern shows the delicate, leptochromatic structure that characterizes immature nuclei. An occasional cell of this type contained an Auer body, and some had nucleoli.

Therefore, a few immature lymphocytes are found in some cases of infectious mononucleosis. The two

Fig. 2—Section of a lymph node removed for biopsy from a patient with infectious mononucleosis. This low power view shows the nodular hyperplasia of the reticulum and the obliteration of the architecture of the node.

cells illustrated (cells 8 and 9) are the youngest found in our earlier and later series. They are not sufficiently immature to be called stem cells or lymphoblasts. That

the latter may occur in this disease is proved by the beautiful and accurate colored figures published by Schwarz,⁴ and the descriptions of Glanzmann⁷ and Nyfeldt⁸ among others. These authors have stated that the immature cells are of infrequent occurrence and that they are never numerous. Mitosis and anitosis of lymphocytes has been described by several authors but was never seen in our series.

Fig. 3.—Same as figure 2 but with higher power.

We have frequently found lymphocytes that were slightly immature but never sufficiently so to cause difficulties in differentiating the case from one of early acute lymphatic leukemia. Schwarz⁴ expressed the belief that some cases in which there are a few very immature lymphocytes in the blood might be mistaken for cases of early leukemia. We believe, however, that the 'leukocytoid' character of the lymphocytes is sufficiently specific to enable one to distinguish between the benign and leukemic forms. The presence of toxic neutrophils and the shift to the left in the Schilling sense are other features which enable one to decide in favor of the benign condition.

This blood picture is not absolutely specific for infectious mononucleosis. We have seen one case in which the blood picture of infectious mononucleosis and total leukocyte count of about 15,000 changed to fatal agranulocytosis with a total count of 800. In another case of agranulocytosis, all the granulocytes were lost from the blood for a period of three days. The total count of leukocytes composed of leukocytoid lymphocytes and a few monocytes did not fall below 1,400 and the patient recovered. A similar lymphatic reaction has been seen also in a case of septicemia. Such confusing cases are fortunately very infrequent. Hematologically (without the history), they may be mistaken for cases of infectious mononucleosis but never for cases of acute leukemia.

Examination of biopsy material from the lymph nodes in eight cases suggested an explanation for the occurrence of immature lymphocytes in the blood smears in some cases (fig. 1, cells 8 and 9). These immature cells may be as atypical as the mature ones, the immaturity being indicated by the delicate leptochromatic nuclear structure and the presence of nucleoli.

The patients from whom the nodes were removed showed different degrees of severity of the disease and the biopsies were performed at varying periods after the onset of the disease. This undoubtedly explains the variations in the degree of pathologic alteration noted. The material was studied in sections and also by the dry imprint method, the May-Grünwald-Giemsa stain being used. The cytologic detail of the imprints is about as good as that of the blood smears which makes this a very useful method for tracing the origin of the atypical lymphocytes of the blood.

The architecture of the nodes showing the greatest alteration is completely obliterated and there is marked hyperplasia of both lymphocytes and reticulum. This hyperplasia is not uniform. Dense areas of lymphocytes alternate with areas in which the lymphocytes are scattered and the hyperplasia of the reticulum is more pronounced. In the denser areas the lymphocytes are fairly uniform in size, and a section through such a region gives a picture much like that seen in cases of chronic lymphatic leukemia. The lymphocytes show great variation in size and structure in the regions where they are scattered and where hyperplasia of the

Fig. 4.—Same as figures 2 and 3, high power. The rounding up of the reticular cells is shown in the central portion of the section.

reticulum is more pronounced. This hyperplasia involves groups of reticular cells which swell and become rounded and probably proliferate. This gives the sections the nodular or spotty appearance described by Pratt⁹ for this disease and by Nishii¹⁰ for the

¹⁰ Nishii, R. Ueber die Reaktion der regionalen Lymphknoten bei lokaler Infektion und Reinfektion. Krankheitsforschung 7: 335 (Oct.) 1929.

regional lymph nodes of guinea-pigs after subcutaneous reinfections with *Staphylococcus pyogenes-aureus* of weak virulence. This is illustrated in figures 2, 3 and 4, which are different magnifications of the same specimen of lymph node. In figure 4 these nodules of reticular cells often crowd out the lymphocytes.

One other node of the series showed about the same structure as that just described, and the others showed varying degrees of the same process. In one the sinuses were well preserved but filled with reticulo-endothelial cells, there were also remnants of follicles and germ centers. Nodules of reticular cells were seen in the looser tissue between the follicles and in the medulla. This node was removed two weeks after the onset of the illness. The leukocyte count did not rise above 13,200, with 79 per cent lymphocytes. A node from another patient in the series was normal for the most part and hyperplastic in one region. The other nodes were decidedly hyperplastic but to a varying degree. They all showed the nodular hyperplasia of the reticulum.

Even in the sections it is obvious that some cells isolate themselves from the nodules of hyperplastic reticulum and transform into lymphocytes. This is seen in the central portion of figure 4, where several cells have acquired narrow rims of basophilic cytoplasm and are isolating themselves from the main mass of reticulum.

The details of the differentiation of these cells into lymphocytes are seen best in the imprints, and several stages of the process are illustrated in figure 5. Cell 1 is a cell of the reticulum with a nucleus showing the specific structure that is characteristic for these cells. The delicate strands and fine granules of chromatin are very distinct and there is sharp separation between chromatin and parachromatin. In cell 3 the strands of chromatin have become much heavier and the nuclear pattern has approached that of the lymphocyte. The cytoplasm is just beginning to condense and acquire the basophilia of lymphocytic cytoplasm. In cell 2 the nucleus is still that of the reticular cell but the cytoplasm has become rounded and condensed and is distinctly basophilic. Cell 5 is a normal mature large lymphocyte, and cells 6 and 7 are undergoing metamorphosis into plasma cells, of which there are many in this material.

Intermediate stages similar to those illustrated are very numerous in material taken at the height of the disease so one must conclude with Schwarz¹¹ that there has been a marked shift to the left in lymphocyte regeneration to the extent that the reticulum becomes extensively involved in the process. There is some development of lymphocytes from reticulum in normal nodes (Downey and Weidenreich¹²; Mollier,¹³ Jolly,¹⁴ Maximow¹⁵) but the process is not as active as in cases of infectious mononucleosis.

Many of the large basophilic and leukocytoid lymphocytes seen in the blood smears are also found in the imprint preparations of material from the nodes and there is good correlation between the character of the lymphocytes of the imprints and the lymphocytes of the blood smears from the same patient. From this it seems obvious that many of the atypical lymphocytes

of the blood have assumed their abnormal features while still in the nodes. The correlation between the degree of hyperplasia of the nodes and the total leukocyte count is not so good.

There seems to be no relation between the basophilia of the cytoplasm and the degree of maturity of the lymphocytes. Any lymphocyte, large or small, mature or immature (as judged by nuclear structure), may become very basophilic, indicating that basophilia is not a good criterion for estimating the immaturity of a lymphocyte, as claimed by Wiseman.⁶

Some of the maturing and metamorphosing (Schwarz⁴) lymphocytes may escape into the blood before they have completed their development. This was evident when we compared blood smears with imprints made in the same cases. Lymphoblasts as seen in cases of acute lymphatic leukemia (fig 1 cells 12 and 13) are rarely seen in the blood smears. Only one lymphoblast of this type was found in our imprint material and is illustrated in cell 4 of figure 5. The few immature blood lymphocytes of infectious mononucleosis are more likely to be cells that show some

Fig 5.—Drawings of cells from dry imprint preparations made from lymph nodes removed from infectious mononucleosis. Cell 1 is an undifferentiated reticular cell showing details of the nuclear structure. Cell 2 is an immature lymphocyte which has been derived from the reticulum. Its nuclear structure is still much like that of a reticular cell. Cell 3 is a reticular cell in which the nucleus has differentiated and acquired some lymphocytic characters. Cell 4 is an immature lymphocyte (lymphoblast) with two nucleoli. This type of lymphocyte is common in cases of lymphatic leukemia but is rare in cases of infectious mononucleosis. Cell 5 is a basophilic mature large lymphocyte. Cells 6 and 7 are lymphocytes that are developing into plasma cells.

reticulo-endothelial characters in their nuclei. Most of them would have a nuclear pattern that is intermediate between cells 2 and 5 of figure 5. There is, therefore, a difference between even the very immature lymphocytes of the disease under consideration and the lymphoblasts in cases of acute lymphatic leukemia. Downey¹⁵ has shown that in the latter disease the regeneration of lymphocytes differs from the normal process. In infectious mononucleosis it proceeds according to the normal scheme except that the development from the reticulum is accentuated and many of the cells become atypical.

CONCLUSIONS

Examination of the biopsy material from the lymph nodes of patients with infectious mononucleosis shows that the hyperplasia of lymphocytes is not as extensive or as uniform as in cases of lymphatic leukemia. The

hyperplasia of the reticulum is due to swelling and proliferation of groups of reticular cells giving sections a spotty and nodular appearance identical with that described by Nishii after staphylococcal reinfections.

The changes in the nodes, together with the atypical structure of the lymphocytes and the increase in their number, indicate that the disease is due to infection with some organism or virus which has a very specific stimulating effect on the lymphocytes and reticulum and a depressing effect on the granulocytic system.

The blood picture is very characteristic but not absolutely specific, as there are some other types of infection which occasionally show the same blood picture.

ABSTRACT OF DISCUSSION

ON PAPERS OF DR. MCKINLAY AND DRS.
DOWNEY AND STASNEY

DR. A. H. GORDON, Montreal. There are a few thoughts that occur to one. The first is the natural fear of leukemia when this symptom complex comes to the fore, and to an experienced hematologist this fear probably becomes less and less. But I doubt whether there is any one who, on seeing a case of this sort, has not had a day or more of qualms lest the greater thing might be present when only the lesser appeared. The next thing that strikes one is the presence of this disease in people of early adult life and in my own experience it has been almost altogether among people connected with medical schools or with nursing schools. This fact would suggest that this may probably be a carrier disease and that it is probably much more common among the general public than has been thought. People in hospitals, medical schools and universities are much more likely to have routine blood examinations than is the general public. The final matter is the possibility of infectious mononucleosis occurring with little or no glandular enlargement but with predominant enlargement of the spleen. A student nurse of 21 left the hospital to undertake training in the maternity pavilion on the 14th of April and on the 17th complained of an infection of the upper respiratory tract. On the 21st she returned to the hospital with a temperature of 102, quite acutely ill, with an infection of the upper respiratory tract and a predominantly sore throat. She had no glandular enlargement but she had a very definite enlargement of the spleen. May 9 the temperature was normal no glandular enlargement had been noted except a week after onset, and following daily examinations of her glands two small spleen-sized glands had been found in the epitrochlear areas. At the end of her illness three weeks later, this girl had shown all the typical features of infectious mononucleosis with leukocyte counts running about 10,000 with an average lymphocyte count of 80 per cent, and polymorphonuclears of 20 per cent, the platelets ranging between 175,000 and 200,000. Otherwise there was a normal blood count and at the end of the time she still had an enlarged spleen and the almost imperceptible lymphatic glands. The following January her blood count still showed 58 per cent of polymorphonuclears and the remainder of lymphocytes. The points that would occur to me as of importance are the great possibility of error as between this and lymphatic leukemia, its presence in young adults (especially in institutions), and the possibility that the disease may show itself as a splenic hypertrophy and not as a predominantly lymphatic glandular hypertrophy.

DR. ISRAEL DAVIDSOHN, Chicago. I will limit my remarks to a discussion of the serologic nature of the so-called heterophilic antibodies in infectious mononucleosis. I found a markedly elevated titer of these antibodies in horse serum disease and my results were published in 1929. Paul and Bunnell observed, while checking my work in serum disease, that cases of infectious mononucleosis showed a similar rise of the antibodies. Since their publication in 1932 a large number of reports have confirmed their observations. The name heterophilic antibodies indicates that the blood of the sheep has no part in their production. Such antibodies are present in the serum of most normal persons and by means of proper absorptions it was shown that they belong to a special group of heterophilic anti-

bodies, the so-called Forssman group. To belong to that group the antibodies must react with the tissues of the guinea pig. I have shown that the heterophilic antibodies in horse serum disease belong to the Forssman group. In many recent reports the antibodies in infectious mononucleosis were referred to without justification as Forssman antibodies. When the serum of normal persons is treated with suspensions of the kidney of the guinea-pig, the agglutinins for sheep red cells are readily and thoroughly removed. When the serum from a patient with serum disease is similarly treated, the results are about the same. However, when the serum of patients with infectious mononucleosis is subjected to such treatment, the kidney of the guinea-pig fails to remove completely the agglutinins against sheep cells, but its effect is that of a nonspecific absorption. The absorption permits a serologic differentiation of infectious mononucleosis from serum disease. There are not infrequently patients with clinical and hematologic signs suggesting infectious mononucleosis in whom the titers of heterophilic antibodies are in the so-called borderline group according to my technique. By means of the absorption test it is easy to separate such cases from true serologic infectious mononucleosis. It may become necessary to divide infectious mononucleosis into two groups—a seropositive and a seronegative.

DR. C. A. MCKINLAY, Minneapolis. Dr. Gordon's experience in which splenomegaly was a predominating feature is new to us. With regard to the agglutination tests our experience is limited to eleven cases in six of which it was positive in significant titers. An occasional diffuse erythematous rash similar to a toxic drug rash has been observed. Tidy described a rash similar to typhoid in epidemics in England. We feel that if the clinical picture of this disease is emphasized and if the hematologic changes as described by Dr. Downey are recognized general interest will be enhanced and the study of the etiology advanced for who could deny the importance of the study of the etiology of this disease, which is so close in certain rare features to acute lymphatic leukemia?

XANTHIC LESIONS

REPORT OF FOUR CASES, INCLUDING TWO OF
"XANTHOMATOSIS" OF THE KIDNEY

M. M. MELICOW, M.D.
NEW YORK

The finding of an orange-yellow nodule in a tissue or organ is usually of arresting interest. Orange plaques on eyelids are a common and striking occurrence, and similar skin tuberosities are occasionally seen on the knees, elbows and hands, golden-brown nodules sometimes develop about tendon sheaths and joints rarely a sinus tract discharges an amazing orange pus and leads to a similarly colored granuloma, the dull yellow of a hypernephroma sometimes displays a distinctive reddish-brown nodule, and a carcinoma of the prostate is discolored very infrequently by a similar process. Finally there very rarely occur generalized golden-yellow infiltrations as the most striking effect of an unusual constitutional deficiency. To this miscellaneous group of clinical and anatomic conditions the term 'xanthoma' introduced by Lebert in 1845 and again by W. F. Smith in 1869 to denote a yellow fibrous tumor, has been rather indiscriminately applied. The common denominator in all has been the color. Considerable confusion has resulted, because both the accumulations and the discolorations are often secondary or accidental to more significant pathologic processes, which may be inflammatory, traumatic, degenerative deficiency or neoplastic. Furthermore, a number of different intracellular or extracellular substances can induce a similar color effect. The term

has been applied in the absence of the characteristic yellow because of the presence of the typical foam cells. Thus at the outset it is obvious that xanthoma as a general term is inadequate and that the prefix "xanthic," preceding that term which accurately characterizes the underlying condition is more logical in most instances.

THE PIGMENT

The egg-yolk color of a xanthic mass has been variously attributed to intracellular lipochrome pigments, hemoglobinogenic pigments, or both. Extracellular hemosiderin, old blood clot, or even melanin may simulate it. Bloodgood,¹ Reid and Garrett² state that in xanthoma the discoloration is obtained from destroyed blood. They refer to the connective tissue tumors associated with tendons and joints. Geschickter and Copeland,³ in discussing these tumors, which they believe arise from sesamoid bones, state that the color is due to either lipid or blood pigment. Siemens has shown that the yellow coloration of xanthomas associated with a disturbed lipid metabolism is derived from the lipochrome pigments carotene and xanthophyll. Miller⁴ points out that it is through the combination of these pigments with the otherwise colorless cholesterol esters that the color characteristic of xanthomas result.

D. T. Smith⁵ distinguishes two groups of xanthic entities: (1) those in which the color is due to lipid pigments contained in the lipid substances of their foam cells and in which blood pigments are absent, and (2) those in which the color is due largely to the intracellular blood pigments in which foam cells are inconspicuous. Pick,⁶ however, contends that with lipid storage of every sort there is a tendency to simultaneous storage of hemoglobinogenic pigments and, furthermore, that with every added stimulation of the reticulo-endothelial system there occurs an increased hemosiderosis, that is, an increased blood destruction. I have noted the presence of fresh and old blood in xanthic masses that are associated with degenerations within neoplasms. Smith admits also that in the second group additional coloring is derived in some cases from the lipid substances within the rare foam cells. Thus it would seem that the distinction between the two groups is one of degree, in one the pigment is mainly lipochromogenic and in the other it is largely hemochromogenic.

The xanthic masses of Smith's first group result, in some instances, from lipophagic activity following inflammatory or degenerative processes, and in others they constitute infiltration structures due to a disturbed lipid metabolism. The orange-yellow spottings seen about old pus pockets, along sinus tracts and in broken down neoplasms and the 'pseudoxanthomas' of some authors are examples of xanthic granulomas. Xanthoma palpebrarum and xanthoma multiplex are probably

degenerative phenomena, for which the terms xanthic granuloma palpebrarum and xanthic granuloma multiplex would seem more suited. The deposition of cholesterol-containing xanthic masses about elbows, hands and knees, associated with a hypercholesteremia as in some cases of diabetes (xanthoma diabeticorum), chronic liver disease and so on are like tophi in gout.⁶ Here the added factor of local irritation induces an apparently selective reaction and infiltration. The constitutional xanthomatoses, described by Pick and others, are expressions of a general dyslipoidism with marked, often diffuse, xanthic infiltrations. Occasionally Smith notes, the cells of a neoplasm become infiltrated with cholesterol as a consequence of a local disturbance without there being any degeneration. The mother cells of these neoplastic cells physiologically contain cholesterol fat. The xanthocarcinoma of the prostate, xanthic tumors of the adrenal and 'xanthome en tumeur' of the skin and mucous membranes are instances of this development.

In the second group, the blood pigment containing group, Smith identifies true neoplasms. They occur as encapsulated and lobulated benign connective tissue tumors, associated with tendon sheaths or about joints. They are composed mainly of spindle or round cells, some giant cells and foam cells and a brown pigment, hemosiderin. The term xanthoma is reserved by many authors for this type of deep orange mass (some call it solitary xanthomatous giant cell tumor). However, it is a question whether they are true tumors of connective tissue origin with incidental admixture of xanthoma cells and secondary hemochromophagyn (xanthic fibroma or xanthic endothelioma or xanthic histioma), or whether they are granulomas following trauma of the tissues (xanthic granulomas).

The atheromatous plaques of arteries are identical in color with xanthoma.⁷ Here the yellow is seen through a layer of pearly white endarteritis. When the intimal covering is incised, a grumous slimy, yellowish material may be squeezed out, and there is a tendency to calcification with advancing years. However, microscopically, the lesion is similar to xanthoma through the presence of typical foam cells containing cholesterol esters, fatty acids and neutral fat. They represent the reticulo-endothelial response to a local excess of lipoids, and the latter may arise from the trauma resulting from the constant pounding associated with the concomitant hypertension and cardiac hypertrophy. Atheroma may also be experimentally produced by feeding animals with a diet high in cholesterol.

There are a number of lesions which resemble in color the so-called xanthomas but which are in no way related. Thus, Bloodgood calls attention to a certain type of hemangioma (fibrohemangioma⁸), which because of hemorrhage and secondary accumulation of blood pigment has been erroneously diagnosed xanthoma. Similar difficulties arise in hemorrhagic buritis, hemorrhage in a lipoma, myxoma or fibromyxoma.

The cream colored subepidermal nodules, which when coalesced appear as yellowish striae in the loose skin in a case of pseudoxanthoma elasticum is not to be confused with xanthoma. Instead of fatty degeneration there is an extensive degeneration of the deep elastic fibers of the skin. There are no foam cells though giant cells are sometimes seen. Sugg and

Stetson⁸ reported two cases of pseudoxanthoma elasticum associated with angioid streaks of the retina and diabetes

In fat necrosis, such as is seen in traumatic fat necrosis of the breast, the neutral fat is broken up into droplets which are attached eccentrically to the wall of the fat cell envelop. The necrotic and liquefied areas are surrounded by abundant newly formed connective tissue. The gross appearance may resemble "xanthoma," but the microscopic changes are quite different.

In brief, the color range of a xanthic nodule is the resultant of the sum total of its preponderant fat (orange) or blood pigments (brown). In the latter instance the pigment is contained in the cytoplasm of the cells that collect these foreign bodies into clumps of irregular size and shape. It gives the prussian blue reaction for iron. In the former instance, by far the

Fig. 1 (case 1)—Cross section of kidney showing diffuse xanthomatosis

more common and predominant feature of xanthic masses, the sudan III or scarlet red stain produces a striking picture because the accompanying lipid globules take on a deep red. Melanin granules are usually smaller and more uniformly distributed in the cytoplasm. Melanin does not give the iron reaction but stains with silver, while iron and fat do not.

THE 'FOAM CELLS'

The cytoplasm of a stained lipid-laden cell from a xanthic mass is filled with tiny vacuoles and therefore appears meshy or "foamy" (fig 2), because its fatty globules have been dissolved in the process of preparation. The "foam cell" therefore is considered by many as the building block of xanthoma and peculiar to it.

The cells that are adapted to the inclusion of lipids, lipochromes, and as already noted blood pigments are derived from the reticulo-endothelial system. The cell

elements of this system, with their remarkable affinity for dyes and particulate matter as well as lipoids, are found in the liver (Kupffer cells), the spleen and lymphoid tissues (reticulum cells), the bone marrow, the connective tissue of the body generally (the histiocytes), and the blood (monocytes). All these cells though in different locations, are identical in nature and function and may be looked on as of a single type cell. They are scavengers, capable of locomotion and of changes in size and activity. The lipophagic response of these "resting-wandering" cells can be local or general, depending on the extent and nature of the disturbance, and results in the characteristic formations seen in a xanthic mass.

There are other cells, nonhistiocytes, that normally contain lipoids (cholesterin esters) and may appear foamy, as, for example, groups of cells in the corpus luteum, thymus, hypophysis, puerperal uterus, gallbladder mucosa, testis, thyroid, sebaceous glands, and the cortex of the adrenal. The rare occurrence of foam cells in neoplasms, the mother cells of which physiologically contain fat, has already been noted. Thus cell "foaminess" alone is not pathognomonic of a xanthic mass, and neither is the orange color, but the combination is characteristic when it represents a reticulo-endothelial lipophagic response.

THE LIPIDS

The character of the intracellular lipoids in xanthic entities is not constant. In the localized forms one usually finds cholesterol. Chemical, physical or bacteriologic agents may liberate this ester, the presence of which incites the phagocytic properties of the histiocytes. In some of the generalized forms the infiltrations with cholesterol represent selective storage from a hypercholesteremia. In the constitutional forms the xanthomatoses kerales, phosphatids and cholesterol have been identified. Here there is an intense dyslipoidism, probably the result of a chromosomal or constitutional defect. A number of clinical forms have been identified. They vary in acuteness or chronicity of the process and in the extent of the xanthic infiltrations. Niemann-Pick's disease, Grucher's disease, Hand-Schuller-Christrén's disease and possibly Tay-Sachs's amaurotic family idiocy are examples. The notion as to the genotypical origin of the syndromes is further strengthened by the congenital tendency and the accompanying degenerative stigmas. It may be that xanthic granuloma palpebrarum, multiple xanthic dermatosis and xanthic granuloma diabeticorum are of a similar constitutional disturbance, though milder in degree. A hereditary tendency, obesity, diabetes and hepatic disease are frequent concomitants.

XANTHIC ENTITIES

Definition—The usual xanthic mass has an orange color and is composed of large cells containing lipoids, commonly cholesterol. The lipid-laden cells appear as "foam cells" when stained by ordinary methods and the lipid droplets are a brilliant red when sudan III or scarlet red is used. They represent the response of the reticulo-endothelial system to an excess of lipoids, either local or general. Included under xanthoma are other orange colored masses, which, however, differ in basic construction. Thus, there is the "xanthoma" of tendon sheaths, which is regarded by some as a foam cell neoplasm (or histioma or reticulo-endothelioma) and by others as a fibroma with a secondary xanthic

⁸ Sugg, E. S. and Stetson, D. D. Pseudoxanthoma Elasticum
I. A. M. A. 102: 1369-1371 (April 28) 1934

response "Foamy" formations are seen also in neoplasms the parent cells of which physiologically contain fat. They probably represent a local dyslipoidism but cannot be regarded as representative of a reticulo-endothelial response. Then there are other lesions which, because of an accumulation of hemosiderin, melanin, the products of fat necrosis, or elastic tissue degeneration, resemble xanthic entities and may be mistaken for them if judged by color alone.

Therefore, any classification of xanthomatous conditions will include a motley group of unrelated lesions. In the following outline an attempt has been made to place these visually similar masses under separate categories.

I *The Pseudoxanthomas* or, Preferably the *Xanthic Granulomas*—These lesions are manifestations of the reticulo-endothelial response to destructive processes resulting in the accumulation of lipoids and blood and are found in:

A Chronic inflammatory foci such as the xanthic granulomas of sinus tracts, chronic cholecystitis or cholangitis, appendix abscess, pyelonephritis or typhlitis.

B Neoplasms that have undergone focal hemorrhage and fat necrosis, such as xanthic granulomas in hypernephromas, sarcomas, adrenal tumor, tumor of the testis or carcinoma of the breast.

C Possible selective response to an unknown irritant and when a metabolic disturbance is not demonstrable such as xanthic granuloma palpebrarum (xanthelasma) or multiple xanthic granulomas.

D Possible response to the repeated pounding such as occurs in the large arteries when cardiac hypertrophy and hypertension are present,⁷ for example, atheroma of the aorta and its tributaries.

II *The Xanthomatoses* or, Preferably the *Xanthic Lipidoses*—These occur as evidence of a reticulo-endothelial response to disturbances in lipid metabolism usually hypercholesteremia. Not infrequently there is an associated blood destruction with hemochromatosis.

A Primary Diffuse xanthic infiltrations resulting from a lipoidosis and based on a constitutional deficiency e. g. 1 Gaucher's disease. Foam cells store kersasin, usually in females acute and chronic forms enlarged spleen. 2 Niemann-Pick's disease—essential lipid histiocytosis, foam cells store phosphatids, neutral fat is absent usually in females splenohepatomegaly. 3 Hand-Schüller-Christian's disease. Foam cells store cholesterol usually in males a chronic disease of the skeleton with the skull predominantly affected by the foam cell infiltrations. 4 Tay-Sachs's amaurotic family idiocy, usually in males, foam cells store phosphatids, are in the ganglions and glia of the leptomeninges in the tela choroidea and in the connective tissue about blood vessels.

B Secondary Xanthic nodules are sometimes seen in some cases of chronic diabetes, hepatic or renal disease associated with a hypercholesteremia. The localization in certain areas (hands, elbows, knees) may represent selective infiltration possibly resulting from local irritation. Examples are xanthoma multiplex, diabeticorum and multiple xanthomatosis.

III *Xanthic Neoplasms*—It is a question whether true foam cell neoplasms (xanthic histiomas or reticulo-endothelioma) occur.

A "Xanthoma" or xanthic fibroma—a benign connective tissue tumor associated with tendon sheaths or about joints. It is made up mainly of giant cells and some foam cells. The former contain blood pigment and as a result the tumor gives a positive iron reaction. It is regarded by some as a fibroma with a secondary xanthic response (xanthic fibroma). The giant cell tumors of the bone marrow and gums may also contain foam cells.

B Lipoid storage rarely occurring in neoplastic cells whose mother cells physiologically contain fat (possibly a local dyslipoidism). Xanthocarcinoma of the prostate and adrenal, xanthome en tumeur of skin and mucous membranes.

IV *Lesions Simulating Xanthic Entities Because of Similarity in Color*—A Pseudoxanthoma elasticum (subcutaneous degeneration of elastic tissue).

B Traumatic fat necrosis of breast and the like.

C Fibrohemangioma.

D Hemorrhagic bursitis.

E Hemorrhage in a lipoma, myxoma or fibromyxoma.

F Melanotic tumors.

The four cases that follow are examples of xanthic lesions.

The first case is that of a markedly infected kidney which, because of the yellow masses that it contained, was diagnosed at operation as a hypernephroma. Microscopic investigation, however, revealed that the golden-yellow nodulations about the pelvis and in the parenchyma (figs 1 and 2) were composed entirely of foam cells. The kidney was diffusely inflamed and the peripelvic fat was infiltrated and necrotic. This case is an example of a generalized xanthic granulomatosis of the kidney secondary to infection. A similar condition

Fig. 2 (case 1)—High power magnification through cross section of a xanthic nodule from kidney showing foam cells.

developed in a patient with pyelonephritis, which was superimposed on a "spinal bladder" following fracture of the first and second lumbar vertebrae (fig 3).

The third case is that of a partially resected thickened ascending colon containing orange-yellow nodules. The mass was looked on as neoplastic. It communicated with a yellow sinus tract, which led to the lower pole of the right kidney and from which an "orange-colored pus" exuded. A review of the microscopic sections of the yellowish nodules showed that they were made up of "foam cells." This is an example of a xanthic granuloma associated with a typhlitis and a sinus tract, which probably arose in an infected kidney.

The last case is that of a prostate removed as an obstructing benign hypertrophy but which on section was found to contain a golden-yellow infiltration. The microscopic sections (fig 4) revealed a carcinoma with foam cells lining the pseudo-alveoli and containing lipid granules when stained with sudan III. This is an example of xanthocarcinoma.

REPORT OF CASES

CASE 1—History—V G, a man aged 31, a Negro, admitted to the Squier Urological Clinic, Dec 30, 1932, had had, nine years before an attack of severe pain in the right lumbar region, which radiated anteriorly and was accompanied by hematuria. Palliative therapy by his local physician gave relief. Three years later the pain recurred without hematuria. Nine months before admission the lumbar pain returned and became steadily worse. For four months he had chills and fever, the urine became cloudy and a feeling of soreness developed over the right kidney region anteriorly. He lost 17 pounds (7.7 Kg) in five months. Nine months before admission he had an attack of pneumonia.

Examination—There was evidence of an unresolved pneumonia at the left base posteriorly. The patient had marked tenderness in the right lumbar and right kidney region anteriorly. There were no palpable masses. The prostate was small, firm, irregular and tender. The blood pressure was 102 systolic, 70 diastolic.

The Wassermann reaction was negative. The urine was cloudy and acid, with a specific gravity of 1.020 and a heavy trace of albumin. It was negative for sugar and diacetic acid.

Fig. 3 (case 2)—Cross section through xanthic area of kidney.

The sediment contained pus and an occasional red blood cell. Hemoglobin was 60 per cent (Dare), red blood cells numbered 3,580,000, white blood cells 15,350, polymorphonuclear leukocytes 94 per cent, eosinophils 1 per cent, mononuclears, 5 per cent. The blood urea was 147 mg and the blood sugar 100 mg per hundred cubic centimeters.

Roentgen studies showed resolving pneumonia of the right lower lung and a small amount of fluid in the pleural cavity. There was a calcified shadow in the right lower ureter, also shadows suggesting prostatic calculi.

A cystoscopy, December 31, revealed that the bladder was diffusely inflamed. The right ureteral orifice exuded pus and blocked the ureteral catheter 1 cm from the opening. The flow of urine from the left side was clear, intermittent and negative for tubercle bacilli, white blood cells or red blood cells. It contained 0.5 mg of urea per hundred cubic centimeters. Indigo carmine appeared in three minutes from the left kidney, and the concentration was excellent. None appeared from the right side. The roentgenograms revealed that there was no catheter up the right ureter. The calcified shadow occupied the same relative position in the lower right ureter as in the previous report. The right kidney was enlarged. The left pyelogram was negative.

The provisional diagnosis was calculus of the right lower ureter, right pyonephrosis.

Operation and Result—Jan 4, 1933, a right ureterolithotomy was performed by Dr. George Cahill. The ureter was found to be thickened, firm and dilated. A small hard nodule was felt just above the intramural portion. A linear incision was made over it, and a small triangular calculus was removed. Removal was followed by a profuse extravasation of thick, yellow, foul-smelling, purulent material. Two cigaret drains were inserted, and a standard closure was made. The calculus was a yellow-gray and measured 1 by 0.75 by 0.5 cm.

The patient had an uneventful recovery but the wound would not heal and continued to drain a large amount of pus. A cystoscopy was performed, January 25, and a catheter was passed to the right renal pelvis without obstruction. Pure pus came from that side. From 20 to 30 cc of this purulent fluid was aspirated. A right pyelogram was made. The roentgenogram revealed that the pelvis was well filled and appreciably dilated. There was an irregularity in density and mottling of the dye in the calyx, which suggested the presence of inspissated purulent material. The diagnosis was right pyonephrosis.

January 20 an intravenous urography was performed with diodrast and revealed in the immediate film that the left kidney pelvis was quite well filled and not dilated, but there was no evidence of dye in the right kidney pelvis. The fifteen minute film was the same as the preceding. In the seventy-five minute film a partial emptying of the left kidney pelvis was seen. There was no evidence of any dye in the right kidney pelvis.

January 27 a complete nephrectomy was performed by Dr. J. B. Squier on what was considered a pyonephrotic non-functioning kidney. At the operation the kidney was found to be adherent to the surrounding fatty tissue and was with difficulty separated from it. The surface was normal except for small pale yellow thick firm areas in the cortex and in the pelvic fat. The yellow was striking and stood out from the surrounding tissue remarkably. The general impression was that one was dealing here with a hypernephroma of the kidney.

Pathologic Examination—The specimen consisted of a right kidney (fig. 1), pinkish-gray measuring 12 by 6 by 4 cm and showing a thin adherent capsule and a fairly regular contour. The posterior surface had attached to it a somewhat irregular, smooth, dull yellow firm tissue measuring 4 by 2.5 cm. It had somewhat the appearance of adrenal tissue. However, a similar type of tissue but only 1 cm in length was noted on the anterior surface. Lateral to the mass of yellow tissue was a small rounded, smooth opening entering one of the calices of the kidney. On cross-section the pelvis and calices were dilated. The small areas of yellow tissue described on the outer surface were scattered throughout the calices and cortex. The cortex and medulla were in the proportion of 1:1 and 1:2 respectively. The tissue was interesting from both a macroscopic and a microscopic point of view (fig. 2). The renal tissue in the sections was so filled with chronic inflammatory cells, hyalinized and fibrous tissue that it was barely recognizable. Of particular interest were sections through the yellow areas in the cortex. These were filled with foam cells (xanthomatous areas) and fatty degeneration. Intermingled with the foam cells were fibrous strands and chronic inflammatory cells and many red blood cells. The surrounding tissue was fibrous and in places hyalinized. There was practically no functioning renal tissue in the vicinity of the fatty degeneration. Many large endothelial cells infiltrated the infected tissue. Calcium salts were deposited in a few areas. There was no evidence of a malignant condition. There were degenerative as well as regenerative phases of fat necrosis and even though there was no evidence of giant cells this tissue may be classed under the degenerative phase of fat necrosis.

The diagnosis was xanthomatosis of the kidney, pyelonephritis.

CASE 2—History—T G, a man aged 27, admitted to the Squier Urological Clinic April 9, 1934, had sustained a compression fracture of the first and second lumbar vertebrae with displacement of the fourth lumbar vertebra following a fall twenty months before. The temporary muscle paralysis gradually cleared. He was unable to void urine from the start.

Six weeks after the fall a suprapubic drain was inserted and the suprapubic sinus remained patent to date. He was observed in the ward for a time, and evidence of a right pyelonephritis developed.

Examination—The Wassermann test with the alcoholic and cholesterin antigens was negative. Lumbar puncture was negative except for an increase in globulin and albumin. Hemoglobin was 95 per cent, the red blood cells numbered 5 090 000 and the white blood cells 12,450, polymorphonuclear leukocytes, 75 per cent lymphocytes, 15 per cent, eosinophils, 3 per cent, myelocytes 1 per cent and mononuclear leukocytes, 6 per cent. The urine contained albumin and was alkaline and full of calcium oxalate and triple phosphate crystals. Microscopic examination showed mucus and pus. Smears for tuberculosis were negative.

Roentgenograms of the dorsal and lumbar spine showed narrowing of the body of the first lumbar and fusion between the twelfth dorsal and first lumbar vertebrae. There was a slight scoliosis of the upper dorsal with a concavity to the left and a slight scoliosis of the lower lumbar with a concavity to the right. Roentgenograms of the heart and lungs were negative. A ureterogram showed the left ureteral catheter at the level of the kidney pelvis and the right at the level of the transverse process of the third lumbar vertebra. The right kidney shadow was normal in size, shape and position. There was a distortion of the right kidney pelvis, which may be due to tuberculosis, and in addition there was a sinus extending along the course of the psoas muscle and connecting with the kidney pelvis. The diagnosis was rupture of the left kidney (?).

Blood sugar was 0.92 per hundred cubic centimeters and blood cholesterol, 177 mg per hundred cubic centimeters.

Operation and Result—June 20 Drs. Fish and Squier performed an intracapsular nephrectomy. Gas, oxygen and ether were used. A right lumbar incision was made and the kidney exposed, it was freed with difficulty because of a marked inflammatory reaction around it. A rubber catheter was inserted round the pedicle and tied to control its position and thus lessen the danger of hemorrhage. Sutures were then applied around the pedicle, and the kidney was removed. Two cigaret drains were inserted and the standard closure was made.

Pathologic Examination—The kidney was small, measuring 7.5 by 3.5 by 2.5 cm. The surface was coarsely lobulated and covered with punctate hemorrhages. The capsule was absent. A cross section through the pelvis lengthwise revealed a moderately dilated pelvis and blunted calices. The greater portion of the pelvic mucosa had been torn away during the operation, and what remained was diffusely red and granular. In the minor calices were plugs of blood clot. The kidney proper showed a diminished cortex. The medulla was thickened. The entire surface, by its pale glistening color suggested a marked increase in fibrous tissue. The striking feature was the presence about the calices and in the stroma of orange-yellow nodules. These varied from 0.5 by 0.5 cm to 1.3 by 1.0 cm. There were about eight in this particular level and all presented a remarkable picture. Microscopically (fig 3) the kidney was the seat of a massive diffuse lymphocytic infiltration. Tubules and glomeruli were equally engulfed by this process. In places liquefaction necrosis had occurred and tiny abscesses were present. Fibrosis and hyalinization of glomeruli, converting them into huge pink staining amorphous islands in a sea of lymphocytes produced a striking effect. The tubules were disrupted, some contained fibrinous casts. Cross sections near the pelvis showed in addition to the lymphocytic invasion a marked hemorrhagic tendency and areas filled with foam cells. These cells were large and finely vacuolated spaces in the cytoplasm suggested that they were filled with phagocytized lipids which had been dissolved in the process of preparation.

The final diagnosis was xanthomatosis of the kidney, pyelonephrosis, chronic suppurative pyelonephritis, abscesses in the kidney, hemorrhage in the kidney and fibrosis in the kidney.

CASE 3—History—L. O., an American housewife aged 44, admitted to the Presbyterian Hospital complained of pain in the right side of the abdomen, distention and vomiting which had lasted for three weeks. Two days before admission retention of urine developed. Her physician gave her an injection

of morphine, following which the abdominal pain subsided, she passed a large quantity of urine and the abdomen became smaller.

On admission she presented a nontender mass to the right of the umbilicus. It became more definite by pressing forward in the flank and moved slightly with respiration. After several days of observation the mass decreased and became barely palpable.

Roentgenographic studies of the abdomen showed a shadow superimposed on the right kidney and of almost the same density as the kidney. A barium colon enema indicated a slight filling defect of the ascending colon just below the hepatic flexure. Cystoscopy and pyelographic studies were negative.

The temperature ranged from 98.6 F and the pulse was 78 and the respiration rate 20 per minute. The blood Wassermann reaction was negative. The blood urea was 1.36 mg per hundred cubic centimeters. The stool examination was negative for blood. The urine was clear, acid and amber with a specific gravity of 1.026, there was no albumin or dextrose. The microscope revealed a few white blood cells and epithelial cells.

Fig 4 (case 4)—High power magnification through xanthocarcinoma of prostate showing malignant pseudo-alveoli whose cells contain lipid droplets which were stained with scarlet red.

Operation and Result—The patient was operated on by Dr. A. O. Whipple. The diagnosis before operation was carcinoma of the ascending colon. The ascending colon was attached to the lateral abdominal wall for a distance of 3 cm but was easily separated from it. Corresponding with this area and partially encircling the wall of the colon was a hard mass in which yellowish nodules were seen. An ileocolostomy was done and the ascending colon and ileum were removed. When the resected mass was lifted out a peculiar orange-colored thick pus was seen to exude from a tubular structure, which opened in its bed. A probe passed easily for a distance of from 12 to 15 cm to the pole of the right kidney where a grating and calcareous click was noted. Since it was not wished to prolong the operation a nephrectomy was not done. The kidney region was drained by means of counterdrainage in the flank. The gallbladder was normal. The postoperative diagnosis was chronic pericolicitis and chronic ureteritis.

Pathologic Examination—The specimen consisted of a cecum, an appendix and a short portion of ileum and ascending colon.

There was a firm, irregular nodular mass on the lateral aspect of the ascending colon, 13 cm from the fundus of the cecum. The appendix was small and embedded in an exceedingly fat mesentery. On section the appendix lumen was obliterated, and the cecum contained formed feces. The ileocolic valve was surrounded by two thick, rounded ridges, presenting a slitlike opening. The wall of the ascending colon was moderately thickened at the site of the dense mass described. A dark brown nodule, 1 by 0.3 cm, projected into the lumen of the intestine. Section through the larger mass showed a relatively dense tissue having a mottled appearance, some areas appearing white and fibrous while others were a bright yellow brown. Section through the ascending colon showed a distorted hemorrhagic mucosa, and connective tissue and smooth muscle the structure of which was massed by a dense infiltration of mononuclear leukocytes. There was no evidence of tuberculosis or neoplasm. Scattered throughout were accumulations of foam cells with the appearance characteristic of a xanthomatous infiltration.

The final diagnosis was xanthomatous infiltrations, chronic pericolitis and chronic ureteritis.

CASE 4—History—J. G., a man, admitted to the Squier Urological Clinic Oct. 27, 1933, had had repeated attacks of swelling of the left testicle over a period of six months, and frequency, urgency, and nocturia (six times) with incontinence over a period of two years. He had catheterized himself twice a day for six months. He lost 28 pounds (12.7 Kg.) in eight months. The past history was negative except for gonorrhea which he had contracted fifty years before.

Examination—The patient was well nourished. The blood pressure was 122 systolic, 90 diastolic. The abdomen was tender in the left lumbar region anteriorly. The liver edge was palpable. The left testis was enlarged and the epididymis indurated and tender. The residual urine was 75 cc., it was cloudy and contained many pus cells. The prostate was enlarged, firm, smooth and movable. Cystoscopy revealed a trabeculated bladder, cystitis and a bilobed prostatic intrusion.

The blood urea was 22.4 mg. and the blood sugar 105 mg. per hundred cubic centimeters. The red blood cells numbered 4,670,000 with hemoglobin 80 per cent (Dare), the white blood cells numbered 9,000, polymorphonuclear leukocytes 67 per cent, lymphocytes 28 per cent, eosinophils, 2 per cent, mononuclears 3 per cent. The blood Wassermann and Kahn tests were negative.

Roentgenograms of the chest showed increased pulmonary markings throughout both lung fields, a calcified shadow in the lateral portion of the first interspace, which did not have the typical appearance of either a healed acid-fast or a metastatic lesion. Smooth diaphragms, a moderately enlarged aorta and a heart within normal limits. Of the upper genito-urinary tract both kidney shadows were normal in size, shape and position. There was an oval shadow between the tips of the second and the third transverse lumbar process, which lay perpendicular to the axis of the ureter. It did not have the typical appearance of a calculus. It would, however, have to be ruled out. There was no evidence of calculi in either kidney or upper ureter. There was a progressive arthritis of the upper dorsal and lumbar spine. The lower genito-urinary tract showed no evidence of calculi or metastatic lesions or bony pathologic changes.

The preoperative diagnosis was hypertrophy of the prostate.

Operation and Result—October 30 a suprapubic prostatectomy was performed by Dr. George Fish with nitrous oxide-oxygen and ether anesthesia. The bladder retractor revealed a three-lobed prostatic hypertrophy, which was enucleated by blunt dissection. The average amount of hemorrhage followed. Drainage was instituted by a Freyer tube sewn into the bladder, and a cigarette drain placed in the space of Retzius.

The postoperative diagnosis was tumor of the prostate, type unknown.

The patient went into shock and anuria developed. He died fourteen hours after operation in spite of transfusion and an infusion of dextrose.

Pathologic Examination—The specimen consisted of a large bilobed prostate measuring 5.5 by 2.5 by 4 cm. The surface presented a pinkish gray as well as a dull, diffuse yellowish

appearance. This tissue was firm. On cut surface it presented a smooth, firm, dull and dirty yellowish appearance. This tissue was in places infiltrating the fibro-adenomatous tissue. Sections that had come from the lateral lobes showed a glandular increase characteristic of the so-called benign hypertrophy of the prostate. The numerous acini were dilated in spots and closely crowded in others. They were then lined by a simple columnar epithelium. Numerous prostatic concretions were seen as well as granular debris and desquamated cells. The fibromuscular elements were abundant and in one area they predominated, giving the impression of a fibromyxomatous nodule. The sections that corresponded with the yellow areas ("capsules") showed the presence of a carcinoma. This carcinoma was unusual because of (1) the presence of lipid granules in the epithelium lining many of the pseudo-alveoli, and (2) the relative infrequency of mitotic figures for a neoplasm of such marked activity as the intense proliferation of the cells indicated. Most of the constituent cells were small and ovoid, with round nuclei and eccentric nucleoli. Enormous grapelike clusters of these cells filled the region of the "capsule" (probably really the false capsule or old gland of the prostate or possibly the posterior lobe), and in one area the mass had broken through and engulfed the neighboring benign looking acini. Interspersed were acini, some or all of whose lining epithelial cells were enlarged and resembled "foam cells." A scarlet red stain showed the presence of red granules—lipoid, probably cholesterol (fig. 4).

The final diagnosis was fibro-adenoma of the prostate, lateral lobes, carcinoma of the prostate, with xanthomatous changes.

SUMMARY AND CONCLUSIONS

1 The reticulo-endothelial system is important as an entity and as a mechanism responding to accumulations or excess of lipoids and particulate matter.

2 Accumulations of lipoids may result from inflammatory, traumatic or deficiency causes.

3 The lipophagic response by cells of the reticulo-endothelial system results in the formation of a xanthic mass.

4 The cell unit of the xanthic mass is the foam cell. The foaminess results from the solution of cell lipoids during the routine process of preparation. Should scarlet red be used, the lipoids then appear as red, intracellular droplets.

5 The orange color of a xanthic mass is due mainly to a combination of its lipoids and lipid pigment content and to a lesser degree to its blood pigment.

6 An outline of xanthic entities, which has been included, embraces the xanthic granulomas, the xanthic lipoidoses and the so-called xanthoma and calls attention to lesions that resemble them in color but are basically different.

7 In two cases, unusually extensive "xanthomatosis" of the kidney was present, and in one case a seemingly similar condition was found in a carcinoma of the prostate.

911 Park Avenue.

Language and the Human Mind—Language as heard and spoken long preceded civilization, and has been recorded as cuneiform and hieroglyphic writing by the early civilizations of Mesopotamia and Egypt, and much earlier as crude pictorial representations. In one form or another language has exerted such a powerful influence on the evolution of mind in man and is so intimately associated with this that it causes no surprise that the one is so commonly regarded as the equivalent of the other. This, however, is by no means the case, language being merely the symbolical instrument of mind and not its compeer, although in some form or equivalent it is indispensable for the full evolution of the complex cerebral changes whose final end is individually acquired skilled psychomotor activity.—Bolton J. S. *The Evolution of Mind* *Lancet* 1:728 (March 30) 1935

GLOMUS TUMORS

(ARTERIAL ANGIONEUROMYOMA OF MASSON)

DEAN LEWIS, M.D.

AND

CHARLES F. GESCHICKTER, M.D.

BALTIMORE

In the Laboratory of Surgical Pathology of Johns Hopkins Hospital is a tumor that was removed from the end of the little finger of the right hand in November 1924. This tumor, it is stated in the history, had no definite capsule. It was regarded as a neurofibroma but the epithelioid cells and the vascular spaces in it could not be satisfactorily interpreted.

CASE 1—The patient from whom this tumor was removed was a white woman, aged 38. Eight years before the tumor was removed the patient experienced severe, sharp pain in the tip of the little finger of the right hand. Five years later, that is three years before removal, an incision was made and a curettage performed as a diagnosis of periostitis ("a bone bruise") had been made. After this operation a distinct tumor was discovered. The tumor was very painful when pressed on and definite painful sensations were experienced with alterations in temperature from heat to cold and vice versa. A small mass could be palpated beneath the skin on the palmar surface of the terminal phalanx of the little finger. To the ulnar side of the tumor could be seen the scar of the former operation.

As stated in the history, a histologic diagnosis of the tumor was not made. The vascular space and the groups of epithelioid cells raised some doubt as to the diagnosis and at that time no interpretation of their character was attempted.

The following three cases presented tumors histologically like the one just referred to.

CASE 2—A white man aged 67 recently admitted to the surgical clinic, complained of severe, often excruciating pain about the left knee which radiated into the thigh and leg. The pain was thought to be a sequela of a fracture sustained many years before. An operation had been performed to correct the displacement.

On examination a small tumor approximately the size of a lima bean was found just in front of the middle of the patella on the left side. The patient experienced excruciating pain when pressure was made on the tumor, even when it was struck by the end of his overcoat or rubbed by his trousers. Shortly before entering the hospital the patient's wife accidentally dropped a newspaper on the tumor. Even this insult caused excruciating pain. This small tumor was freely movable, somewhat irregular in shape and as stated extremely painful. The skin covering the tumor seemed normal. The tumor was excised under local anesthesia.

Microscopic examination revealed many blood spaces between which were epithelioid cells. Histologically this tumor was much like the one in case 1 removed in 1924; the histologic diagnosis of which was not definitely made.

CASE 3—A white woman aged 67 had noted a small mass just below the right elbow a little to the outer side for fifteen years. During the past five years the mass had not increased in size. The mass had been extremely painful for the past nine months and pressure on the mass would cause paroxysms of pain. The tumor was removed under local anesthesia in September 1930. It was located just beneath the skin and embedded in the fat. It was composed of soft, spongy red tissue like that of an angioma and was surrounded by fibromyxomatous tissue. At operation it was thought to be an angioma; the preoperative diagnosis had been neurinoma. There has been no recurrence of this tumor.

Histologically there were areas which resembled those of cavernous hemangioma and between these were epithelial-like

cells which resembled those seen in a melanoma. Nerve fibers were found in the tumor, which was surrounded by a fibrous capsule.

CASE 4—A white woman, aged 38 for three years prior to 1929 had had pain in the end of the right thumb. A diagnosis of a felon was made, and the thumb was lanced several times in the spring of 1929. In the fall of that year a roentgenogram revealed a dark shadow over the bone. The terminal phalanx was exposed and curetted and drains were kept in place for the next two weeks. In November 1930 the patient entered a hospital where the diagnosis of Ewing's tumor was made from the tissue removed at that time. The thumb and the axilla were irradiated. The patient then returned home, where she received a second course of roentgen treatments in 1931, the thumb and axilla being irradiated. In 1932 she returned to the hospital and the thumb and axilla were again irradiated. Following this a slight swelling of the thumb and axilla, accompanied by pain developed. She returned home and received a fourth course of irradiation in November 1932. The family had been notified that the case was hopeless.

When seen by us nothing could be palpated in the axilla except what seemed to be fat, probably altered by the roentgen exposure. The hand and chest were normal.

Fig. 1—Glomus tumor in a woman aged 67. This tumor had been noted for fifteen years. There was no increase in size over a period of five years. Nine months before removal the tumor had become extremely painful. Pressure on the tumor caused excruciating paroxysms of pain.

The sections that had previously been made were examined and a diagnosis of a benign glomus tumor was made. The patient returned home and when last seen in 1934 she was well. Recent word indicates that she has continued to be well.

These four histories have been given in some detail, for in them are related the symptoms associated with tumors described by Masson in 1924 as glomus tumors or arterial angioneuromyomas. The name glomus was applied by Masson because of the histologic likeness of these tumors to the glomus coccygeum of Luschka. He described three such growths, one in the forearm, two in the thigh which had a definite and characteristic structure. Masson thought that the like clinical symptoms warranted him in concluding that he was dealing with a new type of tumor—a morbid entity. In 1925 Martin and Dechaume reported two cases that were identical histologically with those described by Masson. It was thought that these tumors developed from the arterial glomus which is considered a normal organ. The development from the glomus accounts for the

frequent subungual location. As will be seen from the histories, such tumors may occur in other locations.

The majority of the cells forming the glomus resemble epithelial cells. The nuclei are large and round and contain a nucleolus. The chromatin stains with only average intensity. The protoplasm is acidophilic. These cells are found in the neighborhood of blood vessels, and in places they seem to have a circular arrangement

Fig. 2—Cross section of a glomus tumor removed from in front of the left patella. The capsule, angiomalike spaces and epithelioid cells distributed between the blood spaces may be seen.

and are distinguished with difficulty from the smooth muscle fibers. These cells, resembling epithelium, are polygonal and clear. The cells surround the vessels in areas almost like endothelium and are separated by just a thin layer of collagen fibers.

Popoff¹ has recently described a peripheral arteriovenous anastomosis. We shall refer to this frequently in discussing the origin and microscopic changes of the tumors under discussion. Sucquet was apparently the first to describe peculiar vessels in several regions of the palm and sole, especially in the midzone on the ventral surface of the fingers and toes, which were larger than the ordinary capillaries and emptied directly into veins without an intervening capillary network. According to Popoff, these arteriovenous anastomoses are found almost exclusively over the ventral surface of the hand and foot. They are constantly present in the region of the nail bed and in the tips of the digits, the palmar surface of the first, second and third phalanges, and the thenar and hypothenar eminences of the hand. A like distribution is found in the foot, but they are also found about the heel. The anastomosis is usually S shape, twisting and coiling, seldom straight.

The histologic picture of the anastomosis is repeated in the tumor. The lumens are usually narrow and irregular. The endothelial cells are large and cuboidal and arranged in two or three rows. The muscular coat of the vessels is composed of an inner longitudinal and

an outer circular layer, but these are indistinct. Among the muscle cells are large, clear, epithelioid cells with oval or globular nuclei that have little chromatin. Ramifying among these cells are anastomosing cells with elongated nuclei and transparent cytoplasm without myofibrils. The outer zone of the arteriovenous anastomosis is made up of loose, delicate, collagenic reticulum, in which may be found many nonmedullated nerve fibers. The anastomosis is surrounded by coarse lamellated, collagenic tissue, in which are found the collecting veins.

It is suggested by Masson, Popoff and others that the glomus controls the arteriovenous circulation in the digits and aids in regulating both the local and the general body temperature.

The histologic appearance of glomus tumors is indicated by the accompanying photomicrographs. Figure 2 shows under low power a cross section of such a tumor. In this are shown the capsule made up of rather heavy connective tissue fibers, the blood spaces resembling those of a cavernous angioma, and the epithelioid cells, which are distributed throughout the tumor. Scattered throughout are nerve fibers. Figures 2 and 3 indicate the cellular characteristics and appearances better than any written description.

The glomus tumor, as has already been implied, occurs most frequently in the nail bed and about the fingers and toes—in those places in which the glomus occurs with greatest frequency and abundance. They are by no means limited to these areas, however, for

Fig. 3—Section showing characteristics of the cells found in glomus tumors. These cells form a mantle for some of the vascular spaces.

thirteen of the seventeen cases that we have observed have developed in other locations, such as the elbow, the knee, the leg and the palm of the hand.

Clinically the most striking characteristic of the glomus tumor is pain, spontaneous and provoked. The pain is excruciating at times. Pain of such severity is not found in a neurinoma. These tumors usually are smaller than the neurinoma and are not situated on a

large peripheral nerve. When these occur in the nail bed they usually have a cyanotic appearance, which is almost pathognomonic. In some instances vasomotor disturbances are quite marked. A glomus tumor should always be looked for when the patient experiences severe pain in the hand over a long period. The nature of the lesion should be suspected when a tumor that is excruciatingly painful occurs in other regions and

Fig. 4—Cross section of a glomus tumor under a higher magnification than shown in figure 2

reacts by pain to pressure or touching much like the trigger zone in tic douloureux. In the hands a marked atrophy may develop. This is the atrophy of disuse because any motion may bring on a paroxysm of pain.

A mistaken diagnosis is not infrequently made in such cases. The diagnoses probably most frequently made are endothelioma and angiosarcoma. At times these tumors, which are encapsulated and benign, are regarded as malignant.

A short summary follows of the remaining thirteen cases that we have studied.

CASE 5—A white man aged 65, had a tumor situated on the forearm. The tumor was removed elsewhere and sent to the hospital for diagnosis. A microscopic diagnosis of peripheral angiosarcoma had been made. The patient was well five years after local removal. The histologic diagnosis made in the laboratory of the Johns Hopkins Hospital was glomus tumor.

CASE 6—A white man aged 47 had noticed a small mass about the size of a pea on the right thigh just above and internal to the great trochanter. This small tumor had caused pain and was tender. Nine years before the tumor was removed it had been lanced. The tumor had gradually increased in size and was painful. It was removed in November 1909.

CASE 7—A white woman aged 30 had noticed a small mass under the skin of the thigh three months before she was seen. This tumor was painful (spontaneous and provoked) but not excruciating. In May 1933 the tumor was removed. It proved on section to be a typical glomus tumor.

CASE 8—A physician stated that he had noticed for many years a small tumor on the anterior aspect of his right leg. Thus he believed followed trauma. During the past year he noticed a slight increase in the size of the tumor. The tumor was removed in May 1926, a wide margin being given the tumor. The tumor seemed to be of the angiomatous type. The large epithelioid cells found in the tumor were thought to indicate malignancy. The patient was reported well in 1928 two years later.

CASE 9—A white man, aged 57, had a small tumor removed from the subcutaneous tissue about the knee. The growth was definitely encapsulated and thought to be a hemangioma. Histologically the tumor was typical of the glomus group. It was sent to the laboratory for diagnosis because the cells surrounding and between the vascular spaces had caused some confusion.

CASE 10—A graduate nurse had a tumor in the palm of the hand. The small tumor was exceedingly painful. When examined histologically after removal it proved to be a typical glomus tumor.

CASE 11—A Negro aged 48 had a small growth on the flexor surface of the left arm near the elbow. When first noted it was the size of a pinhead, but it gradually and very slowly increased in size. Dull pain was felt in the arm all the time. This was aggravated by motion or by striking the tumor. The tumor when it was removed measured 2 cm in diameter.

CASE 12—A white woman aged 60, complained of pain in the finger, almost constant of fifteen years duration. There were practically no physical changes except slight edema. There was marked pulsation on the inner border of the index finger. A definite tumor was palpated here. There was a

Fig. 5—Epithelioid cells of a glomus tumor

lipoma on the dorsum of the right foot. The tumor on the finger was excised and on microscopic examination showed typical angiomatous spaces surrounded by epithelioid cells.

CASE 13—A white man aged 29, a draftsman, had fallen six years before and injured his left elbow. A small bluish sensitive tumor appeared on the left forearm about 2 inches from the tip of the olecranon. This was removed after about three years of slow growth but recurred and gradually increased until it was the size of a large pea. It was painful when he rested his arm on the drawing boards. Examination

revealed a tumor about 8 mm in diameter, apparently a hemangioma mass near the left elbow. The tumor was excised under local anesthesia and proved to be definitely encapsulated.

CASE 14—A white man had had a mass on his left wrist for the past eight years. He had no pain except when attempting to lift heavy things. The mass was freely movable, round, well circumscribed cystic, and the size of a walnut. The mass was excised. The specimen consisted of an oval skin flap 3 cm long and 1.5 cm in maximum diameter, excised with the underlying tissue for a distance of 2 mm. Lying directly beneath the skin a rounded, soft, circumscribed mass was found, which measured 1.5 cm in diameter and 8 mm in thickness. The mass lay directly beneath the epidermis. It was encapsulated and the capsule has been shelled out from the underlying tissues.

CASE 15—A white man aged 80 had a tumor removed from the dorsal surface of the hand, between the index and middle fingers. The tumor was excised and the material sent to the laboratory for microscopic examination. No further clinical data are available.

CASE 16—A white man aged 51 seen in the dispensary, April 12, 1935, was diagnosed as having syphilis with involvement of the central nervous system, cardiac insufficiency and first degree heart block. During the examination a small bluish mass the size of a large lima bean was discovered on the extensor surface of the right elbow. The mass was freely movable and extremely painful when touched or pressed on.

Fig. 6—Relation of the epithelioid cells to the blood spaces in the tumor.

The mass appeared about twelve years before and grew to the present size in two years. It had gradually become more tender. The patient was frequently awakened at night because of pain that was caused when the mass was rubbed by the bed or night clothing. A diagnosis of a glomus tumor was made. The patient was referred to the division of surgery and the mass was removed. Extreme pain was complained of when an attempt was made to inject procaine hydrochloride. On histologic examination the tumor was found to have the typical structure of a glomus.

CASE 17—A white woman aged 24 was examined because of a painful, bluish tumor beneath the right thumb nail about 1 mm in diameter. The pain had been present for one month

and had been more severe for the past two weeks, extending up the arm to the shoulder. The overlying nail was slightly irregular. A roentgenogram made of the distal phalanx of the thumb showed a minute area of rarefaction beneath the tumor site. The tumor was excised together with the entire nail and the surrounding soft parts. It was in contact with the nail above and the bone beneath. On gross examination it was found to be circumscribed and was about 2 mm in diameter. From frozen sections made at the time of operation it was thought to be a round cell sarcoma of the Ewing type, and post-operative irradiation was given. Examination of a permanent section showed a typical glomus tumor, with numerous capillary spaces surrounded by epithelioid cells. The patient has remained well now more than five years.

THERAPEUTIC RESULTS WITH THE KETOGENIC DIET IN URINARY INFECTIONS

HENRY F. HELMHOLZ, M.D.
ROCHESTER, MINN.

The successful use of the ketogenic diet in the treatment of urinary infections is dependent on the bactericidal action of beta-oxylbutyric acid at a certain degree of acidity. The limit at which this action occurs has been shown to be 0.5 per cent beta-oxylbutyric acid and a pH of below 5.5. An increase in the concentration of the acid and a decrease in the pH increase the bactericidal power of the urine. In like manner, it has been shown that bactericidal action occurred below the minimal concentration when the pH of the urine was lowered and that bactericidal action was present at a pH above 5.5 when the concentration of the beta-oxylbutyric acid was increased considerably. At a pH of 5.7 a concentration of 1.8 per cent beta-oxylbutyric acid showed a bactericidal action, and at a pH of 5.0 a concentration of 0.4 per cent acted similarly.¹ It has been demonstrated by Osterberg and Helmholtz² that the necessary concentration of beta-oxylbutyric acid can be determined by a relatively simple method. By means of chlorophenol red paper a pH below 5.5 can be estimated.

It has been said that the ketogenic diet kills the colon bacillus more readily than it does other members of this group.³ Clinically, in my experience, it has proved true that the colon bacillus usually was the first organism to disappear from the urine when more than one organism was present. In a series of cases in which the urinary tract was infected with *Escherichia coli*, *Aerobacter aerogenes*, *Proteus vulgaris*, *Staphylococcus*, *Streptococcus* and *Pseudomonas*, the diet has acted very satisfactorily. Similar results have been obtained in experiments in vitro with these organisms. That with one organism the infection is more deeply seated than with another, so that the former organism cannot be acted on as successfully as the latter is quite possible.

Knowing what conditions must be achieved before bactericidal action is possible, it becomes a question if, and how readily, these conditions can be achieved in cases of urinary infection.

The formation of the ketone bodies is dependent on the inability of the body to oxidize large amounts of fat in the absence of available carbohydrate. It becomes necessary, therefore, to feed patients large amounts of fat and very small amounts of carbohydrate. Some few children do not tolerate these large amounts of fat. They suffer from digestive disturbances and are not able to continue with the diet. Others, again, seem

Fig. 1—Bilateral hydronephrosis with megalo-ureter on left side

to have no difficulty in retaining the diet but do not seem to absorb the necessary amounts of fat to produce a good ketosis. The urine of two infants who received a diet in which the ketogenic-antiketogenic ratio was respectively 4:1 and 5:1 showed at no time a p_H below 5.7 or more than 0.1 per cent beta-oxybutyric acid. Large amounts of fat were found in the stools.

The greatest difficulties were encountered in the cases in which renal function was decreased. The diseased kidneys were unable to excrete a urine that had a low p_H and a high

concentration of beta-oxybutyric acid. In cases in which urine has been obtained separately from the two kidneys the urine that was obtained from the kidney which was more severely damaged was more alkaline and contained less beta-oxybutyric acid than did the urine that was obtained from the other kidney. In cases in which the value for the urea was more than 50 mg per hundred cubic centimeters of blood, the patients seem to have difficulty in excreting a urine that has a high concentration of beta-oxybutyric acid.

Stones that remain in place also seem to be an absolute obstacle to successful treatment of a urinary infection. In one case in which bilateral renal calculi had been removed two small stones again developed on one side. In spite of the adequate ketosis and a low p_H the urine from the kidney with the pelvic stones always remained loaded with bacteria.

The ketogenic diet in childhood is to be reserved for infections that do not respond to simple therapeutic procedures. To treat every child who has an acute urinary infection with the ketogenic diet would be entirely unnecessary. The majority get well and the urine becomes sterile with the usual alkalization and forcing of fluids. In some cases it later may be necessary to give ammonium chloride and methenamine for a short time. A small group remains in which there is no obstruction of the urinary tract but in which the infection becomes chronic in spite of the usual types of treatment. The infection will usually clear up promptly as a result of administration of the ketogenic diet.

URINARY INFECTION WITHOUT OBSTRUCTION

I have tried out the ketogenic diet in a series of twenty-four cases of infection of the urinary tract without obstruction. In some of these cases the infection probably would have been cleared up just as readily

by other means as it was with the diet but in order to test out the efficacy of this new mode of treatment the dietary treatment was used. In all cases in which the necessary concentration of beta-oxybutyric acid and the proper p_H could be obtained, the urinary infection cleared up very promptly. There were several instances in which the urine was sterile after forty-eight hours. In a number of these cases ammonium chloride and methenamine had been tried without success.

The twenty-four cases have been divided into three groups: (1) those in which the infection cleared up promptly as a result of the diet and in which the patient remained free from infection, (2) those in which the infection cleared up promptly but recurred, and (3) those in which the infection did not respond to the treatment, because the proper p_H and the necessary concentration of beta-oxybutyric acid could not be obtained in the urine. Twenty-one of the patients in this series were girls and only three were boys.

In the fifteen cases (table 1) in which there was no return of the infection, the cure was often extremely rapid. The number of days that the diet was administered does not indicate the length of time it took to render the urine sterile but the length of time it took to obtain a proper ketosis and the period that I felt it was necessary to keep the urine sterile in order to assure that all the organisms in the lining of the urinary passages would be killed. It is noted that, in most instances in which the necessary bactericidal conditions are achieved, the urine becomes sterile within twenty-four hours. As a rule, the ketogenic-antiketogenic ratio at which a proper ketosis is obtained lies between 3:1 and 4:1. In one instance in which sterilization of the urine of a 3 year old girl was complete after seven meals the ratio was only 2:1.

Fig. 2—Duplication of left ureter with megalo-ureter. a before operation b after operation

In the six cases in the second group (table 2), there was a marked tendency for the infection to relapse. Three of these patients lived near the clinic and the various recurrences of the urinary infection could be followed for a period of years. The urine of two other patients was sterile when they left the clinic but the infection recurred soon after they arrived home. Another patient returned in six weeks for a second dietary treatment and has not had a recurrence of the infection for about a year.

The third group was composed of three cases in which I was unable to obtain a proper ketosis or a low p_H in spite of the fact that the children took the diet without difficulty (table 3). In one of these cases the ketogenic-antiketogenic ratio was 5:1. In two cases the lowest p_H of the urine was 5.7 and 5.9, respectively.

TABLE 1—Treatment of Urinary Infection Without Obstruction Sterilization of Urine*

and at no time did the concentration of the beta-oxybutyric acid approach 0.5 per cent. These two patients were in the hospital and I was unable to account for the lack of adequate ketosis. A second trial of the diet unfortunately was not possible. In case 24 (table 3) the p_H ranged from 5.1 to 6.1. On

TABLE 2—Treatment of Urinary Infection Without Obstruction Recurrence of Infection and Repeated Sterilization of the Urine*

18	1	♀	15	5.0		Relapse with Streptococcus faecalis
19	9	♀	10	5.3	Greater than 0.5	Repeated cures and recurrences no relapse for more than a year
20	10	♀	7 0 4	5.3	Greater than 0.1	Repeated cures and recurrences no recurrence since 0/27/34
21	10	♀	4	5.3	Greater than 0.1	No result with ammonium chloride and methenamine repeated cures and recurrences

* All organisms Escherichia coli except when indicated differently

the fifth day there were only 100 organisms in 0.5 cc of urine. The p_H of the urine on this day was 5.6, it rose on the following days and reached 6.1 on the eighth day at which time there were innumerable bacteria in 0.5 cc of urine.

It is thus evident that the ketogenic diet should be reserved for those cases in which urinary infection is refractory to the ordinary modes of treatment. No

one should hope for beneficial results unless a weighed diet can be arranged for and the proper degree of ketosis and acidity can be achieved.

URINARY INFECTION WITH OBSTRUCTION

In cases in which urinary infection has been associated with anomalies of the urinary tract, it has been unusually difficult in the past to eliminate the infection. In the past fifteen years I have treated a large number of children with anomalies, by various means, and in only two cases have I been successful in rendering the urine sterile and having it remain so after the treatment has been discontinued. In the one case there was a relapse within a month, and in the other case there was a relapse within a year. The lack of therapeutic results in these cases has been so striking that, together with others, I have felt that, if a cure was not achieved after active treatment had been employed for from three to four weeks, the patient probably had an anomaly of the urinary tract, with urinary stasis.

It was a great surprise, therefore, that the ketogenic diet would successfully clear up urinary infections in the presence of even severe degrees of stasis. My first

TABLE 3—Treatment of Urinary Infection Without Obstruction Failure of Diet*

report on the subject emphasized the excellent results in cases in which there was stasis in the urinary tract, because it was this group, in particular in which my treatment had been almost always unsuccessful.

In a series of twenty-one cases of urinary infection there were a great variety of severe obstructive lesions of the urinary tract. A bactericidal urine cannot do more than kill the bacteria with which it comes in contact, so that the vesical ureteral or pelvic wall when seriously infected or an interstitial lesion of the kidney can be influenced only indirectly by the diet. The urinary tract finally may be rendered sterile if, by rendering the urine sterile further infection of the tissues is prevented and normal healing of the lesions is allowed to take place. As the urine can be rendered bactericidal by means of the diet, there is no reason why it should not sterilize a urinary tract that is the seat of stasis as well as one that is not.

I have divided the twenty-one cases into (1) a group of six cases in which the urinary tract has remained free from infection for a period of time after discontinuing the diet, (2) a group of five in which there has been a recurrence after a period of freedom from infection after discontinuing the diet and (3) a group of ten cases in which it was impossible to influence the infection at any time.

GROUP 1—As will be seen from table 4, the patients who are included in this group had normal renal function. In no case was the value for the urea more than

38 mg per hundred cubic centimeters of blood, and all these patients excreted a urine that had a low p_H and a high concentration of beta-oxybutyric acid. The obstruction in these cases was of such a nature that, even after the operative procedure, there still remained sufficient dilatation of the urinary tract to render it abnormal.

Two recent cases seem worthy of detailed description, because they show the severity of lesions that can be cleared up in cases in which operative procedures at the present time offer no solution, and the rapidity with which infection may clear up after relief of the main obstruction.

CASE 2 (table 4)—A girl, aged 8 years, had a bilateral hydronephrosis and megaloureters, without any obstruction in the ureter bladder or urethra. The condition probably was of neurogenic origin. (The excretory urogram is illustrated in figure 1.) The patient had nephrostomy tubes in both kidneys. There was an acute infection and mucopus was draining from the tubes. Two previous attempts with the diet ended in fail-

ure. These were followed by a protracted period of unsuccessful treatment with urinary antiseptics. A third attempt with the diet, after both nephrostomy tubes had been removed, was successful. This probably was as severe an infection as I have seen and one in which a final attempt was made with what appeared to be a hopeless case, with a surprising result (table 5). The urine has remained sterile for eighteen months.

CASE 3 (table 4)—A girl aged 9 years had a duplication of the ureter and pelvis of the left kidney and a marked dilatation of the lower third of each ureter. (The excretory urogram is shown in figure 2.) The ureter from the upper segment entered the bladder through a pin point meatus, that from the lower segment entered the bladder through a gaping meatus. Meatotomy was performed on the ureter, which was 3 cm. in diameter. One month after operation the diameter of this ureter was 1.7 cm. The ketogenic diet was started eight days after operation and the urine was sterile after twelve days (table 6).

GROUP 2—This group consists of five cases with equally severe obstructive lesions in which there was a complete sterilization of the urinary tract, but, after a varying interval of from a few days to as long as seven months there was a relapse (table 7). In one case there was a marked tendency for the infection to relapse until local treatment of the bladder and dilated ureteral stump was used. The urine has been sterile for seven months.

GROUP 3—This group includes the ten cases in which the ketogenic diet failed to sterilize the urine (table 8). This group of ten cases can be subdivided into a group of five cases in which stones were present and a group of five cases in which no stones were present. In the only case in which the amount of urea in the blood was

increased when the patient was admitted to the hospital, it dropped rapidly to normal after removal of putty-like material from the pelvis of a solitary kidney. In only one of the five cases in which stones were present was it possible to get the p_H of the urine below 5.5. It was possible in this case to lower the p_H to 5.2 and to increase the concentration of beta-oxybutyric acid to 1.4 per cent. This patient had a double urinary infection with *Streptococcus faecalis* and gram-negative bacilli when she was first seen at the clinic. Ureteral catheterization, while the diet was being employed, revealed that the urine from the kidney without stones was sterile and that a culture of the urine which was obtained from the calculous kidney was positive for *Streptococcus* but negative for *Escherichia coli*. Stones had been removed from both kidneys, but two small stones had formed later in the left kidney. In two of the other cases in which there were stones the p_H of the urine could not be brought below 6.1 and 8.3, respectively. Although in the latter case the concentration of beta-oxybutyric acid at one determination was 1.4 per cent, it was never more than 0.22 per cent in the former case.

TABLE 6—Clinical Data in Case 3 Table 4

In the group of five cases in which there were no stones, the concentration of beta-oxybutyric acid in the urine was always less than 0.5 per cent. In only two of these cases was the p_H of the urine 5.5 or less. This is the group in which one would not expect to obtain satisfactory results. It also is the group in which one must attempt to increase the output of beta-oxybutyric acid and attempt to lower the p_H of the urine. Whether this can be accomplished in cases in which renal func-

tion is impaired and the amount of urea in the blood is increased is a question. One patient who had a neuromuscular dysfunction of the bladder had been subjected to a presacral neurectomy. The residual urine had been reduced from 600 to 60 cc. This patient was fed beta-oxybutyric acid in capsules. The bacteria in 0.5 cc of urine were reduced to 100. Cook⁴ has shown that, in certain cases in which the p_H of the urine of an adult can be lowered, the feeding of beta-oxybutyric acid in capsules will increase its concentration in the urine to more than 0.5 per cent and will clear up an infection. In another case, a boy had a severe urinary infection with *Pseudomonas*, a recurring of abscesses of the liver, and cirrhosis. In this case neither the p_H of the urine nor the concentration of beta-oxybutyric acid could be brought within the bactericidal range. The administration of ammonium chloride failed to reduce the p_H of the urine, and the administration of beta-oxybutyric acid by mouth did not effect the output of this acid in the urine.

This group of cases represents rather well what can be expected of this form of dietary treatment of urinary infections. In cases in which it is possible to produce bactericidal conditions in the urine by feeding a patient the ketogenic diet either alone or with the addition of ammonium chloride and beta-oxybutyric acid, to decrease the p_H and to increase the concentration of beta-oxybutyric acid in the urine, it is possible

to clear up a considerable number of infections which are associated with urinary stasis. Stones and reduced renal function are almost absolute obstacles to successful therapy.

SUMMARY

The ketogenic diet is a useful method for treating urinary infections resistant to alkalinization, diuresis and urinary antiseptics. In cases in which urinary

anomalies are associated with stasis, a temporary and often a permanent cure of the infection can be achieved in those cases in which a p_H of less than 5.5 and a concentration of 0.5 per cent beta-oxybutyric acid can

be maintained in the urine for a period of time. Nephrolithiasis and impaired renal function are two serious handicaps to the success of this form of treatment.

ABSTRACT OF DISCUSSION

DR. EDWARD L. BAUER, Philadelphia. Dr. Helmholtz's presentation not only is a positive declaration of another therapeutic approach to a condition that is often most obstinate but also brings out most clearly the limitations of the treatment. He states that it is only the obstinate case in which the treatment should be tried and that the ketosis is of no value when there is obstruction to natural drainage in the urinary tract. This is particularly true when stones are present. It is important to appreciate these facts and the reasons that he has cited for recurrences and, may I add, the possibility of new infections, otherwise, resulting failure may invite an unjust adverse criticism. Emphasis should be placed on the importance of weighing out the diets and the necessity for closely watching the patient so that there will be no cheating and a consequent failure to obtain ketosis. Those of us who have tried these diets have found that it is sometimes impossible to make the child eat. Some will try and at the first sign of nausea will resist all further efforts to be fed. In a few others it just seems impossible to approach ketosis no matter how accurate the ratios may be. These handicaps should not stand in the way of utilizing this procedure in nonobstructive chronic infections of the urinary tract.

CONVALESCENT SCARLET FEVER SERUM

ITS PROPHYLACTIC AND THERAPEUTIC VALUE
A REVIEW OF 2875 CASES

ARCHIBALD L. HOYNE, M.D.

WILLIAM THALHIMER, M.D.
CHICAGO

Convalescent scarlet fever serum for both prophylactic and therapeutic purposes is an agent whose value has been well established for some years. However, its extensive use has been limited by the difficulties involved in obtaining and preparing an adequate supply. The Samuel Deutsch Serum Center has concentrated its efforts to make available a liberal quantity of pooled convalescent scarlet fever serum for the contagious disease hospitals and for private physicians in Chicago who may desire it.

Results obtained with this serum have been studied, followed and recorded. Information cards were sent to every physician who used serum in his private practice. In most instances these forms were fully answered and returned. At times the physician neglected to record all the data, but if the essential facts were set forth the card was filed for future analysis. Otherwise a letter was sent requesting the additional information. If this could not be obtained, the report was discarded. The data in respect to serum treated patients in the Municipal Contagious Disease Hospital of Chicago were secured from the hospital charts, which gave uniform and precise histories.

The present paper is an analysis of the information derived from these two sources during two and one-half years' experience. Not only were the general effects analyzed but a particular effort was made to determine whether any influence was exerted by convalescent serum therapy on complications and on mortality. These aspects of our investigation were given special attention because of the dissenting reports in the literature.

PROPHYLAXIS

Convalescent scarlet fever serum has been employed for many years in the protection of individuals exposed to scarlet fever. Its efficiency has been uniformly favorable.

Degkwitz's¹ report on passively immunizing 509 scarlet fever contacts with doses of from 5 to 6 cc of convalescent serum for children under 8 years of age, and 10 cc for those from 9 to 14 years, is really amazing. All but three escaped scarlet fever. Meader² injected 7.5 cc of convalescent scarlet fever serum in each of 450 contacts, of whom 29 per cent contracted the disease, as contrasted with 321 control contacts, unprotected, of whom 128 per cent developed the disease. Apparently 85 per cent were protected. These two reports would be of more value if the susceptibility of the contacts had been known. The Dicks³ in their report not only considered this factor but also determined the presence of infection. In their series of con-

tacts they made both skin tests and throat cultures. Those who were Dick positive but had cultures negative for hemolytic streptococci were actively immunized. On the other hand, the ones who had both positive skin tests and positive throat cultures for hemolytic streptococci were passively immunized with convalescent scarlet fever serum. Fifty per cent of the latter group already had sore throat and fever at the time convalescent serum was injected. In none, however, did scarlet fever develop. This was a most rigorous and critical test of the value of convalescent serum for passive immunization.

Gordon⁴ at the Herman Kiefer Hospital passively immunized student nurses who, when reporting for training, were found to be Dick positive. In a group of 112 such nurses who received 15 cc of human scarlet fever convalescent serum, 92 per cent were protected, eight who contracted scarlet fever had very mild attacks.

Because of these reports, 7.5 cc of serum was employed for prophylaxis at the beginning of this study, but within a year the dose was increased, so that 10 cc was used for children under 10 years of age and 20 cc for those over this age. The serum was given chiefly to intimate home contacts who had no history of having had scarlet fever.

TABLE 1—Scarlet Fever Prophylaxis in 862 Home Contacts Giving No History of Scarlet Fever

Age Years	Num- ber of Cases	No Scarlet Fever	Mild or Modified Scarlet Fever Incubation Period	Unmodified Scarlet Fever Incubation Period	Per Cent No Scarlet Fever

Nine patients developed scarlet fever from three to five weeks later.
Sixteen patients developed acute pharyngitis or tonsillitis.
Five patients developed cervical adenitis or otitis media.

Reports susceptible of analysis were received on 862 such prophylactic inoculations. Eighty per cent of the contacts were immunized within the first three days after exposure, about 10 per cent after three days, and in 10 per cent the duration of exposure was not recorded. The exact figures are shown in table 1. Scarlet fever developed in twenty-four contacts. In twelve the incubation period was not recorded, in seven it was markedly delayed, and in five the usual incubation period preceded the illness. Additional reports were made on nine other patients who escaped the disease following serum administration but contracted scarlet fever from three to five weeks later following a reexposure, without serum protection being repeated.

It is interesting to note that in sixteen patients acute pharyngitis or tonsillitis developed after exposure to scarlet fever following serum injection, and five had cervical adenitis or otitis media. However, there was no rash and the cases were not considered scarlet fever.

Serum was administered to children in general hospital wards when exposed to active cases of scarlet

pital, Detroit, June 1934.

fever developing in the wards. These contacts were Dick tested, and only Dick-positive patients received convalescent serum. Of eighty-three patients immunized, scarlet fever developed in four after a prolonged incubation period (table 2). In all four cases the disease was mild and atypical. The throat cultures were positive for hemolytic streptococci.

Among those in whom mild scarlet fever appeared, the majority had a definitely modified type of the disease. This form of scarlet fever was characterized by

a transient evanescent rash, by a rise of temperature of only one or two degrees, and by the absence of angina and toxemia. Without a history of susceptibility and exposure they might very easily have been overlooked. They were analogous to the sero-attenuated measles so frequently seen following exposure to measles and delayed administration of convalescent measles serum.

So-called mild or atypical scarlet fever is not of infrequent occurrence. Such types of the disease may be seen in other members of a family or group in which a case of severe scarlet fever exists. The atypical form is presumed to occur in those individuals who possess a partial natural immunity to the disease. Similarly, modified sero-attenuated scarlet fever is sometimes seen in individuals who have been artificially but incompletely immunized with convalescent serum or when the individual has been exposed to scarlet fever late in the period of passive immunization, i. e., after the tenth to the fourteenth day. The modified disease is of the same character as the "atypical" mild disease that develops in the presence of a partial natural immunity.

When immediate protection is secured by serum injection, passive immunity has been induced and this can be relied on to endure for only ten to fourteen days. Therefore, with prolonged exposure of susceptible individuals, repeated injections at ten-day intervals are advisable until the source of possible infection has been removed. Since there is no sensitization produced by human serum, repeated inoculations may be given without fear of serious reactions or development of unpleasant consequences.

THERAPY

The consensus⁵ in the literature is that the pooled convalescent scarlet fever serum has a beneficial influence on the early toxemia, angina, temperature and rash of scarlet fever, although different views are held as to the degree of such beneficial action. However, there is a pronounced divergence of opinion on the

value of convalescent serum in preventing or alleviating the complications associated with this disease, and necessarily on the mortality. Thus, Toomey⁶ believes that the effect of serum is antitoxic only and that one cannot expect any therapeutic effect in the complicated cases. Birkhaug,⁷ admitting a rapid diminution in the toxic manifestations, finds no influence on the septic complications. Ciuca, Craciunescu and Bahov,⁸ although considering convalescent serum an indispensable measure in toxic forms of scarlet fever, believe that it has no direct action on the angina or on the complications. Bode⁹ likewise could not ascertain any effect on complications. Opposing these conclusions, however, are others that a favorable influence is observed on complications by administration of convalescent serum. Kling and Widfeldt,¹⁰ although acknowledging a less noticeable effect on complications than on the mortality or severity of the illness, state nevertheless that improvement in complications was observed. Gordon, Bernbaum and Sheffield,⁵ in their analysis of 120 severely sick scarlet fever patients treated with convalescent serum, believed that complications were less frequent.

Bahov¹¹ in a study of 1,000 scarlet fever cases, stated that pooled convalescent serum is the ideal form of therapy and that, when given, it prevents streptococcal complications. Prinzing,¹² in a comparison of ninety-seven serum treated and 257 untreated cases found the results given in table 3. His conclusions were that the injection of serum reduced markedly the incidence of complications in those cases which he had analyzed.

Information for our study was obtained from 983 reports sent in by private physicians and from observations of 947 patients in the Municipal Contagious Disease Hospital.

Before the data are discussed, it is necessary to consider certain essential conditions. During the period (1932-1934) in which serum was employed, the clinical type of scarlet fever in the city of Chicago was at least of the same average severity as it had been for several years previously. Because the supply of convalescent

serum was limited, its use was restricted, as far as possible, to severely sick patients. Although early and prompt treatment was urged, this frequently was not done so that many patients did not receive serum for a week or more after the onset of their illness. Serum was never withheld from a patient even though he was moribund when first seen. Too often septic complica-

tions of a hopeless nature were present, but even in the face of a fatal termination serum was used

The hospital group and private group showed two important differences. Owing to delay in hospitalization of patients, only 42 per cent received treatment in the first three days of their illness whereas in the home group 79 per cent were treated during this period. Secondly, it was possible to maintain more rigid control of serum administration in the hospital, and consequently serum was employed only for critically sick patients. Such restriction could not be enforced for those patients treated in the home, therefore this group was made up of 33 per cent severe, 47 per cent moderately severe and 20 per cent mild cases. It must be kept in mind that any difference in the results obtained with scarlet fever therapy should definitely favor the home-treated patients.

Other factors that must be considered in analyzing these two groups are the dosage of serum and the route of administration. In the group treated at the contagious disease hospital the dose varied from 20 to 100 cc, the average dose being approximately 30 cc. In those treated at home the dose administered also varied from 20 to 100 cc, but more serum was used in the individual cases, so that the average dose was 40 cc. On the other hand, the route of administration in the home-treated group was almost invariably intramuscular, whereas in the hospital-treated cases a great many received the serum intravenously. This was particularly true during the last year (1934), when the favorable outcome obtained by this method of administration was much more impressive.

Efficiency of treatment can be analyzed from two different angles: first from the clinical impression of the effect of serum therapy on the general condition, toxemia, angina and rash; second from the statistical evidence of the effect of serum on temperature, complications and fatality.

The therapeutic effects of the serum as observed by various physicians in the treatment of private patients were good in 81 per cent, fair in 8 per cent, and questionable or of no benefit in the others (11 per cent). In the hospital, good results were recorded in 75 per cent of the cases, fair results in 11 per cent, and questionable or no effect in the remaining 14 per cent. The most notable and immediate influence of the serum was on toxemia which in most cases was markedly diminished. In the majority of cases there was also a prompt improvement in the anginal symptoms. The effect on the eruption was less evident but, as has been previously reported, it was most apparent when the serum was given within the first twenty-four hours of the disease. Serum administered at this time very often produced a rapid and complete disappearance of the rash. The desquamation in the latter cases was usually of a very fine branny nature or absent entirely. When serum was given later in the course of the illness after the rash had been present for two or more days, the general blanching effect was less pronounced.

No statistical analysis could be made regarding the effects of serum on temperature in the home-treated cases but reports from physicians were uniform in stating a marked temperature drop in from twelve to forty-eight hours following injection of the serum. The occasional exception was observed only in those patients who were suffering from severe complications at the time serum was administered. The hospital records provide more precise information concerning temperature. A study of the charts of 947 hospital

patients disclosed an average drop in temperature at the end of twelve hours of 1.7 degrees, at the end of twenty-four hours of 2 degrees, and at the end of forty-eight hours of 2.6 degrees. In many instances there were dramatic reductions of 4 and 5 degrees within a few hours, but patients suffering from septic complications seldom responded in such an amazing manner.

The accompanying chart summarizes the reduction in temperature according to the day of illness on which serum was administered and brings out the interesting fact that those patients treated in the first three days of their illness had the greatest average reduction in temperature. The later the serum was administered the less pronounced was its effect. On and after the fifth day of illness the average drop in temperature at the end of forty-eight hours was not as great as at the end of twelve hours when the serum was given within the first three days.

Because the serum was prescribed as a therapeutic agent and not in an experimental fashion not only was it given to every critically sick patient admitted to the hospital or reported to the Serum Center but it was not denied to patients late in the course of the disease who were suffering from some apparently fatal complication. Owing to this policy, a similar control group was not secured.

In order to arrive at some decision as to the value of convalescent serum therapy in preventing or alleviating complications, the results recorded in the serum-treated groups are compared with the other admissions to the Municipal Contagious Disease Hospital during the same period. The latter group was made up of 6,282 patients who were but mildly or moderately ill when hospitalized.

Thus there are three different groups for consideration. The first and most severe group is made up of the hospital-treated patients, the second group in order of severity is the home-treated group, and the third, or least severe group, comprises those patients only mildly or moderately sick on admission to the hospital and not treated with serum (table 4).

Owing to the fact that about 53 per cent of the first group had complications on admission these complications were recorded under the caption *Before Serum*, since they were present before serum was administered. Because of this, the chances for the development of further complications were considered to be materially increased.

This has been the general experience with other types of therapy, but it was found that such progression did not usually take place after administration of convalescent scarlet fever serum. On comparing the incidence of complications in group 1 with those of group 3 it is seen that with two exceptions complications in the milder group (3) not given convalescent serum were more numerous than in the group (1) severely ill but treated with convalescent serum. Only

mastoiditis, with 0.7 per cent, and "other complications," which includes the less frequent and more serious conditions such as pneumonia and streptococcal meningitis, with 0.9 per cent, were more common in group 1. Particular attention must be called to the infrequent occurrence of hemorrhagic nephritis in group 1, 0.6 per cent as compared with 3.6 per cent in group 3.

It is extremely difficult to draw any comparison between groups 1 and 3 on account of the frequency of complications in group 1 at the time of admission to the hospital. More accurate evaluation of the effect of convalescent serum might be made if the two groups were more nearly alike. Because the preexistence of complications provides such a disturbing factor, the patients in group 1 free from complications at the time of serum administration were placed in a separate subgroup, designated After Serum in the table. Of the

fewer than in the other two groups. The number and percentage of the complication hemorrhagic nephritis occurs in group 2 in only 0.2 per cent of the patients as compared with 0.6 per cent in the severely ill patients in group 1, and as against 3.6 per cent in group 3, consisting of the moderately and mildly ill patients who did not receive convalescent serum.

Analysis of the mortality in the serum-treated hospital patients presents a complex problem. The difficulty of analysis is caused by the policy of treating all critically ill patients. As a result, it was to be expected that the mortality would be very high. Many patients succumbing to scarlet fever or its complications were rushed to the hospital at the last moment in a moribund state and yet were given serum. Thus, most of the patients dying in the hospital received serum. Seventy per cent of these deaths occurred in patients who were not treated until after the fifth day of illness, and there

* AS indicates complications developing after serum administration. BS complications present before serum administration. The percentage of complications in the AS group was calculated after the number of patients in the BS group was deducted from the total number of patients.

947 serum patients treated in the hospital, 446 had no complications at the time they were admitted. Of these 446 patients, no complications developed in 79 per cent. The complications that did appear in this group were decidedly fewer than in group 3, in which serum therapy was not given (table 5). The greatest significance must be attached to the figures shown in table 5, for the patients in group 1 were clinically classed as severely or critically sick, a group in which a much higher incidence of complications may be expected than in the milder types of scarlet fever.

Group 2, the home-treated patients, contains severe, moderate and mild cases and occupies a midway position between groups 1 and 3. In the reports submitted by physicians, there were many instances in which it was not clear whether the complications recorded were present at the time serum was given or developed after serum administration. In all instances in which there was doubt, such complications were recorded for this report as having developed after the administration of serum, making a more severe test of the value of serum. In this group, all complications are much

was a steady increase in the fatality rate with the prolonged duration of illness before serum was given. To appreciate better the type of patient that was treated, the clinical condition at the time of serum administration and the course subsequent to serum injection, the deaths of hospital patients treated in the first five days of their illness are recorded in table 6. The remaining fatalities occurred in patients who received serum later than the fifth day of their illness. This group was made up entirely of individuals even more critically ill and with one or more severe complications.

On the other hand, it is interesting to examine the mortality figures in the home-treated group, a group that was treated mostly in the first few days of the disease. Here it is seen that the total mortality was only 1.7 per cent, although the majority of patients who died received serum after the third day of illness. Table 7 summarizes all the deaths in the home-treated patients. A study of these tables will show that in nearly all instances the patients who died were either moribund or were suffering from some complication that made the prognosis very grave before serum

administration The figure on mortality that is highly significant is the fatality rate of the private patients treated in the first three days This rate in 773 patients is but 0.5 per cent, approximately one-third the fatality rate of this disease throughout the city at the same time

In our experience, no sensitization to convalescent serum is developed nor are any unfavorable reactions produced An occasional urticaria-like eruption has been witnessed, but no definite picture of a true serum sickness has occurred Despite extensive administration of large doses of serum by the intravenous route, no shock or unpleasant reaction was produced among the cases reviewed in this paper No blood typing or matching is required in the administration of human convalescent serum

The following regulations should be adhered to in this form of therapy

1 The serum should be given early in the course of the disease, preferably within the first three days of illness

2 Adequate dosage is of the utmost importance. Although a minimum dose of 20 cc. may be sufficient, from 40 to 100 cc. may be required Age of the patient, severity of the illness, duration of the disease and experience with this form of treatment will determine the proper dosage Usually a single injection of the proper amount of serum is sufficient in the uncomplicated case At times, when severe complications are present, repeated injections of serum at intervals of twelve or twenty-four hours may be necessary

3 Although intramuscular therapy is satisfactory, the intravenous route is preferable, because of the immediate distribution of serum For intravenous use the following precautions should be observed (a) The serum should be warmed to body temperature in a warm water bath and injected slowly, (b) the syringes used for injection must be chemically clean, having been sterilized in distilled water

COMMENT

On the basis of the evidence that human convalescent scarlet fever serum is valuable for passive immunization, the following measures may be applied in the hospital or in the home

In a contagious disease hospital, where patients with a variety of infectious diseases are admitted, occasionally and unavoidably a patient who is not suffering from scarlet fever may be exposed to this infection Under such circumstances an intramuscular injection of 10 cc of convalescent scarlet fever serum is usually sufficient for immediate protection The immunity, however, lasts only from ten days to two weeks This must be kept in mind, and subsequent injections of convalescent serum should be given at ten-day intervals if exposure to scarlet fever continues

In the home the protection by passive immunization with convalescent scarlet fever serum is equally valuable This is particularly true when there are a number of children in the family and the ill child remains at home If all contacts could be immediately immunized, the number of multiple cases in a family would be materially reduced For example, among scarlet fever patients admitted to the Municipal Contagious Disease Hospital of Chicago in 1932, there were in the families of these patients 488 multiple cases In 1933 there were 761 multiple cases, and in the first six months of 1934 there were 522 multiple cases These cases occurred in 210, 311 and 209 families respectively for the periods stated These totals mean that there were 730 families in which scarlet fever was transmitted from the primary cases to contacts in the home on an average of 1.4 times, or a total

of 1041 cases that might have been prevented by prompt use of convalescent serum when the first case in the family developed

In the presence of a severe epidemic, exposed susceptible children should be passively immunized at intervals of every ten days, provided an adequate supply of serum is available Thus the use of convalescent serum might be applied to check an unusual outbreak of scarlet fever

In 1916 one of us (Hoyne) recommended the adoption of convalescent scarlet fever serum for the treatment of scarlet fever at the Municipal Contagious Disease Hospital of Chicago Although used in small quantities in isolated cases during the ensuing years it was only when the facilities of the Serum Center made available a substantial supply of serum that its extensive use became possible

Our results confirm the numerous reports of the beneficial therapeutic action of convalescent serum Particularly when administered in the first three days, it effects a marked diminution of temperature, allevia-

TABLE 5—Incidence of Complications in Hospital Patients Critically Ill but Free from Complications at the Time of Serum Administration

tion of throat symptoms, toxicity and prostration, and may cause a fading of the eruption The evidence we have compiled points strongly to a marked reduction in the incidence of complications as well as lowering of the mortality rate.

There is no statistical method of evaluating the effect of serum on existing complications Close observation of several hundred complicated cases, in which the patients were desperately ill on admission and were treated with serum, has convinced us that the majority of these patients have been definitely benefited by such treatment Our experience with this disease enables us to judge these cases fairly accurately Many patients with a septic process that we felt would advance have shown such definite improvement, with cessation of the progress of the disease, that we are forced to conclude that the serum played an active part in overcoming infection When the complicated cases are admitted in the late stages of the illness, we have supplemented convalescent serum with intramuscular injections of whole blood or with transfusions from individuals recently recovered from scarlet fever, with increasingly better results

With the limited knowledge of this disease, the mode of action of the serum in reducing complications and mortality is, at the present time, problematic It is possible that the beneficial effect is produced in an indirect manner by overcoming the toxemia and thereby

TABLE 6—Analysis of Those Deaths (Thirty-Eight) in the Hospital Group (737) Treated Within Five Days of Illness with Convalescent Serum

Age	Sex	Day of Illness Serum Administered	Number Cc	Condition on Serum Administration	Course	Time of Death After Serum Was Administered
5	♂	4	20	Moribund	No change	4 days

permitting the depressed general body defenses to act against those factors of the disease which are associated with the complications. On the other hand, convalescent serum may contain other substances indeterminate by present laboratory procedure, which act directly in preventing or alleviating complications.

Not only are scarlet fever complications a matter of importance as a factor in mortality or in late disability in the life of the patient but they also have a direct bearing on the cost of caring for the patient. In many instances, too, when scarlet fever patients remain in hospitals for prolonged periods, they reduce the number of available beds for acute cases that are in urgent need of hospital care. Therefore, any remedy that reduces the time of hospitalization promotes economy on a per capita basis and increases capacity through allowing hospital treatment of a greater number of patients within a given time.

It is generally acknowledged that scarlet fever morbidity and mortality fluctuate from time to time, and changes in virulence may be noted. One of us has been in a position to observe carefully the trend of this disease over many years. As has been stated, we feel that during the last three years (1932 to 1934 inclusive) the clinical disease has been at least as severe as during the preceding three-year period (1929 to 1931 inclusive). A comparison of the fatality rates of these two three-year periods may therefore be of interest, for in the last three years convalescent serum was used extensively both in the hospital and throughout Chicago.

The city records for 1929-1931 reveal 25,743 cases with 547 deaths, a case fatality rate of 2.13 per cent. The records for 1932-1934 show 26,611 cases with 419 deaths, a case fatality rate of 1.5 per cent. Similarly, the records of the Municipal Contagious Disease Hospital show for the years 1929-1931 without convalescent serum treatment 6,353 cases with 156 deaths, a case fatality rate of 2.46 per cent, as contrasted with the convalescent serum treatment years of 1932-1934 when there were 8,457 cases with 157 deaths, or a case fatality rate of 1.86 per cent. It is seen that the mortality throughout the city was lessened by 0.63 per cent and in the hospital by 0.60 per cent, an actual decrease of 29.6 and 24.4 per cent respectively. The explanation of the considerable reduction in the mortality rate may be attributed to the fact that, although convalescent serum was administered to only from 7 to 8 per cent of the total number of patients in the city, the group thus treated was made up chiefly of the severely sick or critically ill individuals. It is essentially this type of the disease that causes the greatest number of fatalities. Since the home-treated group showed a mortality rate of only 0.5 per cent in those patients treated in the first seventy-two hours of illness, a further reduction in fatality may be expected with more widespread, proper and early use of convalescent serum.

SUMMARY

1 Of 862 home contacts who gave no history of scarlet fever and were passively immunized with convalescent scarlet fever serum, scarlet fever did not develop in 97.2 per cent.

2 Of eighty-three Dick-positive hospital contacts immunized with convalescent scarlet fever serum, scarlet fever did not develop in 95 per cent.

3 In immunized contacts in whom scarlet fever developed, it was usually in a modified form, believed to have been produced by partial immunization and resultant sero-attenuation.

4 Convalescent scarlet fever serum in adequate therapeutic doses administered early may abort the disease and usually causes recession of fever, diminution of toxemia and angina, and fading of the rash and appreciably shortens the period of illness.

5 Convalescent scarlet fever serum, directly or indirectly, either prevented the development of complications or reduced the frequency of their occurrence.

6 The influence of serum on late and complicated cases was less marked but frequently seemed beneficial.

7 By reducing the severity of the disease and the incidence of complications, the mortality rate was definitely diminished.

8 No unfavorable reactions, serum sickness, sensitization or anaphylactic shock were encountered with the use of human convalescent scarlet fever serum.

BUFFERED LACTIC ACID EVAPORATED MILK IN INFANT FEEDING

FRANCIS SCOTT SMYTH, MD

AND

SAMUEL HURWITZ, MD

SAN FRANCISCO

Since the introduction of chemically acidified milk by Marriott,¹ numerous suggestions and modifications have been made regarding its use, but evaporated milk acidified with lactic acid has stood the test of repeated trials. There is still some skepticism, however, regarding the role of the acid. Marriott considered acid milk valuable because of further alteration of the milk curd and improved gastric digestion when the buffer salts of the milk are neutralized by acidification. Brennemann² reported his gradual adoption of Marriott's formula for acid milk after a clinical trial in the Children's Memorial Hospital in Chicago and his conclusion was "The result was all that has been claimed and all that could be hoped for, and again such as I had never seen before with any other food." As to the theoretical role of the acid, he believed that the effectiveness of the formula was due to the finer curd and not to the buffer, which might be increased or reduced without changing the value of the formula if the finer curd was obtained.

Schloss³ concurred with Brennemann's statement though he stressed the benefit of the altered curd from an allergic point of view. It has also been shown⁴ that acidified milk increases gastric motility, which in turn improves all gastric functions, including gastric secretion. There is also an increased absorption of fats, proteins and mineral matter with this type of feeding.⁵

At the St. Louis Children's Hospital Clinic it was recently shown⁶ that, when gastric acidity is lowered the acid formula will also prevent the growth of organisms in the upper portion of the intestinal tract. The relationship of infection of the middle ear to *B. coli* was demonstrated by obtaining cultures of this

From the Department of Pediatrics, University of California Medical School.

This study was made possible in part by a grant from the Evaporated Milk Association, Chicago.

organism from the gastric contents. The seeding of this organism in the upper portion of the respiratory tract is due to vomiting. A buffered acid mixture was devised to counteract the growth of *B. coli*, and it aided in maintaining a more normal gastric p_H and prevented the colon bacillus from entering the gastric zone.

Arnold's⁷ experimental work at the University of Illinois College of Medicine substantiated the clinical observations of the St. Louis group of investigators. He showed a definite mechanism by which the upper portion of the intestinal tract is kept free from the flora of the lower portion, which is largely a matter of acidity in the upper portion. It was found that this protection failed when counteracted by alkalis, and the colon bacillus could then grow in the stomach. There was sufficient permeability to allow these organisms to migrate through the intestinal wall, and cultures were obtained from the thoracic duct. It would seem that in conditions associated with a reduction of the gastric p_H benefit would be derived from acid feedings buffered to maintain a better acidity than is contained in the usual lactic acid formula. An interesting corollary was provided in the study of autonomic balance in various body functions by Petersen⁸ and his co-workers and by

and gavage was necessary. The stools became loose and watery and the infant appeared to be toxic. Gastric analysis showed a lowered acidity and a massive growth of *B. coli* on culture. Buffered acid milk was substituted for breast milk and buffered acid water was given between feedings. The stools decreased from nine to four daily on the third day and did not again increase in number. Regurgitation ceased four days after the buffered acid feedings were started. The subsequent course was satisfactory and the infant was discharged forty-three days after birth, weighing 3,500 Gm.

Encouraged by individual results, we initiated a routine procedure that would enable us to study any untoward symptoms resulting from the use of buffered milk for normal new-born, delicate and premature infants. As an analysis of the results of such a program would be difficult without control groups, we made a number of studies with different formulas and used them for purposes of comparison.

The growing tendency to prevent an initial loss of weight by giving weak alkali solutions was a further reason for this report. We are now making a comparative study, which will be reported later, of the effects of buffered acid sugar water and the alkaline sugar mixture that has been recommended by Eder and Bake-

Müller⁹ with his theory of splanchnoperipheral equilibrium. They showed that an increased functional activity of the skin is accompanied by peripheral leukocytosis, an inhibition of function and leukopenia of the splanchnic organs.

Clinically, a high external temperature or fever in the case of an extremely weak or premature infant is accompanied by a lowered gastric acidity and, hence, an acid formula is indicated in such cases.

We have used the buffered acid milk since January 1931, though at first only in selected cases. A protocol of one case follows.

REPORT OF CASE

Baby R., a first-born child, with right occipitoposterior presentation, weighed 2,000 Gm at birth. External heat, which was applied because of the subnormal temperature, caused a cutaneous burn. The infant's temperature rose to 40°C (104°F). Breast milk, reinforced with Dryco was used and fluids were administered parenterally. The feedings were poorly taken

well¹⁰ and others. Whether the use of weak alkali solutions promotes unexpected phenomena of a serious nature remains to be seen. It may be that early alkali feedings stimulate the production of gastric acidity in the average normal infant, but before that occurs the earlier danger of hypo-acidity may eventuate.

METHOD

The buffered lactic acid formula used in this study was prepared as follows:

A buffer solution consisting of lactic acid 15 cc., 10 per cent solution of sodium hydroxide 20 cc., and water to total 500 cc. was made up as a stock solution. Equal parts of this mixture and of evaporated milk were used and 10 per cent added Karo was supplied.

This formula has a caloric value of 110 calories per hundred cubic centimeters. The p_H value is 4.2, which corresponds approximately to the hydrogen ion concentration of gastric juice at the time of optimum digestion in an infant who is being fed cow's milk.¹¹ In the clinic this special formula was used for infants when nursing was considered impossible because of prematurity or complications such as sepsis or cesarean section, when the mother did not wish to nurse her

infant, and also to complement the breast feeding of infants who weighed less than 3,000 Gm. Most of these infants were from families in the lower social stratum, some being illegitimate.

The formula was started eight hours after birth except in the case of premature infants, for whom about six hours elapsed between the time of delivery and the first feeding.

RESULTS

There was no difficulty in initiating the buffered lactic acid formula, and it was the general impression that this formula was easier to start and increase than the straight lactic acid mixture. The infants fed on buffered lactic acid milk appeared to be satisfied and

The four hour schedule was used except for premature infants, who were usually fed every two or three hours by gavage or with a Breck feeder or medicine dropper. All full term infants fed on this formula were offered 110 calories per kilogram of body weight daily. Breast fed infants were offered 10 per cent Karo water after nursing so that the caloric intake was normal but never in excess of 2 ounces (60 cc.) at a feeding. Water was given freely to all infants between feedings.

showed excellent tissue turgor. The stools were somewhat lighter in color than those of breast fed babies, but the average number was about the same in the two groups. Although regurgitations appeared to be more frequent in this group, this is not a true representation of conditions. Early in the study a more concentrated formula was employed, but when the strength was

reduced, as previously outlined, excessive regurgitation was adequately controlled. There was no gastro-intestinal disturbance severe enough to require discontinuance of the use of the buffered mixture and in some cases of diarrhea improvement was noted when the original formula was changed to buffered lactic acid evaporated milk.

Table 1 shows the results obtained with various formulas employed for full term infants during the period of this study, beginning Jan. 1, 1931. It is obvious that the initial loss of weight was less prolonged in the group who were fed the buffered milk (2.2 days) and averaged only 4.5 per cent of the birth weight. Both these figures surpassed similar ones for infants who were fed other types of artificial food. The results were better when buffered lactic acid evaporated milk was used to complement breast feeding both as regards the initial loss of weight and its duration. We believe that these figures are truly comparative since the average birth weight, which was slightly less in the buffered lactic acid group, was balanced by the greater incidence of first born infants in that group. The results in all our various series of studies are better than those reported previously by older authors. Fleischmann¹² reviewed the results of a number of studies on feedings and found that the total loss of body weight averaged 6.6 per cent of the birth weight (assuming the latter to be 3,300 Gm). In a series of 300 breast fed infants studied by Ramsey and Alley¹³ the average initial loss of weight was 240 Gm and the average duration of loss was three days. Bergmann¹⁴ reported an average loss of 7.8 per cent of the initial weight in a group of 1,000 infants. It may be assumed from these statistics that buffered lactic acid milk has a definite influence in reducing the initial loss of weight and its duration.

Approximately 72 per cent of the infants fed the buffered lactic acid formula had regained their birth weight by the tenth day, as compared to 57 per cent of those fed on other artificial foods and 51 per cent of those who were breast fed. Schulz,¹⁵ in a study of 600 infants, showed that 48 per cent had regained their original weight in ten days. Twenty-five per cent of the infants in Ramsey and Alley's series had regained their birth weight before being taken from the hospital on the tenth day. In a series of reports of 1,000 breast fed infants, Bergmann found that only 11.4 per cent had reached birth weight by the tenth day and 21.17 per cent by the end of the second week. The smaller number of infants discharged while below birth weight (6.7 per cent) is as striking as the higher percentage of recoveries of birth weight in the first ten days for the infants fed on buffered lactic acid milk. The period of hospitalization was approximately identical for all groups tabulated. The buffered lactic acid evaporated milk formula promoted a more rapid recovery of birth weight than any of the other types of infant feeding.

The average gain in weight of the children fed on the buffered lactic acid evaporated milk for the first ten days of life was 110.5 Gm, which surpassed that of any

other group. In this period the infants fed on buffered lactic acid milk showed approximately seven times as great an increase in weight as the other artificially fed infants. This increase in weight was reflected in the excellent tissue turgor and muscle tone of these infants. Furthermore, the morbidity in the group was almost as low as that recorded for breast fed infants. Our figures support Grulee's¹⁶ contention that the morbidity incidence in breast fed infants is less than in those who are artificially fed. However, if artificial feeding must be used, buffered lactic acid milk seems to be ideally suited for the purpose.

The buffered lactic acid formula is well borne by premature infants as is shown in tables 2 and 3. This group was composed of twenty-two infants, 45 per cent of whom were boys, approximately the same number being first born. In the other group (table 2) of twenty-nine infants, 24 per cent were boys and 69 per cent were first born. The average birth weight in the latter group was 1,922 Gm, slightly lower than that of the group on the buffered formula (2,209 Gm). The initial loss of weight in those fed on buffered lactic acid milk was 4.2 per cent and continued over a period of two and three-tenths days. In the miscellaneous group the average initial loss was 5.1 per cent of the birth weight and the average duration of the loss was two and eight-tenths days. The average daily gain for those on the buffered formula was 26.1 Gm, for the miscellaneous group, 24.6 Gm. These figures compare favorably with any we have seen reported in the literature for this age period. They are slightly higher than those of Hill,¹⁷ who in a series of eighty-two premature infants on a formula of three parts of breast milk and one part of evaporated milk showed an average gain in weight of 0.766 ± 0.11 ounce (22 ± 3 Gm) daily. Gleich¹⁸ found an average weekly gain of 148.5 Gm (daily average 21.2 Gm) in a series of twenty premature infants fed on lactic acid milk. He reported that there were no gastro-intestinal disturbances, which is in accord with our results with the buffered lactic acid formula. The morbidity is considerably less in the group fed on buffered lactic acid than in the comparable miscellaneous one (18.2 and 24.2 per cent, respectively) also, in spite of a greater number of boys in the buffered group, there was no increased incidence of icterus neonatorum.

CONCLUSION

It has been stated¹⁹ that acidified milks should not be given to infants less than 6 weeks of age, as they are not well tolerated. This contention has been challenged, however, by many and our study leads us to conclude that not only is buffered lactic acid milk exceedingly well tolerated but also, from a clinical standpoint, infants fed on this formula show (1) less initial loss of weight and more rapid recovery of birth weight, (2) less icterus neonatorum and (3) a more substantial gain over the birth weight at the end of the hospital period. Premature and congenitally debilitated infants are particularly benefited by such a buffered lactic acid evaporated milk formula.

Clinical Notes, Suggestions and New Instruments

DINITROPHENOL CATARACT

DAVID G. COGAN, M.D., AND FRANCES C. COGAN, M.D. Boston

We present two cases of acutely developing cataracts in relatively young people, which came on following the administration of dinitrophenol and which we consider to be referable to the same etiology. One of these cases we have had the opportunity of studying at the Massachusetts Eye and Ear Infirmary, and the other has been brought to our attention through the courtesy of the Johns Hopkins Hospital staff.

CASE 1—M. L., a 38 year old Scotsman, entered the Massachusetts Eye and Ear Infirmary in May 1935, complaining of a haze before his eyes. The family history was irrelevant. Both parents had lived to old age and neither had had significant ocular trouble to the time of their deaths. Several siblings were living and well and without ocular complaints.

The patient had been a proofreader for some years and was not exposed to industrial hazards. He had always been well but was somewhat overweight.

In February 1934 he began taking dinitrophenol for weight reduction, at first in a dosage of 3 grains (0.2 Gm.) daily but rapidly increased to 8 grains (0.5 Gm.) daily. While taking the drug the patient experienced periods of excessive weakness lasting from one to two hours which would come on at the time of maximum perspiration. In addition there was a throat infection which seemed to accompany the use of the drug. No blood study was made at this time. After taking the drug for approximately four months and losing from 2 to 3 pounds weekly the patient began to notice paresthesias of his extremities of momentary duration. Later the paresthesias became more lasting and extensive, resulting in a continuous numbness of his ankles and toes. Eventually he experienced intense shooting pains in the tips of the toes and the joints, later he had similar pains in his hands without at any time swelling or other evidence of inflammation. His extremities felt so hot that he could not tolerate bed covers, even at freezing temperatures. Following the attacks of pain his extremities were decidedly hyperesthetic and weak so that he was forced to use crutches. The patient discontinued use of the drug but the symptoms lasted approximately six weeks. On thorough medical examination at this time no significant changes were noted other than the neuritis with loss of light touch of the lower extremities for which the drug was considered responsible. About this time or shortly before, the patient began to have some visual difficulty. Unfortunately no adequate examination of the eyes was made at this time. In January he had his glasses changed but still could not focus. His vision became progressively blurred during the next few weeks, hence he came to the Massachusetts Eye and Ear Infirmary.

Physical examination revealed nothing of note other than moderate obesity. There was no evidence of glandular dysfunction or of premature senility.

The ocular examination gave practically identical results in the two eyes and may be described therefore as one. The vision was 20/20 seen through a haze.

Refraction OD—0.75 — 0.25 × 180, OS—1.00 — 0.25 × 180. Accommodation 2 diopters.

The corneas were clear. There were no keratic precipitates but there was a faint outstanding beam in each aqueous without any formed particles. The irises were normal. There were many fine stippled and polychromatic opacities in the anterior lens subepithelial cortex forming a superficial shell. There were no definite crystals. Many vacuoles under the epithelium protruded onto the surface thereby roughening it. There was a striking accentuation of these opacities in a central region about 5 mm. in diameter, i.e., in a semidilated pupillary area. The rest of the anterior cortex was clear except for a few round punctate opacities probably coronary in character. The nucleus was clear. The posterior cortex where changes were the most marked showed a shell-shaped opacity in the central region corresponding to the opacity of the anterior

cortex. This formed a golden yellow, striped opacity of the posterior cortex outlining the sutures. It was poorly demarcated from the rest of the superjacent cortex, but fairly sharply demarcated from the periphery of the posterior cortex. The vitreous, which could be seen through the periphery of the lens, appeared normal. The fundi were normal. The disks were of good color. The vessels were normal. There was no exudate, hemorrhage or other lesion.

The patient was seen again two weeks after the previous visit. At this time vision was reduced to the counting of fingers at 2 feet, with proportionate clouding of the lenses. The subepithelial fine opacities, with many vacuoles were present as before but seemed insignificant compared with the gross flocculent precipitates throughout the entire anterior cortex. These resembled the opacities of a rapidly developing senile cortical cataract. The opaque posterior cortex could be appreciated only by the contrawise movement of the light reflex. These opacities now extended to the periphery of the lens. No red reflex could be obtained from the fundus. Subsequently the patient had simple cataract extraction in each eye with uneventful convalescence. The fundi, which are again visible, still show no lesion.

Serologic examinations gave negative results. Chemical examination of the calcium, sugar, nonprotein nitrogen and cholesterol content of the blood gave negative results. Red blood corpuscles numbered 5,360,000; white blood corpuscles, 8,850, with a differential count of polymorphonuclears 59 per cent, lymphocytes 31 per cent, mononuclears 8 per cent, eosinophils 15 per cent and basophils 0.5 per cent.

CASE 2—R. A., a white woman aged 25 married, was admitted to the Johns Hopkins Hospital, April 28, 1935, with the complaint of obesity, nervousness, and rapidly failing vision.

The past history and the family history were essentially negative.

Two and one-half years before entry, the patient had a rapid gain in weight following pregnancy. One year before entry, she became extremely nervous. Four months before entry because of another rapid gain in weight, she was given thyroid and dinitrophenol, the latter in 1½ grain (0.1 Gm.) capsules three times a day. She continued this medication for approximately one month. (There was some question of her having taken dinitrophenol for a short period one year previously.) Three or four weeks before entry she noticed a beginning loss of vision in her left eye.

The patient was obese and did not appear to be ill. Nothing of any significance was found except for her eyes and the obesity. There was no evidence of any glandular dyscrasia. The report of the eye consultation was as follows: "External examination lids negative; conjunctivae and corneas clear. Tension external ocular muscles and pupils normal. Ophthalmoscopic: Right eye, some clouding along the lens sutures. Fundus distinctly seen and apparently normal. Left eye, complete clouding of lens. Fundus cannot be seen. Vision R E 20/30, L E light perception. Fields normal. Impression incipient cataract of right eye, mature cataract of left eye."

The Wassermann and flocculation tests were negative. Blood calcium was 9.69 mg. per hundred cubic centimeters, sugar, 82; nonprotein nitrogen, 25; van den Bergh test, negative; red blood corpuscles, 4,900,000; white blood corpuscles, 8,160; differential, normal. The urine was normal. The basal metabolic rate was plus 48 (fairly satisfactory), plus 8 (satisfactory), plus 22 (satisfactory).

COMMENT

These two instances of rapidly developing cataract of a characteristic morphology occurred in relatively young persons in whom thorough study failed to reveal any etiologic factor other than dinitrophenol. The type of cataract which the first patient showed was per se suggestive of some systemic intoxication. The initial opacities occupied predominantly the posterior cortex but were not clearly demarcated from the surrounding areas. They progressed with extreme rapidity and formed a characteristic polychromatic luster in the zone of specular reflection. This is the type of cataract which Vogt¹ calls *cataracta complicata* and which is characteristic

¹ Vogt A. *Spaltlampe*. Microscopie 2: 536.

of exogenous injury.² We did not have the opportunity to make slit lamp studies in the second case, but the described accentuation of suture lines, together with the apparent rapidity of development, points to the same type of cataract. In view of the morphology of the lens changes in our case and the known effects of dinitrophenol on tissue metabolism, it seems likely that the cataracts are the result of damage to the lens epithelium rather than to primary precipitation of the lens constituents. This is why the toxic effects, as in our cases, occur not as immediate reactions but after prolonged use of the drug and may occur after the drug has been discontinued. It is significant that we have immersed immature cataractous lenses (removed intracapsularly) in a 2 per cent solution of dinitrophenol without the development of further opacities, as we might expect were it a precipitation of the lens substance.

In the two cases reported here only therapeutic doses had been taken, and cataracts developed subsequently. Toxic neuritis also developed in case 1, but no other evidence of intoxication appeared in case 2.

Massachusetts Eye and Ear Infirmary

CATARACT FOLLOWING THE USE OF DINITROPHENOL

N. K. LAZAR, M.D., CHICAGO

Horner, Jones and Boardman¹ reported several cases of cataract following the use of sodium dinitrophenol as an adjunct in the treatment of obesity. Their description of the lens changes are somewhat similar to those found in tetany and myasthenia gravis. Recently a case was observed at the eye dispensary of the Cook County Hospital which is herein reported. It will be observed that not only the lens but also the refractive error has undergone changes, which are not unlike those reported by Horner, Jones and Boardman. Also, apparently when other lens changes have occurred prior to the taking of the drug, there is a possibility that this may hasten the further development of cataractous changes in the lens. Work on lower animals with this drug so far as the eye is concerned is indicated, not only for its scientific value but because of the widespread use of the drug.

REPORT OF CASE

Mrs. K., aged 44, white, was seen July 12, 1935, complaining of loss of vision in both eyes over a period of about six months. The initial loss of vision occurred quite rapidly in November 1934. She consulted an optometrist, who gave her glasses, which did not improve her vision. She was seen by an ophthalmologist (Dr. C. P. Sullivan) in March 1935, who noted at this time that she had cataracts which were not ready for operation. She was given a plus 0.50 sphere in each eye and plus 1.00 sphere added for near vision. Her vision then was 0.5 in each eye. She continued to get worse. She had been taking three capsules of dinitrophenol daily for a period of about a year. She lost 60 pounds (27 Kg.). She stopped taking the drug about two weeks prior to examination.

Examination later revealed the vision 0.2 in each eye.

External ocular examination was negative. Homatropine refraction revealed on retinoscopy R plus 3.00 w plus 0.50 c 60, L plus 2.50 w plus 0.50 c 90. The trial case showed no improvement with the proper lenses. Ophthalmoscopic examination showed many lenticular opacities. The fundi were not seen clearly but were apparently normal.

Slit lamp examination revealed normal corneas and anterior chambers. The lenses showed many subcapsular striate opacities anteriorly, with numerous small white round opacities deep in the central cortex. The posterior cortex resembled a posterior cortical saucer-shaped cataract. It had an intense copper appearance with a zone of iridescence that was quite pronounced. The left lens showed more marked changes than the right.

² Die Cataracta complicata, welche nicht auf Grund jenes Gesetzes der senilen sondern die Folge bestimmter exogener Schäden sind (Cataracta complicata unlike senile cataracts, are the result of definite exogenous injuries).

From the Ophthalmologic Service, Cook County Hospital and the Department of Ophthalmology, Northwestern University Medical School.
¹ Horner, W. D., Jones, R. B. and Boardman, W. W. Cataracts Following the Use of Dinitrophenol. J. A. M. A. 105: 108 (July 13) 1935.

A second case seen by Dr. Sanford Gifford is reported with his permission. Mrs. F., an otherwise healthy woman of 42, had taken dinitrophenol for slight obesity during 1934. The exact dosage could not be ascertained, she had lost 2 pounds a week for several months. Physical examination and blood chemistry were essentially negative. The blood calcium was 9.9 mg and blood sugar was not increased. The drug was stopped in August 1934. Three months later vision was reduced, but was improved by glasses. Two more changes of glasses were made, but in April 1935 she was unable to read with any glasses. When she was first seen by Dr. Gifford, in July 1935, vision in both eyes was reduced to light perception with good projection. Both eyes showed intersegmental cortical cataract, the cortex being white and flaky and the anterior chambers shallow. The right eye was operated on, July 15, operation being uneventful and vision 20/25 at the first test after a needling. Although the patient was of an age when senile cataract might possibly have developed, the rapid course of the bilateral opacities suggests a probable relation to the drug taken. By analogy with other forms of nonsenile cataract, such as that seen in parathyroid tetany, it is not unreasonable to suppose that the lens changes, once begun during administration of the drug, might go on to complete opacity after its discontinuance. In the late stage at which this case was seen, there was nothing characteristic about the clinical picture, a situation that exists also in the late stages of other toxic forms of cataract. In the first case, however, the picture resembled that described by Horner and his associates.

COMMENT

A case is reported of bilateral anterior and posterior cortical cataract in a comparatively young person, coming on suddenly after prolonged treatment with dinitrophenol, with a great loss of vision over a period of less than four months, and showing a marked increase in the hyperopia. The well known fact that the drug causes a tremendous dehydration of tissue may hasten the maturity of lens opacities already present. An important fact is that, as shown by these and other reported cases, cataract may develop on average dosage of the drug, and without any general symptoms suggesting harmful effects. In the second case the opacities were first noted some time after the drug had been discontinued.

303 East Chicago Avenue.

CATARACTS FOLLOWING DINITROPHENOL

PAUL W. KNISKERN, M.D., GRAND RAPIDS, MICH.

Mrs. M. O., aged 37, came, Sept. 18, 1933, for the treatment of obesity. Her past history was unimportant except for a gonorrheal infection earlier in the same year. She had three children, one of whom had congenital cataracts. She had been obese since childhood. Her weight was over 300 pounds and she had not reduced to any extent on diet and thyroid in small doses. She was put on a 1,200 calory diet and given alpha-dinitrophenol, 5 grains (0.3 Gm.) daily, for two weeks. She then took 10 grains (0.6 Gm.) daily for two weeks, followed by two weeks of alternating the larger with the smaller dose. Feb. 21, 1934, she weighed 283 pounds (128 Kg.) and felt well. The dosage was reduced to 6 grains (0.4 Gm.) daily and two months later to 2 grains (0.13 Gm.) daily. From June 6 to July 25 she took 4 grains (0.26 Gm.) and on the latter date was found to be about six weeks pregnant.

During pregnancy the drug was discontinued except for a period of two weeks during which she took 2 grains (0.13 Gm.) daily, beginning Oct. 24, 1934. She had seven antepartum examinations between July 25, 1934 and March 6, 1935. No albumin, sugar or casts were ever found. Her blood pressure was 120 systolic, 78 diastolic on the first visit and 150 systolic 96 diastolic, on the last, with no higher readings between these dates.

She first noted failing vision early in November. Nov. 26, 1934, the ophthalmologist's report was "incipient cataracts, both eyes." Jan. 26, 1935, she was unable to count fingers at 2 feet with either eye. She was delivered of a normal baby, March 8. March 27 her cataracts were pronounced mature and removal

was advised April 18, the right lens was removed by Dr L. O. Grant, who reported it a mature cataract. Vision was brought up to 20/20 with refraction.

COMMENT

Two factors other than the use of dinitrophenol are to be considered in this case: the cataracts formed late in pregnancy and they occurred in a woman who had given birth to a child with congenital cataracts.

SUMMARY

A woman, aged 37, took 1,900 grains (126 Gm.) of alpha dinitrophenol over a period of a little less than a year and at the end of that time developed bilateral mature cataracts in a period of four months.

LATE DEVELOPMENT OF CATARACT FOLLOWING
USE OF DINITROPHENOL ABOUT
A YEAR BEFORE

T. D. ALLEN, M.D. AND V. M. BENSON, M.D. CHICAGO

April 4, 1922, the vision of Miss V. M. B., aged 25, a student at Rush Medical College, was 20/20 + in each eye, with and without a very slight correction for compound hypermetropic astigmatism, fitted after careful refraction with homatropine. The appearance of the eyes was perfectly normal externally and internally. Muscle balance was normal.

In May 1927 a slight change of the glasses was necessary. With these her vision was 20/15 and her near point from 18 to 20 cm. Again no changes were found in the interior of the eyes.

March 22, 1935, at the age of 38 years she complained of clouding of the vision, which had seemed to come on rather suddenly about three weeks before. Accommodation was slightly reduced but there was no essential change in the refraction or in the central fields of vision. When the pupils were widely dilated there was found with the slit lamp to be an irregular, granular sheen on the posterior surface of each lens and a few very fine deposits, like a sprinkling of dust, on the back of each cornea. Also there was a slight atrophy of the pigment border of each iris.

The general medical examination was made by Dr. Fred M. Drennan, who reported one small tonsil stump questionably infected, a basal metabolic rate of -12, blood calcium 10.3 mg. per hundred cubic centimeters of serum and adiposity (weight 196 pounds [89 Kg.]). Dr. Drennan suggested that she take thyroid and anterior pituitary extract. The latter upset her but the thyroid in one-half grain (0.03 Gm.) doses three times a day caused an increase in the basal metabolic rate of about 18 points.

She was seen at frequent intervals, always complaining of increasingly hazy vision. June 4 the vision of the right eye was 20/30 and of the left eye 20/40. July 1 the vision of the right eye was 20/70 and of the left eye 4/200. July 9 the vision of the right eye was 20/70 + and of the left eye the counting of fingers at 2 feet. July 17 the vision of the right eye was 20/30 (see comment) and of the left eye counting of fingers at 1 foot.

June 4 she suggested dinitrophenol as the possible cause. She had been taking this drug in an average daily dose of 0.4 Gm. from Dec. 30, 1933, to early in June 1934, a total of approximately 73 Gm. or 1,460 capsules of 0.05 Gm. each. The drug was taken on a basis of from 3 to 5 mg. per kilogram. It resulted in a loss of weight of 32 pounds (14.5 Kg.). She stopped the drug in June on account of the warm weather but started again in September because she had regained about half the weight she had lost. However, it upset her gastro-intestinal tract so she stopped taking it after a few days and did not start again. She had a little difficulty in seeing (accommodation?) during October 1934.

An interesting comment of hers on July 1, 1935, was that two weeks before the vision of the left eye suddenly improved and for about five days she could see quite well. Then suddenly the vision diminished. July 1, after thorough dilation of the pupils we examined with the slit lamp and made the following comment: Right eye fine granular changes immediately beneath the anterior capsule of the lens. With a very fine beam these changes were seen to begin at an irregular depth immediately

beneath the capsule. There was only a very faint haze in the cortex proper. No distinct nucleus of the lens was seen, and the posterior capsule had the appearance of a granular or hammered copper surface. Left eye, anterior chamber shallow, mother of pearl appearance of the cortex, with a distinct interval between the opaque cortex and the capsule. In each eye, very few fine dustlike opacities on the back of the cornea but no evidence of iritis, and the tension was 17 mm. (Schiotz) in each eye both before and after dilation. (The tension has never been found above 20 mm.)

July 13 the vision of the right eye seemed suddenly to improve and on the 17th it was 20/30. She felt that this improvement was similar to that of the left eye immediately before the vision in that eye became very dim.

Left linear extraction was performed August 6 and right linear extraction August 9 with extremely little reaction and practically no cortex left. On August 12 right vision with sphere +11 cylinder +1 axis 180 = 20/40, left vision with sphere +12 cylinder +1 axis 165 = 20/50. The subnormal vision is easily accounted for by wrinkling of Descemet's membrane.

This patient has taken regularly for the last several years one glass of orange juice or tomato juice beginning therefore before she ever took dinitrophenol and continuing up to the present time.

SUMMARY

There was a history of the ingestion of approximately 73 Gm. of dinitrophenol over a period of about five and a half months with the first evidence of cataract seen nine months after the drug was discontinued. The cataracts developed simultaneously, but one more rapidly than the other, one becoming complete within five months.

PNEUMOCOCCUS (TYPE III) MENINGITIS RECOVERY

REUBEN STEINHOLZ, M.D. AND MORRIS GLEICH, M.D. NEW YORK

Pneumococcus meningitis is a highly fatal disease. Cases of recovery are so rare that the successful outcome of one, particularly a type III, warrants reporting.

A girl aged 7 years, with a normal developmental history and the usual childhood diseases, stuck a rubber eraser from the end of a pencil into her right ear. A roentgenogram revealed this foreign body in the right internal auditory meatus. Under general anesthesia this object was removed five days later. The postoperative course was uneventful. The child was discharged two weeks later with a right purulent otitis media. A right facial palsy was reported six weeks later, lasting for two weeks.

Her present illness began nine weeks after the original trauma, with headache, vomiting and refusal of food. The next day on admission to the hospital she had a convulsion. The temperature was 102 F., respiration rate 40 and pulse 128. She was pale, irritable and drowsy but easily aroused. She lay in bed with her knees and hips flexed and showed marked nuchal rigidity. The pupils were moderately dilated, were equal and reacted to light. No nystagmus or strabismus or facial palsy was noted. The tongue did not deviate from the midline. The left drum was normal but the right drum was absent. There was a small mass protruding from the middle ear. A moderate sanguinopurulent discharge was present. The right mastoid was not tender but hearing from the right ear was completely absent.

The tonsils were moderately enlarged and injected. The heart and lungs were normal. Examination of the abdomen was negative. The Kernig and Babinski signs were absent as well as the knee jerks.

Urine, blood culture and the Pirquet test were negative. The blood count showed 14,600 white blood cells, 79 per cent being polymorphonuclears. Roentgenograms of the lungs and both mastoids were negative. Roentgen examination of the sinuses revealed clouding of the right and left antrums with thickening of the mucosa. Cultures of the right ear were unsatisfactory.

From the Pediatric Department, Harlem Hospital, Dr. Thomas A. Martin, medical director.

Through the lumbar route 25 cc. of cloudy fluid under moderately increased pressure was removed and replaced with 20 cc of antimeningococcus serum. The fluid showed 150 cells, with 80 per cent polymorphonuclears. Globulin and albumin were increased and dextrose was present. No organisms were seen in the smear but culture revealed a type III pneumococcus. This was confirmed by the pneumonia laboratory as well.

Since this report did not arrive for a few days, we continued to use antimeningococcus serum. The next day 10 cc of cloudy fluid was removed with difficulty by the lumbar route, so a cistern puncture was done. Twenty cubic centimeters of cloudy fluid was obtained showing 200 cells, 90 per cent of them being polymorphonuclears. Twenty cubic centimeters of antimeningococcus serum was administered through the cistern puncture and 10 cc intramuscularly.

On this day she had a convulsion lasting ten minutes and involving the left side of the body. The next day she was much brighter and answered questions but still complained of headache. The right knee jerk was now present, the neck still rigid and the temperature 100 F. Another cistern puncture was performed and 20 cc of cloudy fluid was obtained. This was replaced by 20 cc of antimeningococcus serum. Another 20 cc of antimeningococcus serum was given intramuscularly.

On the third day after her admission the blood showed specific pneumococcus type III antibodies. Twenty-four hours later the temperature was normal, nuchal rigidity was diminished and the child sat up and played. Improvement continued rapidly and in a few days nuchal rigidity had completely disappeared.

The use of type III antipneumococcus serum was discouraged on the third day when the laboratory reported pneumococcus type III in the spinal fluid. At this time the child was clinically much improved and showed pneumococcus type III antibodies in the blood.

A lumbar puncture done two weeks after admission was perfectly clear with a cell count of 4 lymphocytes. The neurologic examination was negative.

This case of pneumococcus meningitis is probably of otitic origin. The facial palsy and the left-sided convulsion point to a chronic otitis media as the exciting cause. The brain and meningeal involvements were evidently localized rather than widespread. Enough of the infection spread to the subarachnoid space to produce a cloudy spinal fluid.

The child did not succumb to the infection because it was localized and the type of pneumococcus was attenuated. Two laboratories reported that the mice infected with the specimens of spinal fluid from the patient did not die. This verified the low virulence of the organism.

Most authorities, as Osler, Holt, Neff and Kolmer report that pneumococcus meningitis is invariably fatal. The few isolated cures reported were instances in which antipneumococcus serum or ethylhydrocupreine had been tried.

Ratnoff¹ reported a cure of type III pneumococcus meningitis treated with ethylhydrocupreine. Kolmer² used ethylhydrocupreine in the proportion of 5 cc. of a 1,000 solution in physiologic solution of sodium chloride per kilogram of body weight, giving two injections a day for four days. Weinberg³ reported the cure of a case of type III pneumococcus meningitis, using the Nott treatment, i. e. retention enemas of potassium permanganate, 4 ounces (120 cc.) every four hours (2 grains [0.13 Gm.] of potassium permanganate to 1½ pints of water). Harkavy⁴ reported a type I case cured by type I serum. Globus⁵ reported a type I case cured by forced drainage through cistern and lumbar puncture routes.

ELECTROSURGICAL EXTIRPATION OF XANTHOMA

REPORT OF TWO SEVERE CASES

LEWIS J GORMAN SILVERS M.D. NEW YORK

Two sisters, S and A R, identical twins, aged 36, complained of the unsightly appearance of the deep yellow patches completely encircling their eyes. The family history was entirely negative. No one in their family of six, all older, had ever suffered from this type of disfigurement. Prior treatment consisted of the application of a chemical caustic, probably monochloroacetic acid according to the method of McGuire,¹ at the Skin and Cancer Hospital. The prompt recurrence of the chamois-like patches with a deeper yellow hue followed after several months' treatment and observation.

Xanthoma palpebrarum planum is a fatty degeneration of the superficial fibers of the orbicularis oculi muscle, as clearly shown by the work of Pollitzer.² The etiology is as yet unknown. Pathologically the epidermis, cutis, hair follicles and glands are normal, however, the greater part of the cutis is

Fig 1—Appearance prior to treatment.

packed with cell-like masses known as xanthoma cells. These so-called cells are fragmented and degenerated remains of muscle fibers with proliferated sarcolemma nuclei. Hence it may be noted that the xanthoma cell is not a cell at all.

The most satisfactory treatment employed by Hazen³ is electrolysis, the negative pole of the galvanic current being used. In my own hands galvanism was often followed by recurrence, and so the advantages of a definite controllable high frequency current became manifest. Infiltration anesthesia is executed with a very fine hypodermic needle over the area to be desiccated. A small, pointed needle electrode connected to the Oudin or monoterminial high frequency outlet is employed. A current strength that will produce a millimeter spark on fulguration is essential. The spark must not be too intense, as scarification might result. The degenerated, fatty

Fig 2—Appearance of patient after electro-surgical extirpation. No sign of recurrence after more than one year's follow up.

fibers are then thoroughly desiccated by the penetrating active electrode. The concomitant destruction of the dermal layers is minimized by the cooling effect of the infiltrating anesthetic. The biterminal or coagulating current must be sedulously avoided, as scarring and pitting might ensue. The strength of the current remaining constant, the time required for total extirpation depended on, first the amount treated at each sitting and, secondly, the total number of patches present. Treatments were entirely ambulant, being given weekly to each lid alternately. Complete eradication of the chamois-like growths was accomplished in about ten sittings without interfering with the patient's normal activities.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION
OF THE FOLLOWING ARTICLE. H A CARTER Secretary

THE USE OF HEAT IN DISEASES OF THE NERVOUS SYSTEM

CLARENCE A PATTEN, MD
PHILADELPHIA

Heat is frequently used in the treatment of both organic and functional nervous disease and provides a very effective therapeutic agent. It is used in many ways both locally and generally.

HEAT IN THE PSYCHOSES

Heat is generally used systemically in the treatment of the psychoses and is usually of considerable advantage if used over a long period of time. It is definitely of greater value in the agitated and maniacal mental states because of its sedative effect, but it is not particularly effective in the depressions except occasionally in agitated melancholia. In the acute depressions of the manic depressive psychoses it may be of slight value, but experience has shown that it does not influence the course of the disease. The means by which heat is applied in mental states in the order of their efficacy are: 1 The continuous hot bath, 2 The cold pack, 3 The warm pack, 4 Cabinet sweats, 5 Conditioned heat.

The continuous hot bath is used particularly in cases of maniacal excitement and maintains a steady temperature of about 96 to 98 F and sometimes more. Such baths have been employed in mental hospitals for a considerable number of years and are a necessary part of the modern hospital's equipment for handling excitable patients. Large tubs are used of sufficient length to accommodate the patient comfortably. They are frequently equipped with canvas slings, which are used to keep the patient from contact with the bottom of the tub. The temperature is controlled by a mixer, which regulates the temperature of the water. The attendant, however, must always use a bath thermometer as a check on the thermometer in the mixer. Patients are kept in the continuous bath for various periods of time, depending on their condition. No clothing is worn and any form of restraint is unwise. The soles of the feet and the palms of the hands must be well greased before the patients get into the tub. Many patients receive their meals while in the water, sleep there, and may be kept in the tub for days at a time. The continuous bath offers a means of inducing sedation which is unparalleled so far as physical measures are concerned, and by this means violent patients are controlled more rapidly than by the use of drugs. A caution is to be observed in that a nurse or attendant must be constantly present during these baths to see to it that no harm comes to the patient and that the water is kept at the desired temperature.

In case a properly constructed continuous bath is not available for excitable patients an ordinary tub can be used for short periods frequently repeated, provided a nurse or attendant constantly watches the temperature of the water and keeps it at the desired degree of heat.

Cold packs, which are really forms of heat therapy, are given in the following manner. The full length of

a mattress is covered by a rubber sheet, over which are placed two or three woolen blankets. A sheet is wrung out in cold tap water and spread over the topmost blanket and the patient laid on it. The sheet is wrapped about the patient and folded over the feet and about the shoulders. The topmost blanket is brought up over the patient and another blanket is spread over him and tucked beneath him. The second lower blanket is folded over the patient and another one spread over him and tucked beneath him. The third, or even a greater number of blankets, is folded about the patient in the same manner. An ice bag is placed to the patient's head, which is supported by a small pillow, and the patient is encouraged to drink water freely. The patient is allowed to remain in the pack until he has perspired freely and usually for a considerable period after that, depending on his condition. Cold packs offer a very effectual means of restraint in excited cases, as well as producing a marked sedative action. Warm packs are used in the same manner as cold packs except that the sheets are not wetted and the blankets are carefully warmed beforehand. Certain patients, however, who are put in a pack only when they are markedly disturbed come to have the idea that it is a form of punishment for them. It is best to use the packs or even the baths at stated times to obviate this reaction.

Neither cold nor warm packs are used in the presence of circulatory or cardiac derangement or when the patient is in a very weakened condition. During the time the patient is in a pack a nurse must be in constant attendance, observing the color and pulse rate of the patient. In case of an abnormal reaction the patient must be immediately removed from the pack. When the treatment is to be terminated, one blanket is removed at intervals so that the patient cools down gradually. A pack is usually followed by a shower and then an alcohol rub or a light massage.

Electrical cabinet baths are frequently used for cooperative mental patients for the purpose of obtaining the effects of varying degrees of heat over a short period of time as well as elimination through free perspiration. Usually the cabinet is followed by a needle spray of warm and then cold water for its tonic effects and after that massage may be employed.

At the present time certain equipments are being experimented with for the purpose of giving patients conditioned heat. These consist of appliances much like respirators and so constructed that the patient lies wholly within them except that the head protrudes through an opening at one end. The body is thereby subjected to a uniform heat. The temperature of the air, which is moist, is gradually increased until the patient's temperature reaches the desired point, which may be anywhere from 102 to greater degrees. By means of this type of apparatus, effects are obtained similar to those following other methods for the application of continuous heat, with the added advantage of a moistened air. The contraindications are the same as those for the cold and warm packs. Conditioned heat, however, is probably less used in the psychoses than are the continuous tubs, for the obvious reason that a part of its success depends on the full cooperation of the patient, which cannot be obtained as a rule in excited patients when it is most needed.

Various forms of heat therapy are used in the organic psychoses, particularly dementia paralytica. In dementia paralytica the continuous baths are helpful

when the patients are markedly excited, but only for the sedative effects. For the purpose of combating the disease, more vigorous heat therapy is needed. This is accomplished by raising the body temperature to 104, 106 or even higher for a period of hours. Some form of diathermy may be employed but in using diathermy there is always danger of producing burns where the electrodes are placed. Cabinet bakes, electric heat blankets and the conditioned heat apparatus previously mentioned are quite effective.

HEAT IN THE PSYCHONEUROSES

The systematic use of physical therapy in the treatment of the psychoneuroses had its inception under the direction of Dr. S. Weir Mitchell. In the so-called rest cure named after him the use of electric light baths, combined with hydrotherapy, massage and moderate exercise, is of great benefit. The same causes that operate in the production of physical disease in one patient may produce a nervous or mental disorder in another, therefore the physician should be guided by the same general principles and by a balanced conception of therapy.

In the psychoneuroses the so-called tonic electric cabinets given every day and followed by hot and cold contrast showers afford a great stimulus to the patient and in addition occupy a certain part of his time, which is of importance. Hydrotherapy in the form of hot and cold showers alone can be given daily. The method of application of these procedures has been commented on under arthritic and rheumatoid conditions, but it must be again emphasized that electric "baking" with hydrotherapy is only a part of the general treatment of the neuroses and dependence must not be placed on it alone.

HEAT IN ORGANIC NERVOUS DISEASE

Heat is of the greatest value in inflammations of the peripheral nerves and in vascular diseases in which implication of the nervous system is evidenced by pain of greater or lesser severity. In the various neuritides, in neuralgia, in radiculitis or in inflammation of any of the nerves in the limbs, heat, and particularly dry heat, allays the inflammation and pain. In neuritis in certain areas care must be taken to give a sufficient amount of treatment, for the penetration must be deeper in some parts than in others. Heat is only one mode of treatment, as frequently a neuritic condition is part of an arthritis. Electrical treatment, principally in the form of diathermy, may be more efficacious. In cases of toxic infectious multiple neuritis, heat is applied to the extremities by attaching electric light bulbs to the central pole of a cradle placed over the patient. In these cases any degree of heat may be used that is desired and most patients find it very comfortable. The cradle serves the additional purpose of keeping the bedclothes off the patient's sensitive limbs. This form of heat therapy may also be used for a neuritis or vascular disorder localized to one limb and, by continuous application, may afford a progressive relief from the painful symptoms.

In certain vascular diseases of the limbs, such as erythromelalgia, Raynaud's disease, thrombo-angitis obliterans, thrombophlebitis and endarteritis obliterans, dry heat applied to the diseased parts more or less constantly over a period of days causes an alleviation of the symptoms of pain. It is not a cure but is used mainly for the relief of pain and for improvement of

the circulation. The modern operation of sympathectomy offers much more hope of permanent relief in certain types of cases.

Even in chronic diseases of the nervous system, such as hemiplegia or lateral sclerosis, when the limbs are spastic, heat will decrease the spasms and contractures, at least for a time and will moderate other symptoms. In chorea of the acute variety, provided no heart disease exists, any method of applying heat generally will be found to produce remarkably sedative results. Most frequently the continuous tub is employed, but only for an hour or two at a time.

Council on Pharmacy and Chemistry

REPORT OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT
PAUL NICHOLAS LEECH, Secretary

ROSSIUM NOT ACCEPTABLE FOR N. N. R.

Rossum, which is stated to be Di-phenylmethyl-pyrazolonyl, was presented for the Council's consideration by the Medico Chemical Corporation of America. The following structural formula was presented as representing the composition of the product:

The product is marketed in capsule form and is advertised for use in the treatment of drug addiction.

With the information concerning the product, the firm submitted the following material:

1 A typewritten copy of a paper by Dr. Ivan I. Ostromis lensky, entitled "Morphinism and Anaphylactic Shock," which appears to have been read at the meeting of the Russian Medical Society of New York, Nov. 25, 1931.

2 A discussion of the chemistry of Rossum, to which is attached a statement, a part of which will be quoted.

3 A Preliminary Report having the title "Rossum," and a subtitle "A New Therapy for Drug Addiction Morphinism Heroinism-Codemism-etc."

4 (a) Several tables showing the activity of Rossum and of insulin in antagonizing the effects of an antigen in guinea pigs. (b) A similar study with forty-one other preparations.

In the absence of any satisfactory evidence in support of the therapeutic claims made for Rossum, this report will present only so much as may be necessary to give a true indication of the claims made for it. The following is taken from Ostromis lensky's paper on "Morphinism and Anaphylactic Shock."

"The theory is that when morphine preparations are injected daily in man for a sufficient length of time there appears in the blood a new kind of protein—an auto-protein which acquires the properties of an antigen. Although formed in the body this protein acts on the organism in the same manner as a foreign protein causing the formation of a specific antibody. The quantity of the specific auto-antigen circulating in the system of morphine addicts gradually increases. Therefore as a rule, a morphine addict requires a gradual increase of his daily dose of the drug. The basic premises and conclusions of this theory may be formulated as follows:

1 The symptom-complex appearing in morphine addicts at the withdrawal of the drug should be considered as the symptom-complex of the anaphylactic shock.

2 An individual who takes morphine daily in about three weeks usually becomes an addict supposedly at the time when the corresponding specific antibody is formed in his system.

3 The addict's imperative need of morphine can be explained through the ability of morphine to prevent the possibility of chemical reaction between the antigen and its antibody. To avoid the anaphylactic shock,

hence prevent withdrawal symptoms one must replace the morphine by a chemical substitute preventing the combination between antigen and antibody

4 A morphine addict who has stopped taking morphine continues for a long time to be a carrier of the specific antibody. Hence, he may be said to remain in a state of potential addiction for an indefinite length of time. Subsequently, on the very first injection of a quite insignificant dose of morphine, if the antibody still exists there appears again in the system of the addict a specific autoantigen which provokes the inevitable relapse

5 At any given period of the disease, a definite quantity of the antigen is circulating in the system of morphine addicts. Therefore at any given period of the disease an addict always requires a definite and precise quantity of morphine which suffices to neutralize all of the auto-antigen present in the system"

The following statement is attached to the second communication, "The Chemistry of Rossium"

"Clinical studies of this preparation have been conducted from 1931 to 1934 particularly at Blythwood Sanatorium Greenwich Connecticut Stony Lodge Ossining New York St Michael's Hospital Newark New Jersey, and Towns Hospital, New York City

"Clinical observations show that Rossium checks the most severe symptoms of withdrawal in drug addicts (Morphinism Heroinism Codeinism etc) and markedly decreases all other symptoms

"The following physicians are amongst those who have had an opportunity to administer Rossium in the cases mentioned

"Dr Alexander Lambert, 43 East 72nd St. New York City

Dr P R Vesic, % Stony Lodge Sanitarium Ossining, N Y

Dr Silkworth % Towns Hospital 292 Central Park West New York.

"Prof Dr Ostromislensky 256 West 116th St. New York

Dr M W Openchowski together with Dr W J Donahue 324 Parker St. Newark and City Hospital as well as St. Michael's Hospital Newark.

Dr N N Harin 324 Parker St Newark, N J

The Council's secretary wrote to Dr Lambert calling his attention to the fact that his name was being used in connection with Rossium. Dr Lambert replied

I have your letter of recent date regarding my name in the use of Rossium

I did not give permission for any such use of it as you mention that is entirely reprehensible, and I have so written to the Medico Chemical Corporation of America

I have been clinically trying Rossium to alleviate the withdrawal symptoms of morphinism. This it does exceedingly well but this is not the eradication of the morphine habit which is quite another story

Thank you for drawing my attention to this otherwise I should not have heard of it

The letter of the Council's secretary, to which this was a reply, read as follows

"We are receiving many inquiries from state hospitals health commissioners, etc concerning letters sent out by the Medico Chemical Corporation of America on behalf of Rossium. Paragraphs appear in these letters somewhat as follows

We wrote you that DR ALEXANDER LAMBERT of New York is using this drug with great success and we now have other clinical data to substantiate our claims. Animal experimentation as well as clinical experiments with humans have proven the non-toxicity of this drug which incidentally is non-habit forming

It seemed advisable for this office to obtain from you a statement as to whether or not your name is being used in this connection with your permission. Your name is always capitalized whereas no other part of the paragraph is so emphasized

In the presentation submitted by the firm (which accompanied the firm's letter of Oct. 29, 1934), the following statement occurs under "Therapeutic Indications"

Drug addiction disease (Morphinism Heroinism etc.) Rossium checks the most severe symptoms of withdrawal in drug addicts and markedly decreases all other symptoms. In cases of cocaine addiction Rossium is inactive

The tables submitted by the firm support the statement that Rossium prevents the symptoms of anaphylactic shock in guinea-pigs previously treated with an antigen, and according to the theory of Ostromislensky this must be true if it is valuable in reducing withdrawal symptoms (anaphylactic shock) in addicts

A physician in charge of the allergy laboratory in a large hospital informed the Council's referee that he knew of nothing to support the theory that when morphine is injected, an auto-protein having the properties of an antigen appears in the blood of man.

The Council cannot accept the fifth statement in the theory of Ostromislensky that at any given period of the disease [morphinism] a definite quantity of the antigen circulates, requiring a definite and precise quantity of morphine to neu-

tralize all of the auto-antigen present in the system, because it is well known that morphine addicts who take excessive daily amounts of morphine (up to 30 grains or more daily), may have the daily dose reduced rapidly without serious inconvenience, until only a very small fraction of the customary dose is taken daily

Rossium has been known for three years, and has been used in a number of hospitals and by a number of physicians, but no convincing therapeutic evidence in support of the claims has been submitted, it must be remembered that therapeutic evidence means more than unsupported statements. Furthermore, the directions for the use of Rossium include the use of hypnotics and other sedatives such as are commonly used in the treatment of the withdrawal symptoms. Finally, the studies of toxicity are wholly inadequate, and the Council is not convinced that the doses recommended are always harmless.

In the absence of convincing evidence concerning the therapeutic value of Rossium, the Council, without further consideration of its name, chemical properties, pharmacology, etc., declared the product unacceptable for inclusion in New and Nonofficial Remedies

A statement of the Council's consideration was transmitted to the Medico Chemical Corporation of America in conformance with the Council's custom of giving a firm the opportunity to comment on the report before publication. The firm's reply contained nothing to change the attitude of the Council with regard to acceptance of Rossium, and the firm was so informed. The firm subsequently submitted a further reply which likewise contained nothing to warrant a change in the Council's action. In its letter the firm made the following statement

We are well aware of the fact that we are not precluded from presenting additional evidence to the Council and then get the desired admission but wish to direct the attention of the Council to the fact that the mere publication of the above conclusion of the Council under the above circumstances may cause this applicant unreparable damages and greatly handicap the development of its business without any fault what soever on its part

It thus admits that additional evidence is necessary. The Council desires to point out that its duty is first to the physician and to the public. It would be remiss were it not to inform physicians concerning the status of a preparation which is being actively exploited, for which there is not sufficient evidence to justify claims made, and in the use of which there is the possibility of as yet unknown untoward effects

Subsequently the firm presented a paper entitled 'Preliminary Clinical Report—ROSSIUM, A New Treatment for Drug Addiction' by Herman E Bauer, M.D. The Council found that this study, which was conducted without careful control, offered no reason for changing its decision to publish the foregoing statement.

In connection with the matter of control evidence for preparations of this sort the Council recalls that two highly qualified men reported that Narcosan was of great value in the treatment of morphine addiction (*M J & Rec* 124 764 [Dec. 15] 1926). They reported on the treatment of 219 men and 147 women, a total of 366 patients in a special ward. Nevertheless within a little more than two years, the Mayor's Committee of New York on Drug Addiction, reported that Narcosan treatment was given to sixty-eight patients, that the results were clear-cut, that there was a greater occurrence and intensity of all the symptoms mentioned in those treated with Narcosan, that there was more marked restlessness and muscular twitching and particularly a greater intensity in vomiting, diarrhea, cramps, and in general prostration. In short, symptoms occurring in patients receiving Narcosan were more severe than in those not receiving Narcosan, and there was no advantage shown in recuperation after the withdrawal period of those receiving Narcosan.

That record could be duplicated in essentials with reference to many so-called cures for morphine addiction, and the Council cannot accept any study in which careful controls are not conducted, and it cannot accept a study of a small number of cases, even with satisfactory controls

The Council authorized publication of this report declaring Rossium unacceptable for New and Nonofficial Remedies

CELLU SLICED PINEAPPLE PACKED IN WATER WITHOUT ADDED SUGAR OR SALT

Distributor—The Chicago Dietetic Supply House, Inc., Chicago

Packer—Hawaiian Pineapple Company, Ltd, San Francisco

Description—Canned cooked sliced Hawaiian pineapple packed in water without added sugar or salt.

Manufacture—The method of manufacture is essentially the same as for Doles 1, 2 and 3 Hawaiian canned pineapple products (THE JOURNAL, April 8, 1933, page 1106), with the exception that the fruit is packed in water

Analysis (submitted by distributor) —

Calories—0.5 per gram 14 per ounce

Claims of Distributor—For diets in which sweetened fruit is proscribed

COFLO—McMATH PROCESS PARTIALLY DEFATTED COOKED COTTONSEED FLOUR

Manufacturer—Traders Oil Mill Company, Fort Worth, Texas

Description—Partially defatted, cooked, pulverized, dehulled cottonseed

Manufacture—Selected cottonseed obtained from the cotton gins is further delinted and hulled. The decorticated seeds are pulverized and are cooked in a definite quantity of water for from seventy to ninety minutes in steam jacketed cookers. During the last ten minutes the moisture level is reduced to 12 per cent. The temperature during the first fifteen minutes is rapidly raised to 102 C. and subsequently gradually to 108 C. The cooked material is defatted in hydraulic presses to about 9 per cent fat content, the resulting cake is ground and the flour separated by air flotation.

The temperature and moisture are controlled in the manufacturing process to convert the gossypol content to a nontoxic form.

Analysis (submitted by manufacturer) —

	per cent
Moisture	5.5
Ash	6.0
Fat (ether extract)	9.4
Protein (N × 6.25)	50.0
Crude fiber	2.1
Carbohydrates other than crude fiber (by difference)	26.0

Calories—3.9 per gram 111 per ounce

Vitamins—Biologic assay shows the flour to be a good source of vitamin B

Differences Between Gossypol from Raw and Processed Cottonseed Flours and Nontoxicity of Gossypol of Processed Cottonseed—

1 Absorption spectrum readings taken across the visible part of the spectrum of recrystallized dianiline gossypol prepared

from the ethyl ether extract of the raw and processed cotton seed flours are distinctly different and individual

2 Recrystallized dianiline gossypol prepared from raw cottonseed flour is readily distinguishable crystallographically from that prepared from the processed cottonseed flour

3 Feeding tests with guinea-pigs and white rats show that the processing inactivates any toxic materials that may be present in the raw cottonseed

4 Clinical tests in which twenty-five nurses and two doctors in a hospital were fed 60, 30 and 20 Gm daily for eight weeks showed that the processed cottonseed flour was well tolerated with no untoward effects

Claims of Manufacturer—Rich in high quality protein, and a good source of vitamin B. Free from toxic form of gossypol.

LULLABY

Distributor—Milk Foods, Inc., San Francisco

Manufacturer—Golden State Co., Ltd., Newman, Calif

Description—Sterilized, concentrated, homogenized mixture of milk, cream, dextrose and lactose

Manufacture—Milk and cream from state accredited dairies are mixed in definite proportions and heated. Lactose and dextrose are added in definite quantities. The mixture is pasteurized at 88 C., concentrated under vacuum to the desired percentage of solids, homogenized, cooled, automatically canned and processed to sterility at 117 C.

Analysis (submitted by distributor) —

	per cent
Moisture	62.1
Total solids	37.9
Ash	1.1
Fat (ether extract)	10.5
Protein (N × 6.38)	5.2
Carbohydrates (by difference)	21.1
pH	6.4

Calories—2.0 per gram 57 per ounce.

Claims of Distributor—A liquid food for infants deprived of breast milk, to be fed under the direction of a physician. Diluted with two volumes of water, it resembles human milk in percentages of fat, protein, carbohydrate and total minerals (ash)

CHIPPEWA FREE RUNNING SALT

Manufacturer—The Ohio Salt Company, Wadsworth, Ohio.

Description—Table salt containing added magnesium carbonate (1 per cent)

Manufacture—Salt brine is treated with sodium carbonate largely to precipitate out calcium and magnesium salts. Insoluble matter is allowed to settle out, the brine is filtered and is evaporated under vacuum, and the crystallized salt is separated, dried, screened, admixed with magnesium carbonate (1 per cent by weight) and automatically packed.

Analysis (submitted by manufacturer) —

	per cent
Moisture	trace
Calcium sulphate	0.8
Calcium chloride	0.06
Magnesium carbonate	1.0
Sodium chloride (by difference)	98.1

Claims of Manufacturer—For all table and cooking uses. The added magnesium carbonate tends to preserve 'free running' qualities.

(1) COLONIAL WHEAT BREAD

(2) COLONIAL WHEAT BREAD AND WHITE BREAD, SLICED

MADE OF WHOLE WHEAT FLOUR AND WHITE FLOUR

Manufacturer—Colonial Baking Company, Cedar Rapids and Des Moines, Iowa

Description—(1) Sliced and unsliced wheat bread made by the sponge dough method (method described in THE JOURNAL, March 5 1932, p. 817) prepared from water, whole wheat flour, flour, sucrose, powdered skim milk, yeast, salt, lard and a yeast food containing calcium acid phosphate, ammonium sulphate, sodium chloride, potassium bromate, potassium iodate, corn starch and malt. (2) Combination package of Colonial White Bread and Colonial Wheat Bread, sliced

JUNKET POWDER CARAMEL FLAVOR

Manufacturer—Chr Hansen's Laboratory, Inc., Little Falls, N Y

Description—Dessert powder containing sugar, caramel, calcium glycerophosphate, vegetable gum, true maple concentrate, and the Junket enzyme.

Manufacture—The method of preparation is the same as described for Junket Tablets (Not Sweetened or Flavored) and Junket Powder (With Sugar and Flavor) Vanilla, Chocolate, Lemon, Orange, Raspberry and Coffee Flavors (THE JOURNAL, Sept. 30, 1933, p 1076)

Analysis (submitted by manufacturer) —

	per cent
Moisture	0.5
Ash	2.0
Fat (ether extract)	0.1
Protein (N X 6.25)	0.1
Sucrose	96.8

Calories—3.9 per gram 111 per ounce

RELIANCE COFFEE

Manufacturer—Reliance Pure Foods, subsidiary of National Grocery Company, Seattle, Wash

Description—Coarse ground roasted coffee.

Manufacture—Green American, Hawaiian and African coffees are cleaned, blended, roasted under automatic heat control, chilled, ground, and mechanically packed in glass jars, which are sealed under "vacuum"

Analysis (submitted by manufacturer) —

	per cent
Moisture	3.6
Soluble solids	21.5
Ash	3.6
Petroleum ether extract	15.6
Total nitrogen	2.1
Reducing sugars as invert sugar	0.5
Sucrose (copper reduction method)	1.4
Caffeine	1.4
Crude fiber	15.9
Total acidity	4 cc. 0.1 N alkali per gram of coffee

Claims of Manufacturer—Sealed in "vacuum" to retain freshness and flavor

- (a) GRIDLEY FAST FROZEN VANILLA ICE CREAM
- (b) GRIDLEY FAST FROZEN CHERRY ICE CREAM
- (c) GRIDLEY FAST FROZEN MAPLE NUT ICE CREAM
- (d) GRIDLEY FAST FROZEN MINT ICE CREAM
- (e) GRIDLEY FAST FROZEN PEACH ICE CREAM
- (f) GRIDLEY FAST FROZEN PISTACHIO NUT ICE CREAM
(ADDED ALMOND FLAVOR)
- (g) GRIDLEY FAST FROZEN STRAWBERRY ICE CREAM

Manufacturer—Gridley Dairy Company, Inc., Milwaukee

Description—(a) Prepared from a pasteurized homogenized mixture of evaporated milk, sweet cream (26 per cent), sucrose, egg yolk, vanilla extract and gelatin. Contains not less than 13 per cent milk fat

(b) Same as (a) with added cherries and sugar

(c) Same as (a) with added maple syrup and pecan nuts

(d) Same as (a) with added mint emulsion prepared from U S P oil of peppermint glycerin and U S Department of Agriculture certified color

(e) Same as (a) with added fresh peaches and sugar

(f) Same as (a) with added pistachio nuts, almond extract and U S Department of Agriculture certified color

(g) Same as (a) with added frozen strawberries, sugar and U S Department of Agriculture certified color

Manufacture—Formula quantities of the ingredients of the basic ice cream are mixed pasteurized by the holding method

at 66 C for thirty minutes, homogenized, cooled to 4 C., stored in brine-jacketed glass-lined storage tanks and held at 0 C. After twenty-four hours the mix is drawn into ice cream freezers, frozen at -6 C. and automatically packaged. The packaged ice cream is hardened at from -34 to -45 C

Brick ice cream is automatically packed in waxed paper, bulk ice cream in cleaned cans. The ice cream is transported in refrigerated trucks (-16 to -21 C)

The various types of ice cream are prepared by adding appropriate flavors, fruits, nuts, etc., in definite proportions to the basic ice cream mix.

* Journal of Agricultural Research 7:301 1916

Calories—0.3 per gram 9 per ounce

Claims of Manufacturer—A special purpose food for diets restricted in dextrose formers yielding 17 Gm. of dextrose per hundred cubic centimeters. Contains little food value. High in indigestible material

CELLU JUICE-PAK STRAWBERRIES

PACKED IN UNDILUTED JUICE WITHOUT ADDED SUGAR

Distributor—The Chicago Dietetic Supply House, Inc., Chicago

Packer—Eugene Fruit Growers Association, Eugene, Ore

Description—Processed stemmed strawberries, packed in undiluted juice without added sugar

Manufacture—Ripe strawberries are placed in small containers to prevent crushing, conveyed to the factory, stemmed, graded according to size, inspected for removal of foreign material, spray washed, packed into cans and covered over with undiluted juice expressed from other strawberries. The treatment thereafter is essentially the same as for Cellu Juice-Pak Red Raspberries (THE JOURNAL, May 4, 1935, p 1606)

Analysis (submitted by distributor) —

SPECIFICITY OF STAPHYLOCOCCI

In view of the frequency of acute and chronic staphylococcal infections and the promising results of specific therapy, the recent work of Julianelle and Wiegand¹ is significant. In the first of their series of studies the occurrence of serologic types of staphylococci was investigated. The agglutination reaction, they found, presents an uncertain and inconclusive method for distinguishing immunologic types among the staphylococci. In the determination of immunologic specificity of other bacteria, this property is frequently associated with the polysaccharide fraction of the cell, therefore a similar method was tried with the staphylococci. Precipitation tests were made with a number of purified carbohydrates derived from different strains of staphylococcus. On the basis of precipitation of the purified carbohydrates in antibacterial serums, staphylococci are sharply separable into two distinct types. Nine, isolated from different human infections and therefore considered virulent, fell into one type designated A, and the remaining seven, all isolated from nonpyogenic sources and therefore regarded as avirulent, fell into the second type, called B. While the carbohydrates of type A and type B staphylococcus are precipitated in homologous immune serums, they do not precipitate in antipneumococcus types I, II or III serums or anti-Friedländer types A, B or C serums or in antityphoid serum. It is obvious, therefore, that the carbohydrates are genuinely specific of staphylococcus. It was found possible, furthermore, to employ crude extracts of the bacteria for typing purposes in order to avoid the slow and laborious method of obtaining the relatively purified carbohydrate.

Also the chemical nature of the soluble specific substances was investigated. Chemical differences between type A and type B carbohydrates (probably not chemically pure) were demonstrated. The specific optical rotation of type A was +67, as compared with +69.4

for type B. Following hydrolysis, type A yielded 26.1 per cent reducing sugars, of which 17.8 per cent was fermentable and 24.32 per cent was nonfermentable. Type B, on the other hand, yielded 38.84 per cent reducing sugars, of which 35.01 per cent was fermentable and 3.87 per cent was nonfermentable. Moreover, the simple sugar of type B seems to be dextrose, while that of type A remained undetermined but suggests, because of its crystalline formation, a different structure. The immunologic specificity of both polysaccharides is dissipated as hydrolysis proceeds.

In the final paper of this group the authors studied the interrelationships of the cell constituents. A study of the antigenicity of the polysaccharides of staphylococcus indicated that, in the condition originally used, they possessed no antigenic properties if the failure to stimulate agglutinins or precipitins in rabbits is accepted as a measure of antigenicity. Acetylation or adsorption of the carbohydrates on colloidal particles does not render them antigenic. They may be employed, however, to elicit immediate, type specific skin reactions in patients with staphylococcal infection. In contrast, the protein constituent does evoke an antibody response in rabbits. In hypersensitive persons the protein causes a species specific, delayed, inflammatory skin reaction.

The fundamental investigations reported should find an almost immediate practical application in the use of staphylococcus toxoid in clinical staphylococcal infections. The further usefulness is not yet clear but should be manifold.

PRIMARY CARCINOMA OF THE LUNG

The recent literature abounds with references to carcinoma of the lung. Although there is only one reference under the subject of lung cancer in volume 5 (1920) of the *Quarterly Cumulative Index*, there are forty-one in volume 16 (1934). The increasing interest is due to the alleged rising incidence of cancer of the lung and to improvement in surgical technique, which offers a cure of the disease in its early stages. To determine the characteristics and malignant potentialities of different types of carcinoma of the lung, Olson¹ studied sixty-nine cases at the Mallory Institute of Pathology at the Boston City Hospital and classified them on the basis of the microscopic morphology. Investigators have not followed a uniform method in the classification of lung cancers. The older writers divided their cases into tumors arising (a) from the epithelium lining the bronchi, (b) from the epithelium that is said to line the pulmonary alveoli, and (c) from the epithelial cells that form the mucous glands. The more recent writers have suggested a classification of these tumors from a histologic point of view. In 1912 Adler² stated that most lung carcinomas were bron-

2 Adler Isaac. Primary Malignant Growths of the Lungs and Bronchi. New York: Longmans Green & Co. 1912.

chogenic in origin. Fried³ reviewed the subject recently, concluding that all primary lung carcinomas originate from the mucous membrane lining the bronchi. Olson likewise believes that if nonbronchiogenic carcinomas of the lung exist they are rare. He classified histologically into three main groups the sixty-nine cases that came to necropsy: squamous cell carcinomas, adenocarcinomas and undifferentiated carcinomas. The squamous cell carcinomas comprised 42 per cent of the cases, and 28 per cent of them showed the characteristic epithelial "pearl" formation. These tumors were single, gray or white solid masses in 75 per cent of the cases. Multiple masses in one lung were found in only 8 per cent. Areas of tumor necrosis were relatively infrequent. The adenocarcinomas comprised 24 per cent of the entire series. Their chief distinguishing feature was the secretion of mucus and their resemblance to bronchial mucous glands. Since more than half of them showed definite secretory function, this group was subdivided into mucinous and nonmucinous adenocarcinomas. The resemblance of the mucinous type of adenocarcinoma to bronchial mucous glands, and the presence of a mucoid secretion in the alveoli, mark them as a characteristic lung carcinoma. Careful search in the adenocarcinomas nearly always revealed scattered cells in secretory phases, and their metastases in the majority of instances showed mucinous secretion. Grossly, the adenocarcinomas usually appeared as gray, firm, scirrhous tumors with scattered areas of softer yellowish tissue showing visible mucus. Necrosis was uncommon in this group of tumors.

The undifferentiated group of lung cancers was composed of "small cell" tumors, which in the past were often called sarcomas. They have been shown recently by several investigators to be really carcinomas. Of the total series of sixty-nine cases, 33 per cent were of the undifferentiated small cell type. The primary tumor in this group was a mass at the hilus in 65 per cent of the cases, while a secondary or primary bronchus was involved or occluded in 100 per cent. Only 43 per cent of them could be localized by lobes. The entire left lung was infiltrated in 9 per cent and the entire right lung in 4 per cent. The primary bronchi were involved in more than twice as many cases as in either of the other two types of tumors. Grossly, the undifferentiated carcinomas varied from a soft pink mass to hemorrhagic, necrotic and sometimes caseous masses. Necrosis and hemorrhage were prominent in this group.

Metastases from carcinoma of the lung have been reported in practically every part of the body. Among sixty-seven cases in which the body was examined, Olson found somatic metastases in 92 per cent involving forty-five locations in the following order of frequency: the regional nodes, liver, adrenals, vertebrae, kidneys, retroperitoneal nodes, mesenteric nodes and

cervical nodes, opposite lung, mediastinal nodes and stomach. The undifferentiated small-cell type of tumor showed the most vigorous tendency to metastasize. In view of the relatively high incidence of lung cancer reported among the Schneeberg miners, it is interesting that in the Boston series pneumoconiosis was found in only 29 per cent of the cases. It appears that, in the general population, pneumoconiosis is not an important factor in the production of carcinoma of the lung.

PERPLEXING FEVERS

Immense progress in the understanding of fevers has been made since Galen divided fevers into three main groups: ephemeral, putrid and hectic.¹ While similar meaningless classifications of febrile disturbances appear throughout the writings of later medical men, the number and types of unexplained fevers have been enormously reduced by modern research. Pyrexia of unknown origin may be today the only available diagnosis in some obscure cases, but that cannot excuse its hasty adoption in any case.

Alt and Barker² investigated the subsequent histories and fate of 173 patients diagnosed over a period of years at the Peter Bent Brigham Hospital as having unexplained fevers. Of the 101 cases in which follow-up information was obtained, there were seventy-eight in which the cause of fever was never determined. In the majority of these, however, the fever was of less than ten days' duration. In twenty-three a pathologic condition that could account for the fever was later discovered. Tuberculosis, rheumatic infection, malignant disease and sepsis were encountered most frequently in this group.

In 1934 Kintner and Rowntree³ reported an analysis of 100 cases of long continued, low grade idiopathic fever. This group, like that of Alt and Barker, included more females than males. They believed that the basis for designating this type of fever as neurogenic or psychogenic was insufficient. Neurotic manifestations, however, were pronounced in at least 25 per cent of the cases. Focal infection was present in 35 per cent and its removal, though often individually helpful, did not much increase the percentage of recoveries. Ultimate discovery of the cause of fever in this group usually was conspicuously lacking.

Douthwaite⁴ recently suggested a broad classification of perplexing fevers. His first group is the endocrine in which the thyroid is the only member that at all frequently gives rise to slight but persistent pyrexia without obvious signs. In the fevers of toxic origin he includes degenerating new growths, cardiac infarctions, alcoholic hepatitis and certain drugs taken to reduce

3. Kintner, A. R., and Rowntree, L. G. Long Continued Low Grade Idiopathic Fever. *J. A. M. A.* 102: 889 (March 24) 1934.

4. Douthwaite, A. H. Pyrexia of Obscure Origin. *Lancet* 1: 1320 (June 8) 1935.

weight The third group comprises fevers of psychic origin He believes that the majority of these are fictitious, although some may be legitimate in nervous persons and especially in children As is well known, the tricks for the production of pyrexia by malingerers are legion Douthwaite's fourth group, the largest, includes the fevers of microbial origin, which agrees with the observations of Alt and Barker He places infective endocarditis, staphylococcic infections, food infections and tuberculosis especially high

Both Douthwaite⁴ and Wilson⁵ stress the importance of obtaining accurate and painstaking histories in attempting to detect the cause of obscure fevers The leukocyte count and a rectal examination may often lead to clarification Wilson adds the agglutination test for undulant fever and, on occasion, roentgen examination of the sinuses To these diagnostic procedures might be added the need for continued observation of those patients in whom all available measures fail to produce the diagnosis Greater care in the use of methods now available should lead to a further reduction in the percentage of fevers of unknown origin

Current Comment

ORAL IMMUNIZATION TO COLDS

For the last two winters, investigators have been studying the efficacy of an orally administered heterophile antigen vaccine in reducing the incidence of the common cold¹ The strains of common respiratory organisms used in the vaccine were selected for heterophile content and ability to resist the effects of gastrointestinal secretions The bacterial cultures were sterilized and the bacteria separated, absorbed on starch, dried and finally placed in capsules The organisms contained in each capsule were pneumococci, 25 billion, Hemophilus influenzae, 5 billion, streptococci, 15 billion, and Micrococcus catarrhalis, 5 billion The capsules were administered on an empty stomach daily during the first week and thereafter once or twice a week during the season The effectiveness seems to have been judged by the average number of colds occurring in the vaccinated group when compared with their average during the preceding three years and with "controls" not taking the vaccine In the winter of 1933-1934, 1,036 persons were included in the experiment, of which number 500 were given the vaccine In the succeeding winter 445 were given the vaccine and 469 others served as "controls" The statistics of the second year showed a decrease of 70 per cent in the average number of colds in the vaccinated group as compared with a decrease of 26.3 per cent in the "control" group Aside from the theoretical objections to oral vaccination for colds, many of which are obvious, there are some specific reasons against the acceptance of this

work as adequately controlled For example, the group taken as controls had, in all instances previous to the experiment, a lower average number of colds per season than the vaccinated group This factor alone does much to invalidate the control group Furthermore, in view of the known factors of age, exposure and tremendous variation in colds from season to season and in different locations, any yearly variation in cold morbidity in one location or in small groups is of small utility as scientific evidence The reports of the therapeutic value of orally administered "cold" vaccines are hardly convincing

DANGERS OF SLIMMING

Repeatedly and emphatically THE JOURNAL has published statements relative to extraordinary hazards involved in the sudden reduction of weight, occasionally described as banting, slimming, thinning, slenderization and in other ways From the time when dinitrophenol was first proposed as a product with specific favorable attributes for this purpose, THE JOURNAL warned against its uncontrolled use This was particularly the case because the product itself is not standardized and because there was hardly sufficient evidence available in the way of long continued study to say what the ultimate effects of the drug might be Now it appears that one of the ultimate and disastrous effects is in some persons rapidly developing cataracts Recently the occurrence of such cases was for the first time announced in THE JOURNAL² and in this issue several additional cases are reported Readers will remember records in relationship to the introduction of cinchophen, tetra-ethyl lead, carbon tetrachloride and carbon disulphide as well as many other products used in medicine and in industry in which only long continued observation permitted any final conclusion as to both the virtues and the hazards of the drug concerned Now comes evidence from many places that in certain instances the long continued use of dinitrophenol is followed by the development of cataract In occasional cases there are sensitizations which result in eruptions that may be dangerous to life and there are also records of granulocytopenia after taking this drug The Food and Drug Administration points out that dinitrophenol now forms the basis of a half dozen or more "patent medicines," including one called "Slim," which has been confiscated under the Food and Drugs Act, as well as others called Nitromet, Dimitrolac, Nitra-Phen, Dimitriso, Formula 281, Dimitrose, Nov Ben-01, Re-Du, Aldinol, Dimitronal, Prescription No 17, Dinitrole, Tabolin and Redusols In calling attention to these products Mr W G Campbell, chief of the Federal Food and Drug Administration, says "It is interesting to note that all the so-called reducing preparations on the market fall into three categories first, laxatives that deny the body the benefit of its food intake, as the salts, crystals and herb teas, second, obvious frauds that depend for effect upon the stringent diets prescribed as part of the 'treatment,' as

² Boardman W W Rapidly Developing Cataract After Dinitrophenol J A M A 105:108 (July 13) 1935 Horner W D Jones R B and Boardman W W Cataracts Following the Use of Dinitrophenol ibid p 108

'Syl-Vette' and 'Stardom's Hollywood Diet', and third, the unquestionably effective but dangerous articles containing thyroid or dinitrophenol, both of which act by speeding up the utilization of food. All of them are unwarranted impositions upon the public, which cannot evaluate claims made for the preparations and cannot readily appreciate the harm that may result from careless use of the products." His pronouncement is well warranted by the evidence available. For the benefit of the American people, it should be widely circulated through every means of dissemination of information to the public.

CALIFORNIA

Plague-Infected Ground Squirrels—According to *Public Health Reports* the director of public health of California reported positive findings for plague in thirty ground squirrels and four wood rats found in Modoc County and received at the laboratory May 8, June 1 and June 13 to 16. The squirrels were found on ranches near Alturas and the wood rats on a ranch near Likely. Eight ground squirrels from the Alturas vicinity received at the laboratory June 17 and one on the 21st were also found positive for plague.

COLORADO

Graduate Course in Ophthalmology and Otolaryngology—The thirteenth annual summer graduate course in ophthalmology and otolaryngology was held in Denver July 15-27, under the auspices of the Colorado ophthalmologic and otolaryngologic societies. Physicians giving lectures were:

Hans Barkan, San Francisco, Industrial Accidents;
John Milton Griscom, Philadelphia, External Diseases of the Eye;
Phillips Thygeson, Iowa City, Bacteriology of the Eye;
Edward Jackson, Denver, Causes and Management of Myopia, The Pupil in Vision;
William C. Bane, Denver, Photography of the Eye for Case Record Purposes;
Melville Black, Denver, Ocular Therapeutics;
Donald H. O'Rourke, Denver, Clinical Aspects of Glaucoma;
Ralph W. Danielson, Denver, Recent Advances in Illumination Relative to Visual Comfort and Acuity;
Samuel Iglauer, Cincinnati, Anatomy of the Neck;
Mervin C. Myerson, New York, Suppuration of the Petrona Pyramid;
Robert Levy, Denver, Laryngeal Tuberculosis;
Thomas E. Carmody, Denver, Malignancy of the Mouth and Face;
Frank R. Spencer, Boulder, Recent Advances in Otolaryngology;
George L. Patter, Denver, Diagnosis of Chronic Maxillary Sinusitis;
Herman I. Laff, Denver, Pathologic Demonstration Cases of Post-auricular Sinusitis;
Harold L. Hickey, Denver, Management of Otic Blood Stream Infections;
Cecil H. Darrow, Denver, Practical Considerations in Peroral Endoscopy;
Harry L. Baum, Denver, Specific Convalescent Serum Treatment in Otolaryngology.

GEORGIA

Annual Registration of Licentiatees of State Examining Boards—The joint secretary, state examining boards, will mail about September 1, to all licentiatees of the state board of medical examiners and of other Georgia state examining boards blanks to enable them to comply with the law requiring annual registration. No fees attach to such registration. Physicians will do well to execute the blanks furnished and to return them to the joint secretary as promptly as possible.

Tuberculosis Work Increasing in State—More accomplishments were noted in tuberculosis control in the first six months of 1935 than for any other similar period, owing largely it was stated, to the service rendered by the ten tuberculosis nurses furnished by the Federal Emergency Relief Administration. During this period these nurses made visits to 7,432 families and visited 2,436 cases of tuberculosis making a total of 16,766 visits to suspected cases, contacts cases and other persons. In addition to the work done by the nurses, 3,249 tuberculin tests were made by county health commissioners and public health nurses who organized nineteen clinics

and had 1,534 roentgen examinations made by the x-ray unit of the state department of public health. There were 109 clinics held to serve 115 counties, and 7,567 roentgen examinations were made. Of this number, 562 persons were found to have tuberculosis, 389 of whom were white and 173 colored. It was pointed out that of the 100 new cases brought to notice each month through the tuberculosis control division of the state department, at least 90 per cent need treatment, medical supervision and social service to some degree for a long indefinite period. The disease now holds sixth place among all causes of death in the state. The death rate was 58.9 per hundred thousand of population in 1934, 73.7 in 1931 and 78.5 in 1926.

ILLINOIS

Urge Discontinuance of Shipment of Dogs' Heads by Mail—The illegal practice of shipping mad dog heads to state diagnostic laboratories in Springfield has grown to such proportions that Dr. Frank Jirka, state health officer, has appealed to the postoffice department in Washington for assistance in discouraging the use of the postal service for this purpose. It was pointed out that it is illegal, hazardous and nearly always worthless to ship dogs' heads by mail to the laboratories for examination for rabies, furthermore, since the heads are not in sealed metal containers, they expose postal employees to infection, not being packed in ice they decompose en route, making it difficult if not impossible for laboratory technicians to determine whether or not the dog was rabid. To date this year 559 heads have been examined, the largest number in several years, while about 1,435 persons have received antirabic treatment.

INDIANA

Society News—At a meeting of the Vanderburgh County Medical Society, June 25, a resolution was adopted favoring the appointment of a full time health officer for Evansville and Vanderburgh County.—Dr. Carl D. Camp, Ann Arbor, Mich. discussed "Disturbances of Sleep, Insomnia and Hypersomnia" before the Tippecanoe County Medical Society, September 10.

Memorial to Physician—A portrait of Dr. William J. Bauer with a bronze memorial tablet, was presented by the Medical Staff Society to the Methodist Hospital, Indianapolis, June 30. It will hang in the resident physicians' office. Dr. Bauer, who died in February during his term as chief resident physician, established the resident physician and intern service in the institution as it now is, according to the Indianapolis Medical Society Bulletin. He graduated in 1933 from the State University of Iowa College of Medicine, Iowa City. About 100 physicians attended the ceremony, during which Drs. Edmund D. Clark and John M. Whitehead unveiled the portrait, and John G. Benson, D.D., superintendent, and Dr. Clark paid tribute to Dr. Bauer.

KANSAS

Annual Registration Now Due—Physicians licensed to practice medicine in Kansas are required to renew their licenses annually, between July 1 and October 1, and to pay a fee of \$1 to the secretary of the board of medical registration and examination. The secretary must strike from the register of licensed physicians the names of all physicians who fail to pay their annual registration fees as required by law. Physicians whose names are so removed may be reinstated by paying the secretary \$5 and submitting to him satisfactory proof of moral fitness.

MARYLAND

Dr. Hughson Leaves Johns Hopkins—Dr. Walter Hughson, associate professor of otology at Johns Hopkins University School of Medicine, Baltimore, has resigned to become director of a new otologic research laboratory at the Abington Memorial Hospital, Abington Pa., near Philadelphia. The new laboratory, which is said to be specially designed for Dr. Hughson, was made possible by a special fund for otologic research at the hospital. Dr. Hughson, who has been teaching at Johns Hopkins since 1920 graduated from the institution in 1918. He will take over his new position in September.

Expedition to South Seas—Dr. Francis D. Coman, Baltimore, who was medical director of the first Byrd Expedition to the antarctic, chartered a two masted schooner, the *Kuikajon*, and sailed, July 15, on an expedition to the South Seas. He will gather meteorological and other data for a projected commercial airline to the antipodes. Dr. Coman is on leave from his position as assistant in psychiatry at Johns Hopkins Uni-

versity School of Medicine. A graduate of Johns Hopkins, Dr Coman has been associated with it since his graduation in 1924. He was medical director of the Byrd expedition from 1928 to 1930 and received the Congressional Medal for his services on that trip.

New Baltimore General Hospital—The new building for the general division of the Baltimore City Hospitals was dedicated recently with former Governor Albert C. Ritchie presiding. Accommodating 400 patients, the unit is part of a construction program begun at the Baltimore City Hospitals in 1927. This program is financed by a loan of \$4,000,000 approved in that year by the state legislature. New units include the nurses' home, which has accommodations for 253 nurses, an addition for chronic patients now under construction, which will care for 240 additional patients, an addition to the tuberculosis building now being erected to care for 134 additional patients, and a power plant. When all the units now under construction are completed and the contemplated changes are made, 2,800 beds will be available, of this number 1,700 will be patients and 1,100 indigent old persons. This number will be reduced by 300 over the next three years as the state gradually takes over the institution's insane patients, in accordance with a plan already worked out. The speakers at the dedicatory ceremony included Dr Thomas R. Boggs, physician in chief of the Baltimore City Hospitals, who sketched the history of the institution from its inception in 1776 to its present place in the community. The Baltimore City Hospitals, founded in 1865, had its beginning in the old "poorhouse" for care of the indigent. From year to year since that time its other services have been added.

MICHIGAN

State Medical Meeting—The Michigan State Medical Society will hold its annual meeting at Sault Ste Marie, September 23-26, under the presidency of Dr Richard R. Smith, Grand Rapids. The house of delegates will meet Monday afternoon and Tuesday morning. The scientific program will be presented by the following physicians:

Jennings C. Litzberg, Minneapolis. Maternal Mortality.
John H. Musser, New Orleans. Medical Aspect of Gallbladder Disease.
George W. Hall, Chicago. Relation Between Physical and Psychic Disturbances.
Frederick A. Collier, Ann Arbor. Surgical Aspect of Gallbladder Disease.
Harry L. Huber, Chicago. Allergy and the General Practitioner.
Walter G. Maddock, Ann Arbor. Diseases of Peripheral Arteries—Their Interference with Normal Physiology and Evaluation of Newer Methods of Treatment.
Martin A. Mortensen, Battle Creek. Hypoglycemia in the Vagotonic.
William H. Gordon, Detroit. Compensatory Hypertrophy and Hyperplasia of Islands of Langerhans in Utero. Congenital Hypoglycemia Due to Hyperinsulinism.
Lester M. Wieder, Milwaukee. Common Fungus Dermatoses.
Clyde Emerson Vreeland, Detroit. Achlorhydria—Its Clinical Significance and Management.
Norman F. Miller, Ann Arbor. Common Lesions of the Cervix.
Erwin R. Schmidt, Madison, Wis. Postoperative Oxygen Therapy.

Dr Smith will deliver his presidential address Wednesday evening, and Dr Solon Marx White, professor of medicine, University of Minnesota Medical School, Minneapolis, will present the first Andrew P. Biddle Oration, entitled "The Status of the Hypertension Problem." Arrangements are being made for physicians in the southern part of Michigan to attend the meeting on a special boat cruise.

MINNESOTA

Contaminated Wells Closed—The survey of the water systems of Minneapolis and St Paul that followed the outbreak of typhoid involving more than 100 cases, has resulted in the closing of twenty-four contaminated wells in various parts of Minneapolis, newspapers stated.

MISSISSIPPI

Personal—Dr George F. Carroll has been assigned as chief of surgical service at the Veterans Administration Facility in Biloxi.

Society News—The Northeast Mississippi Thirteen Counties Medical Society was addressed in Houston, June 18, by Drs James B. McElroy, Memphis, on heart diseases, Frank L. McGahey, Calhoun City, toxemias of pregnancy, John G. Lilly Jr., Tupelo, transfusions, and Laurence B. Morris, Macon, empyema. Dr Jesse T. Davis, Corinth, reported a case of Madelung's deformity. —Dr Thomas D. Moore, Memphis, discussed the "Conservative Treatment of Surgical Lesions of the Kidney," July 17, before the quarterly meeting of the North Mississippi Medical Society in Holly Springs and Dr Edward C. Mitchell, Memphis, spoke on diarrhea.

NEBRASKA

Annual Registration Now Due—Physicians licensed to practice medicine in Nebraska are required by law to register with the department of public welfare annually, on or before October 1, and to pay a fee of \$1. A license expires if the licensee fails to register, but within the thirty days next following its expiration it may be revived by the payment of the registration fee and a penalty of \$1. If that is not done, an order of revocation is issued and thereafter the revoked license can be reinstated only on the recommendation of the board of examiners in medicine and on the payment of the renewal fees and penalty then due.

Annual Clinical Meeting—The Omaha Mid-West Clinical Society will hold its third annual meeting at the Hotel Paxton, Omaha, October 28-November 1. Guest speakers include the following physicians:

Joseph Brennemann, Chicago. Pediatrics.
William B. Carrell, Dallas, Texas. Orthopedic surgery.
Arthur B. Cecil, Los Angeles. Genito-urinary.
Russell L. Cecil, New York. Medicine.
Arthur C. Christie, Washington, D. C., radiology.
Vernon C. David, Chicago. Surgery.
James R. Goodall, Montreal, Que., gynecology and obstetrics.
Roy R. Grinker, Chicago. Neurology.
Andrew C. Ivy, Chicago. Clinical physiology.
Jay Arthur Myers, Minneapolis. Tuberculosis.
Edward C. Sewall, San Francisco. Eye, ear, nose and throat.
Udo J. Wile, Ann Arbor. Dermatology.

NEVADA

Personal—Dr George R. Smith has resigned as superintendent of the Nevada Hospital for Mental Diseases, Reno, and Dr James C. Ferrell, Fallon, has been appointed to succeed him.

NEW JERSEY

Personal—Dr Jesse Lynn Mahaffey, Haddonfield, was reelected director of the state department of health for a term of four years. Dr Irvin E. Deibert, Camden, was elected president of the state board of health.

Joint Meeting—The Bergen County Medical Society and the Bergen County Pharmaceutical Association will hold a joint session at the Englewood Hospital, September 10. Lloyd K. Riggs, Ph.D., director of research and professor of physiology, New Jersey College of Pharmacy, Rutgers, will discuss "Evaluation of Antiseptics in Modern Practice," and Dr Albert F. R. Andresen, clinical professor of medicine, Long Island College of Medicine, Brooklyn, "Focal Infection."

NEW MEXICO

British Physicians Visit Indian Village—Members of the British Medical Association, on their way to Australia to attend the association's annual meeting in September, were greeted in Albuquerque, August 10, by the Bernalillo County Medical Society and taken by motor to Isleta Pueblo, one of the largest Indian villages in the state. In this pueblo is one of the famous old mission churches erected about 1621, which is considered the seat of the earliest attempt by white men to educate the Indian. After a visit to the pueblo the guests were entertained at a tea before their departure.

NEW YORK

Precipitated Toxoid Ready for Distribution—Precipitated diphtheria toxoid is now available for general distribution through district supply stations, the state department of health announces. The toxoid will be distributed in small packages for the convenience of physicians and in larger ones for use in clinics and institutions.

New York City

Epidemic May Delay Opening of Schools—If the outbreak of infantile paralysis in the city continues to increase, the opening of schools may be postponed, it was reported, August 28. With sixty-three new cases reported on this date, the year's total stood at 1,007 cases, with forty-two deaths.

Health Needs of Vagrants—The New York Emergency Relief Bureau made a health study of 505 persons arrested for vagrancy in the police drive to halt crime in the parks. Of this number 116 were hospitalized, forty-seven for social diseases and fourteen for acute infections. One case of epilepsy was found, one case of tuberculosis and one psychopathic case. Many of the men were found to be in various stages of alcoholism. According to the New York Times, the study was carried on for one week in August as a part of the mendicancy project of the relief bureau.

Eighth Graduate Fortnight—The New York Academy of Medicine will present its eighth annual graduate fortnight, October 21 to November 2, on the general subject "Diseases

of the Respiratory Tract" Eighteen hospitals will present clinics and clinical demonstrations in the afternoons, and evenings will be given over to formal meetings at the academy. Speakers at the evening sessions will be

Landell Henderson Ph.D. New Haven Conn. Atelectasis, Massive Collapse and Related Postoperative Conditions (the Wesley M. Carpenter Lecture)
Dr. Maximilian A. Ramirez New York, Allergy in Its Relationship to Diseases of the Respiratory Tract
Dr. Jonathan C. Meakins Montreal Chronic Pneumonitis
Dr. Charles Hendee Smith New York The Pneumonias of Children.
Dr. Charles T. Porter Boston Sinus Disease from Infancy to Old Age
Dr. Charles J. Imperatori New York Diseases of the Larynx Trachea and Main Bronchi
Dr. Harrison S. Martland Newark N. J., Diseases of the Mediastinum.
Dr. Lloyd F. Craver New York, Tumors of the Lung
Dr. Leroy U. Gardner Saranac Lake N. Y., Pneumoconiosis
Dr. James Burns Amberson Jr. New York, Bronchiectasis Types
Diagnosis Prevention and Treatment
Dr. Arnold R. Rich Baltimore, Immunity in Tuberculosis
Dr. James Alexander Miller New York Evolution of Pulmonary Tuberculosis
Dr. Chevalier L. Jackson Philadelphia Bronchoscopy in Its Relation to Diseases of the Respiratory Tract
Dr. David Riesman Philadelphia Emphysema
Dr. George Blumer New Haven Thrombosis and Embolism.
Dr. Harry Wessler New York Abscess and Gangrene
Dr. Alphonse R. Dochez New York, The Common Cold.
Dr. Henry T. Chickering New York Influenza of the Respiratory Tract.
Dr. Adrian V. S. Lambert New York Surgery of Tuberculosis of the Chest
Dr. Howard Lilienthal New York Chronic and Subacute Empyema.

A comprehensive exhibit with demonstrations at regular intervals will also be part of the program

NORTH CAROLINA

Personal—Dr. Clarence H. White, Kenansville, has been made district health officer, with jurisdiction over the health boards of Avery, Yancey and Watauga counties.—Dr. Alfred D. Gregg, Liberty, has been appointed health officer of Edgecombe County to succeed Dr. Rembert E. Broadway, Tarboro, who resigned to engage in private practice. Dr. George H. Sumner, Asheboro, has been appointed health officer of Randolph County to succeed Dr. Gregg

OHIO

Meeting at Marion.—At a meeting of the Northwestern Ohio Medical Association, September 24, in Marion, speakers will be

Dr. Henry H. Ritter, New York, Ambulatory Treatment of Fractures
Dr. Harold Feil Cleveland Changing Trends in Heart Disease.
Dr. Rupert Franklin Carter New York Appendicitis in Children.
Dr. William H. Gordon Detroit Malignant Neutropenia
Dr. Henry Schmitz Chicago Cancer

At a public meeting in the evening, Dr. Morris Fishbein, Chicago, Editor of THE JOURNAL, will give an address on "Medicine in the Changing Social World."

OKLAHOMA

Personal—Dr. Dock Long, Duncan, has been appointed health superintendent of Stephens County, and Dr. James E. Jones, Hollis, of Harmon County.—Dr. Perry J. Cunningham, Afton, has been named physician of Ottawa County, he will reside in Miami after September 1.—Dr. George N. Bilby, former state health commissioner, has reentered the practice of medicine at Alva.

Committee to Standardize Institutions for Crippled Children—A standardization committee has been appointed and a state commission for crippled children created under a law that went into effect July 1. The standardization committee, composed of Drs. Maurice J. Searle, Tulsa, Earl D. McBride, Oklahoma City, William P. Fite, Muskogee, John F. Park, McAlester, and Walter M. Browning, Waurika, will pass on hospitals and convalescent homes in the state qualified to care for crippled children. The commission for crippled children will consist of the state superintendent of health as chairman, the dean of the medical school and the state superintendent of public instruction, and will probably be designated to handle the federal grant for crippled children. The hospitals of the state have been divided into four classes according to the type of case handled: crippled children's hospital, general hospital, standard hospital and convalescent homes. To be approved each institution must conform with certain standards. The amended crippled children's law now provides for medical and surgical treatment and hospital and convalescent care for children who are afflicted with any malady or deformity that can be remedied, whose parents are unable to provide it for them. Formerly this care was provided for in state institutions but now the state will pay for this care in any institution approved by the committee on standardization.

OREGON

State Medical Meeting at Gearhart, September 19-21—The sixty-first annual session of the Oregon State Medical Society will be held at the Hotel Gearhart, Gearhart, September 19-21. Out-of-state speakers will include Drs. Hubbard T. Buckner, Seattle, "Treatment of Supracondylar Fractures of the Elbow," and Hans Lisser, San Francisco, "Pituitary-Adrenal Relationships." In addition to a symposium on common errors responsible for maternal mortality by Drs. Raymond E. Watkins, Virgil E. Dudman, Goodrich C. Schaeffer and Theodore W. Adams, all of Portland, the following physicians will speak

Paul H. Nitschke Portland Causes and Treatment of Urinary Retention
Thomas D. Robertson Portland An Analysis of Fatal Thrombotic Pulmonary Embolism
Roy C. McDaniel Portland Eradication of Hernia by Injection
George W. Millett, Portland, Significance of Gastro-Intestinal Hemorrhage
Lorenzo D. Inskeep Medford, Etiologic Factors in So-Called Idiopathic Epilepsy
Millard S. Rosenblatt Portland Goster Interesting Practical Points
Arthur C. Jones Portland Diathermy and Short Wave Radiotherapy
Otis B. Wight Portland Plans of the State Cancer Committee and Fundamentals of Cancer
James C. Hayes Medford, Torsion of the Testis
Banner R. Brooke, Portland Phases of Rectal Pathology
James Marr Bissillon Portland Differential Diagnosis of Thoracic Disease
Eugene W. Rocky Portland, Problems of the Physician and the State Industrial Accident Commission
Samuel G. Henricke, Portland Preventive Medicine in Private Practice.

Dr. Lisser will also give a lantern slide clinic on endocrine disorders. The annual banquet will be Friday evening, when the presidential address will be given, and the ninth annual golf tournament will be held Saturday afternoon. The prizes will be awarded at a dinner that evening.

PENNSYLVANIA

County Society Operates Contagious Disease Hospital—The Municipal Isolation Hospital of Johnstown, a new seventy-five bed institution owned by the city and operated by the Cambria County Medical Society, was dedicated June 14. This hospital was founded in 1902 in a tent. The next year a rough building was erected as an isolation camp during an epidemic of smallpox. A few years later convalescent patients partly finished the interior and the building remained in that condition until 1928, when the county medical society took it over, with Dr. Henry W. Salus as director. It has now a staff of fourteen physicians. After several years' efforts, funds were acquired for the new building, which was begun in November 1934. It is a one-story structure of cut stone and covers a fourth of a city block. At the dedication in June a bronze tablet was presented to Dr. Salus by the directors and the staff in recognition of his work in building up the hospital.

Isolation Hospital

TENNESSEE

Personal—Dr. Edward A. Guynes has been named chief of staff of the Knoxville General Hospital to succeed Dr. Andrew Smith, who was recently made superintendent of the hospital.—Dr. Perry Priest has resigned as medical superintendent of the Tennessee Home and Training School for Feebleminded Persons at Donelson, and Dr. Oscar S. Hawk of the staff of the Central State Hospital at Nashville has been appointed to succeed him.—Dr. Hilton R. Carr, Memphis has resigned as superintendent of the Shelby County Hospital to enter private practice.—Dr. Bernard W. Patton, Lebanon, was recently made health officer of Wilson County to succeed Dr. William D. Cagle.

Society News—At a meeting of the Hardin, Lawrence, Lewis Perry and Wayne County Medical Society, July 30, Drs. Joseph P. Gilbert discussed mental disease, Milton Smith Lewis Nashville, diagnosis and management of the occipito-posterior position, and Eli H. Etheridge, Loretto, diagnosis of cancer of the lungs.—The Washington County Medical Society was addressed in Johnson City, July 11, by Drs. Cassius W. Friberg on toxemias of pregnancy, and Lee K. Gibson, appendicitis.—The Black Patch Medical Society was

addressed by Drs Murray B Davis and William H Witt, Nashville, on treatment of burns and symptoms of diseases, respectively

WEST VIRGINIA

Dr Simpson Retires as Dean—Dr John N Simpson, dean of the medical faculty of West Virginia University School of Medicine since he organized it in 1902, has retired with the title of dean emeritus, and Dr Edward J Van Lue, since 1922 professor and head of the department of physiology, has been named acting dean. Dr Simpson is 66 years of age. He was professor of physiology at the school from 1902 to 1920, since which time he has been professor of medicine, and director of the hygiene laboratory of the state department of health from 1913 to 1917. He graduated from the Johns Hopkins University School of Medicine in 1902. The West Virginia University School of Medicine, which offers only the first two years of the medical course, is now being reorganized (THE JOURNAL, August 24, p 606)

WISCONSIN

Bequest for Cancer Therapy—Columbia Hospital, Milwaukee, has received a bequest of \$7,000 from the estate of the late Mrs Sarah A Spalding to finance a new department for treatment of cancer by high voltage roentgen therapy. Two rooms have been set aside for the new department, in which a high voltage x-ray machine is to be installed. Dr Silvanus A Morton will be in charge.

Cancer Clinics—Six clinics on cancer were conducted in different parts of the state of Wisconsin, July 8-13, under the auspices of the Wisconsin State Medical Society, the University of Wisconsin Medical School and the American Society for the Control of Cancer. The clinics were held by Drs Ellis Fischel, St Louis, William P Healy, New York, and Frank L Rector, Evanston, Ill., to demonstrate new methods of diagnosis and to present to the general practitioner the latest data on prevention and cure of cancer. A public lecture was given after each clinic.

Society News—Drs William E. Bannan and James A. Evans, La Crosse, addressed the Barron-Sawyer-Washburn Counties Medical Society, Rice Lake, June 4 on "Urologic Pathology in General Practice" and "Heart Failure and Treatment," respectively. Dr Owen C Clark, Oconomowoc, addressed the Waukesha County Medical Society, Waukesha, June 5, on agranulocytosis. The Fifth District Medical Society held its annual meeting at Sheboygan, July 11, with the following speakers: Drs Samuel F Haines, Rochester, Minn., "Medical Aspects of Thyroid Disease", Elmer L. Sevringhaus, Madison, "Diagnostic and Therapeutic Problems of the Menopause", Arlie R Barnes, Rochester, "Coronary Sclerosis", and Ralph M Carter, Green Bay, "Orthopedic Conditions of Interest to the General Practitioner". Dr Gilbert E. Seaman, superintendent, Northern Hospital for the Insane, Winnebago, made an address at a banquet in the evening on "Problems in the Care of the Mentally Ill".

GENERAL

Medical Facilities on the Normandie—Two hospital units of thirty-five beds each for passengers and crew are a part of the equipment of the new French liner *Normandie*. Dr Joseph Bohec, Paris, is ship surgeon, assisted by two physicians and seven nurses. The medical equipment includes physical therapy apparatus, a radiology room and an apothecary shop. There is also a fully equipped medical and surgical clinic.

Examination in Obstetrics and Gynecology—The American Board of Obstetrics and Gynecology announces that the next written examination and review of case histories of group B applicants for certification will be held in various cities in the United States and Canada, December 7. Application blanks and further information may be obtained from Dr Paul Titus, secretary of the board, 1015 Highland Building, Pittsburgh (6), Pa. Applications must be filed not later than November 1.

Prevalence of Infantile Paralysis—Seventeen new cases of infantile paralysis reported in Virginia, August 19, according to the newspapers, brought the total in the state since the first of the month to 202. Twenty-two new cases, August 27, brought the total in Massachusetts for the month to 408. Fifty-nine cases were reported to the New Jersey Department of Health between July 1 and August 21. As a precautionary measure in Grand Rapids, Mich., wading pools have been closed and children up to 11 years of age have been barred from swimming pools in the city. The health officer of Bay City, Mich., and the Bay County Medical Association have jointly

asked for the donation of blood by persons who have recovered from the disease, the contributions to be used for serum treatment of active cases. Playgrounds and theaters in Wyandotte were ordered closed to children under 17, and three boys' camps in the state have been closed. In Louisville, Ky., there have been thirty-eight cases, with two deaths.

Tuberculosis Mortality Lower—A study of the tuberculosis death rate in forty-six large cities in 1934, recently issued by the New York Tuberculosis and Health Association, indicates that the rate for the whole group is 4 per cent lower than the 1933 rate, 69.6 per hundred thousand as compared with 72.5. Sixteen cities showed increases, however, as follows: Denver 3 per cent, Cleveland 3, Buffalo 3, Minneapolis 8, Cincinnati 2, Indianapolis 3, Houston 6, Rochester, N Y., 18, Columbus 15, Oakland, Calif., 12, Atlanta 16, Akron 3, Syracuse 3, Omaha 39, Paterson 7, Elizabeth 21. New York, Chicago, Detroit and Los Angeles showed decreases, and Philadelphia's rate did not change. Dallas showed the greatest decrease, 25 per cent. Akron, Ohio, had the lowest rate, 35, and San Antonio the highest, 145. A separate compilation of Negro deaths showed a rate of 220.9 per hundred thousand among Negroes, a reduction of 5 per cent from 1933. The white death rate was 56. These figures include deaths of residents out of town whenever they were known.

Life Expectation in Rural Areas Greater—Figures relating to the white population of the United States for 1930 recently made available by the Metropolitan Life Insurance Company, reveal that the rural dweller has, on an average, four or five years longer life than the urban resident. At birth, a white male has an expectation of life of 56.73 years if an urban resident and of 62.09 years if dwelling in a rural section. The corresponding figures for a white woman are 61.05 and 65.09. The figures cited are not adjusted for deaths of rural inhabitants who die in city hospitals but, broadly speaking, they are characteristic of urban and of rural longevity. The states with especially high expectation of life are typically agricultural, while the typically industrial states are below average or only a little above. New Mexico and Arizona show a very low expectation of life in spite of a low degree of industrialization, however, these states have a high percentage of Mexican population whose mortality is markedly above that of other persons together with whom they have been classified as white.

Control of Compounds of Codeine—A recommendation that exemption from the import certificate system be allowed to solid compounds containing codeine and ethylmorphine hydrochloride (dionin) only when these drugs are associated with other medicinal substances was brought in by a special subcommittee at the twentieth session of the Advisory Committee on Traffic in Opium and Other Dangerous Drugs of the League of Nations, at Geneva, Switzerland, May 20-June 5. It was also recommended that exemption should not be allowed to liquid compounds consisting of codeine or ethylmorphine hydrochloride in one or more inert fluids. The Opium Advisory Committee at this session recognized that the menace of cannabis is increasing in many countries. Plans were made to build up a library on cannabis in the League of Nations and to develop chemical tests to show the presence of cannabis derivatives by processes suitable for use by police officers. Dr Walter L Treadway of the U S Public Health Service was appointed to a committee to study the effects of the abuse of cannabis and methods to cure addiction. The views of the United States that dried poppy heads and poppy straw are to be classified as raw material and subject to national and international control were also accepted by the committee.

LATIN AMERICA

Pan-American Congress on the Child—The seventh Pan American Congress on the Child will be held in Mexico City, October 12-19, under the auspices of the department of public health. Dr Abraham Ayala Gonzalez, chief of the health department is president of the organizing committee, and Dr Alfonso Pruneda general secretary. There will be the following seven sections of the congress: pediatric medicine, pediatric surgery and orthopedics, child hygiene, social service, legislation and education. Subjects to be treated in the medical section include rickets, allergic states in children and mucohemorrhagic colitis in the surgical and orthopedic section, focal infections, paralysis in children and tuberculous osteoarthritis.

CORRECTION

Diagnosis of Congenital Syphilis—At the end of the article by Drs A H Parmelee and L J Halpern in THE JOURNAL, August 24, page 563, the address of Dr Halpern should be 6355 Broadway at Devon.

Foreign Letters

LONDON

(From Our Regular Correspondent)

Aug 10, 1935

The Second International Neurological Congress

The second International Neurological Congress was held in London from July 29 to August 2. It was attended by 677 members from forty-two countries (almost all the civilized countries of the world), about sixty members coming from the United States. The chief officials were Dr Gordon Holmes, F.R.S., president, Dr S. A. Kummer Wilson, secretary general, Dr Macdonald Critchley and Dr E. A. Carmichael assistant secretaries, Dr Anthony Feiling, treasurer, Dr Bernard Sachs and Sir C. S. Sherrington, honorary presidents. The congress met in seven sections for which ample accommodation was provided at University College, and nearly 300 papers were presented. The arrangements were excellent except that the time limit for papers was not always observed, with the result that some papers were crowded out. The mornings were devoted to discussions on selected subjects, which began with a series of papers and then became open. These subjects were "The Epilepsies," "The Physiology and Pathology of the Cerebrospinal Fluid," "The Functions of the Frontal Lobes" and "The Hypothalamus and the Central Representation of the Autonomic System." The afternoons were devoted to miscellaneous papers, which were grouped as follows into the various sessions: Clinical Neurology, Pathology, Physiology, Anatomy, Physiology of the Autonomic System, Clinical Physiology, Intracranial Tumors, Pathology of the Cerebrospinal Fluid, Psychopathology, Diagnostic Methods and Surgical Diseases, Experimental Neurology and Treatment. The member of the congress who attracted most attention was Professor Pavlov. Though an octogenarian, he is still alert. When he got up to speak as well as when he sat down he received an ovation.

THE MOTOR CORTEX IN THE LIGHT OF HUGHLINGS JACKSON'S DOCTRINES

The congress attended a special meeting of the Neurological Section of the Royal Society to hear the lecture in commemoration of the centenary of the birth of Hughlings Jackson, which was delivered by Prof. Otfried Foerster of Breslau. The congress medal bore the effigy of Hughlings Jackson. Professor Foerster said that Jackson was the first to point out the existence of the motor cortex, which he inferred from the experiments performed on the brain by disease before physiologists confirmed his view. The motor functions of the cortex were then unknown and epilepsy was believed to be a manifestation of disorder of the pons and the medulla. Jackson relied on his incomparable power of deductive reasoning. He recognized that epileptic convulsions were a caricature of normal movements and announced the then revolutionary view that the cortical motor cells must be concerned. He believed that no part of the cerebral hemispheres was purely motor or purely sensory and so it has proved, for Professor Foerster by electrical stimulation of the human cortex has shown that, from areas other than the precentral complex movement and postures can be elicited. Foerster believes that these extrapyramidal motor centers are the source of the relatively cumbersome movements possible in the hemiplegic patient after damage of the pyramidal tract. There was scarcely a neurologic problem that had not been illuminated by Hughlings Jackson's ingenuity. Dr Sittig of Prague pointed out that Jackson had anticipated Freud in his view of the unconscious, a fact that has previously been unnoticed. Jackson held that when in disease insanity or

dreams the highest cerebral level was put out of function the next lower level became more active. The positive symptoms of insanity thus came out of the unconscious.

PAIN RESULTING FROM PRODUCTS OF METABOLISM OR TISSUE DAMAGE

Sir Thomas Lewis said that because simple physical interferences are apparently capable of stimulating nerves directly there has been a tendency to interpret most pains as a result of physical changes induced in nerve endings directly. This may be true in many instances, but other methods of stimulation are becoming apparent. Evidence has been accumulating which suggests that malnutrition or injury of tissues may so change the local chemical or physicochemical environment of nerve endings as to stimulate them. Thus it seems established that the products of the work of somatic muscle may accumulate in the tissue spaces until they start pain impulses. In the case of injuries to the skin there is definite evidence that substances released from the skin act thus. The idea that sensory nerve endings may be stimulated by natural chemical or physicochemical tissue changes has been taken beyond the stage of theory by the pain produced by the arrest of blood flow to a part.

THE EFFECT OF REMOVAL OF BOTH FRONTAL LOBES

Dr R. M. Brickner of New York described a unique case in which both frontal lobes were removed for meningioma. Broca's area and the motor cortex were left intact. In all, 116 Gm of brain tissue was removed. As the amount of damage done to the brain was known with fair exactness, the function of the missing parts in this patient, a man of 44, could be deduced. The changes were of two kinds: (1) intellectual defects, such as impairment of memory, (2) impairment of control over emotional drives, perhaps because he had lost knowledge of the social gain from such control. He became like a child who had not yet learned to adapt himself to the people he must meet in the world. The whole effect might be interpreted as loss of the elaborate association or synthesis into complex structures of the simpler engrammatic products associated in the more posterior parts of the brain. It might be described as loss of ingenuity. The indication is that man needs a frontal lobe which can ingeniously comprehend the emotions well enough to control them instead of yielding to them.

THE PATHOGENESIS OF EPILEPSY

Dr W. G. Lennox of Boston had found that certain alterations of physiologic processes of the brains of epileptic patients modified the frequency of the seizures. 1. Acid base equilibrium. Alkalosis by overventilation or by ingestion of alkali tended to increase seizures, acidosis induced by fasting, a ketogenic diet, ingestion of acids, breathing carbon dioxide or muscular activity tended to decrease seizures. 2. Cerebral blood flow. The total blood flow through the brain, measured by a thermo-electric recorder, does not show reduction before the seizure except when this is induced by overventilation. Hence general cerebral anemia is not the cause of the seizures. 3. Oxygen. The volume of oxygen consumed between seizures is normal or moderately reduced. Immediately before and during nonconvulsive seizures there is no significant alteration in oxygen consumption. Induction of cerebral anoxemia (by breathing pure nitrogen or ingestion of sodium nitrite) produced an attack in only one out of twenty cases of grand mal, but in petit mal a seizure was constantly produced. 4. Electrical activity of the brain. Petit mal seizures were found to be invariably preceded or accompanied by a burst of electrical potentials about ten times the voltage and about one-fifth the frequency of the patient's usual potentials. Clonic movements were synchronous with these large waves, similar voluntary movements were unattended by differences in electrical potential. The conclusion was that abnormal physiologic states, such as

alkalosis, cerebral anemia or anoxemia, are not the usual causes of seizures but that they may alter the seizure threshold and precipitate seizures in petit mal

THE SURGICAL TREATMENT OF HYPERTENSION

Dr Max M. Peet described sixty cases in which operation for hypertension had been performed at University Hospital, Ann Arbor, Mich. He resected the greater and lesser splanchnics and the lower dorsal sympathetic chain (tenth to twelfth ganglions). The operation was done above the diaphragm after resecting the eleventh rib. The blood pressure in all cases was at some time over 200 and it ranged from 210 to 300. Many of the patients had retinal hemorrhages, masses of exudate and papilledema. Severe kidney damage in the absence of high nonprotein nitrogen was not considered a contraindication to operation. Improvement was obtained in 85 per cent, varying from simple relief of headaches to apparently complete cures. Ten per cent were not benefited and about 15 per cent were apparently cured. In some of the latter a blood pressure as high as 285 was reduced to 130-140 over periods ranging from six to seventeen months. A complete return to normal vision and normal kidney function took place.

Bone-Muscle Syndrome Improved After Parathyroidectomy

Richet and his associates reported a case presenting a curious syndrome at the April 12 meeting of the Société médicale des hôpitaux. A man, aged 27, complained of impotence and complete rigidity of the lower extremities, trunk and neck of seven years' duration. Active and passive efforts to move the affected muscles were impossible owing to the pain during such movements. There was a complete ankylosis of both hips. The muscles, especially of the thighs, felt very hard, having almost the consistency of a board. There was a well marked Chvostek sign, and tic movements of the facial muscles frequently occurred. The tendon reflexes were normal. There was a similar history in the mother of the patient. The blood examination of the latter revealed at times a marked calcium retention, while at other examinations the calcium content of the blood showed a hypocalcemia. All efforts in the form of a diet, low in calcium but rich in acid content, as well as the daily injection of parathyroid extract were of no avail. Biopsy of the muscular tissues revealed an advanced sclerosing myositis. Removal of one of the parathyroids was decided on. The gland was very large, and histologic examination revealed a marked adenomatous change. This operation was followed by disappearance of the pain on movement and of the board-like rigidity of the muscles. The hypercalcemia disappeared and roentgenography revealed a recession of the periosteal proliferations. The patient for the first time in two years is now able to get out of bed and walk. In the opinion of Richet and his associates, the case represents a dysfunction of the parathyroids resulting in an osteoarthritis and a sclerosing myositis.

Innocuity of BCG Vaccine

Negre and Valtis of the Pasteur Institute (Paris), at the May 7 meeting of the Academy of Medicine, reported their observations on fifty-seven infants, who were given the BCG vaccine at birth and kept under observation from 1928 to 1935. It was always possible to isolate tubercle bacilli of the human type from lesions found in infants who had been given the BCG vaccine but who had been raised in an environment in which they were exposed to tuberculous infection. These infants were contaminated in spite of having been vaccinated. This, according to Negre and Valtis, excludes the possibility of a recrudescence of the virulence of the filtrable virus in the

BCG vaccine. Bacteriologic examination of the pus from suppurating lymph nodes in twenty-one infants, immunized by the buccal route, gave the following results. In thirteen of the twenty-one, no pathogenic germs were found, in six cases only ordinary pyogenic organisms, in one case (the child had been in contact with a case of virulent tuberculosis) and a second case, only acid-fast bacilli were found. The inoculation of which into guinea-pigs failed to result in evidences of tuberculous infection. Eighteen infants who were given the BCG vaccine at birth have died of various intercurrent disorders. At necropsies on these children it has never been possible to find either in the alimentary tract, lymph nodes or solid viscera any virulent strain of tubercle bacilli to which death could be attributed. Thus, in not a single case has it been possible to find that any accidents reported as occurring in infants vaccinated at birth were due to a recrudescence of the virulence of the filtrable virus contained in the BCG vaccine.

Intermittent Hemiplegias Due to Spasm of Cerebral Vessels

Tinel and Pottier call attention in a paper published in *La pratique médicale française* to a form of transitory hemiplegia not infrequently observed in apparently normal young persons in whom there is no evidence of syphilis or of arterial changes, such as hypertension or sclerosis, as well as absence of uremia or cardiac disease. The only way such cases can be explained is that they are due to a vascular spasm. Such an explanation may suffice for intermittent, transitory hemiplegia that is observed in cases of cerebral tumors, syphilis of the central nervous system and atheroma. These temporary hemiplegias occur more commonly than has been generally supposed.

Does Tracheobronchial Adenopathy Exist in Children?

Lestocquoy in the May 5 issue of the *Concours médical* answers negatively, so far as a nontuberculous infection is concerned, whether tracheobronchial adenopathy really exists in children. The only conditions under which one encounters such nontuberculous enlargements of the tracheobronchial lymph nodes is in Hodgkin's disease, lymphosarcoma and mediastinal tumors. In tuberculosis the adenopathy never occurs alone but is accompanied by pulmonary lesions. Tuberculosis of the lymph nodes at the hilus is found in three forms.

1. Caseation of the bronchial lymph nodes during the first year of life. The concomitant pulmonary lesions are usually minimal. When the lymph nodes are very large and the pulmonary lesions small, the prognosis is not favorable. The diagnosis is based on the stridor and a "bitonal" cough accompanied by loss of weight and appetite and a positive skin reaction. Radiography is the best diagnostic method and enables one to see a convex contour on each side of the trachea or a dark band of right sided parasternal shadow. These cases frequently terminate in meningitis or a generalized miliary tuberculosis.

2. Enlargement of the bronchial lymph nodes of young children. This occurs associated with adjacent small pulmonary tubercles. It should be looked for in all children who have a positive skin reaction. Here radiography is virtually the only method of diagnosis, because percussion is unreliable. One sees the juxtatracheal, juxta-aortic and, in profile, real mediastinal shadows. The prognosis is more favorable than in the first group. Many of these nodes seem to disappear gradually under appropriate treatment.

3. Calcification of the bronchial lymph nodes. This is the most typical group and is observed in older children who are fretful and poorly nourished and who have at intervals slight febrile attacks. The physical examination is not of much aid, the condition exists almost without any clinical signs. The radiologic observations, however, are typical, in the form of uniformly dark shadows at the pulmonary hilus, surrounding the bronchi. In spite of representing an apparently healed lesion,

these calcified nodes represent a latent stage of tuberculosis from which virulent bacilli frequently enter the circulation in adolescents and adults. From these peribronchial lymph node foci arise the pulmonary lesions in the majority of cases.

Popular Medicine in Germany

The nature cure movement, which under the new regime in Germany receives strong support, was recently given a new impetus toward a wider development. From May 12 to May 26 an exposition of German popular medicine, which enjoyed the protection of the district leader Julius Streicher, was held in Nuremberg. The protracted session brought together the supporters of all trends and groups representing "popular medicine" and "life reform" and resulted in an enthusiastic demonstration. That in this movement political and so-called racial points of view play a great part is well known. Researches into the family histories of leading German investigators with a view to discovering a strain of non-Aryan blood in their ancestry are now popular, the ultimate aim being to discard rational scientific methods in the treatment of disease (syphilis, for example) and to substitute hydrotherapy and herbal treatment, homeopathy and the like. The movement claims to have 12,000,000 adherents in Germany, and almost a million families organized in the "gesundheitsvereine," or health clubs. The demonstration culminated in the Reichstagung der Deutschen Volkshelbewegung, at which Dr. Wagner, the present fuhrer of German medicine, gave several speeches in which he outlined programs for the future of German medicine. The most significant thing about the session as the official *Deutsches Aerzteblatt* points out, is the fact that in Nuremberg the foundation was laid for the creation of a new comprehensive system of German medicine that will include both trends, scientific medicine and nature cure practice. In the addresses and papers the well known points of attack on "old school" medicine were again brought out—in some instances by physicians themselves. Thereupon the fuhrer of German medicine announced in a special ceremony the creation of the Reichsarbeitsgemeinschaft der Verbände für naturgemässe Lebens- und Heilweise and of the Reichsarbeitsgemeinschaft für eine neue deutsche Heilkunde. The last mentioned merger will take upon itself the task of providing training in the new system of medicine and of creating suitable chairs at the universities. Leadership in the new movement was entrusted to Dr. Kötschau, professor of nature cure practice at the University of Jena. The merger first mentioned, that for nature cure and the natural mode of living, is designed to bring together the lay groups that support the movement and to strengthen among the people their understanding for biologic therapeutic methods. With this merger will be affiliated the Biochemischer Bund Deutschlands, the Felke-Bund, the Reichsbund für Homöopathie, the Kneipp-Bund, the Deutsche Gesellschaft für Lebensreform, the Priessnitz-Bund, and the Schüssler-Bund der Biochemiker. The character of the constituent elements reveals the nature of the task proposed. The following citation from an address of the fuhrer of German medicine illustrates his point of view: "A materialistic age was so arrogant as to imagine that the eternal secrets of life may be fathomed with the aid of the exact natural sciences alone. One must not suppose that in a period of so great mental storm and stress such as we are passing through the great revolution will stop short before the gates of the German universities or before the barriers erected by their scientists. The foundation for the new system of medicine cannot be the exact natural sciences but only the national-socialist world views concerning the natural and fundamental biologic 'laws' controlling all events. It is by no means part of our conception that the old school

medicine should be entirely rejected or that the technical acquisitions that it has brought us should be renounced. It is our aim to effect a synthesis of the onesided old school medicine and the nature cure methods. We turn aside from the extremists and fanatics of both camps." In spite of all the agitation there was until recently no clinic for nature cure medicine at any German university, but now the Faculty of Medicine of Erlangen has decided to establish such a clinic and to create in association with it a professorial chair.

In addition, the Reichsarbeitsgemeinschaft der Naturärzte (merger of nature cure practitioners) has been created, with which a number of leagues have become affiliated, their character indicating plainly the nature of the merger, for example, the Deutsche Allgemeine Aerztliche Gesellschaft für Psychotherapie, the Deutsche Gesellschaft für Bäder- und Klimakunde, the Zentralverein Homöopathischer Aerzte, the Bund der Kneipp-Aerzte, the Reichsverband der Naturärzte and the Vereinigung Anthroposophischer Aerzte. According to a published utterance of the director of this merger, the nature cure practitioner is helping the German people to bridge the gap to the German physician of the future. In an address before this new merger, Professor Kötschau proclaimed that biologic medicine achieves success in some cases in which old school medicine is at a loss what to try next. He stated further that biologic medicine is ready to show that it possesses effective weapons with which to combat epidemics successfully. It opposes the lack of confidence in and the distortion of nature, which find their expression in exaggerated sterilization, conservation and disinfection measures. It is interesting to note that as eminent a clinician as Professor von Krehl of Heidelberg has expressed his views on nature cure medicine not only in an address before the Heidelberg Medical Society but also in an article in *Therapie der Gegenwart*. While he makes a number of concessions to nature cure medicine, he endeavors, on the other hand, to defend old school medicine, of which he has been, in a sense, an exponent for thirty years or more. He admitted that he had been unable fully to understand the standpoint of the representatives of nature cure medicine in their attitude toward medicines. He had observed that, in adducing proof, it was always certain prominent nature cure practitioners who were cited. Of the mediocre practitioners little or nothing is heard, particularly the many patients who fail to receive any benefit are silent on the subject. It had been his experience that persons of a very definite type, from the standpoint of disease and personality, are adapted to the application of nature cure methods. Patients of this type are sometimes cured by nature cure practitioners after regular physicians have failed. It is evident that suggestion plays an important part in such cases. But that any patient with a grave organic disease had been cured in this manner had not come within his observation. He expressed further the view that, if medical overspecialization and overburdening of physicians could be done away with, it would inure to the benefit of a rational mode of treatment in general. His statements were worthy of attention because of his skilful argumentation.

Seventieth Birthday of Professor Brauer

Prof. Ludolph Brauer, for many years professor of internal medicine and director of the Eppendorf Hospital, celebrated his seventieth birthday, July 1. A pupil of the Heidelberg clinician Erb, he obtained a chair at the University of Marburg, whence he was summoned to the University of Hamburg, where he remained until his retirement. Brauer's fame rests chiefly on his researches in the field of tuberculosis, for example, on the treatment of adhesive pericarditis, in which he recommended the removal of ribs adherent to the pericardium, in order to eliminate the manifestations of cardiac insufficiency. The overpressure procedure in the surgical treatment of the thorax originated with him. For the pneumothorax procedure he

created, through numerous researches, a broad scientific basis and brought it about that this procedure became accepted by those who opposed it. Importance attaches also to his researches on pleural shock and arterial air embolism in connection with the institution of pneumothorax or during the reinsertion process. He supplied the scientific basis for more extensive thoracoplasty. Brauer has reached his goal, in aiding the widespread use of physical and surgical treatment of pulmonary tuberculosis, lung gangrene and bronchiectasis, and in the inauguration of functional tests in all diseases of the thorax by means of ingeniously devised endurance tests. Brauer combined great talent for organization with unusual skill in carrying on negotiations. He succeeded in winning over boards and philanthropists in favor of his plans for the creation of the tuberculosis institute, the department of metabolism, the diet kitchen, the institute for research on light, the institute for medical research in the field of aviation, and others.

Conference on the Problem of Abortion

The Rumanian Medical Association, the Society of Transylvanian Gynecologists and the medical chambers of the counties of Transylvania convoked a congress, which was attended also by many judges and lawyers, to discuss the problem of induced abortion and to draft a new law on criminal abortion. The congress found that

1 The law drafted in 1934 largely satisfies the requirements. The congress approved prosecution for criminal abortion. However the congress voted to appeal to the competent authority requesting a change in the law so that artificial abortion may be permissible from medical, eugenic and ethical points of view. Accordingly the law should not apply to the use of contraceptives, and their sale by druggists should be permitted. 2 Abuse of the eugenic and ethical indications for artificial abortion should be severely punished. The congress held that the paragraph of the law that requires physicians preliminary to performing such operations to notify the police should be canceled. 3 The general council of the Rumanian Medical Chambers should be invited to compile a guide as to the indications and methods of operation. 4 At the investigation of cases of criminal abortion, the presence of a medicolegalist is imperative. 5 If a doctor becomes suspended from practice on account of a gross error in performing the operation or malpractice, he may be allowed to continue practice if he passes an examination before the faculty of medicine of the university. The examination has to be in the subject in which he displayed incompetence.

The National League Against Tuberculosis

The minister of public health referred to the Chamber of Deputies the draft of a law on the organization of the National League Against Tuberculosis. The objectives of the league would be to conduct the antituberculosis campaign, to coordinate existing similar institutions to enlighten the public by adequate propaganda, to train special personnel—physicians assistants, nurses—and to found dispensaries, isolation hospitals, sanatoriums, preventoriums and all institutions necessary in the treatment and prophylaxis of tuberculosis. The king is the president of the council of the league. The administrative body is a central managing committee of seven members elected for five years. The income of the league would be 60 per cent of the net profit from the state lotteries, 60 per cent of the revenue derived from the taxes on cosmetics and proprietary medicines (5 per cent ad valorem duty, paid by the pharmaceutical manufacturers on imported foreign specialties), 10 per cent of the revenue from the manufacture of narcotics, and 2 per cent of the profit earned by the state alcohol monopoly. In addition, all public institutions engaged in treating the sick

—for example, the social insurance office, the sickness club of the state railways, and private sickness clubs—will have to contribute annually to the campaign against tuberculosis. The branches of the league will get subsidies from the counties, cities and villages. The budget of the league will be subject to approval and control of the chamber of deputies. The medical positions will be temporary. All physicians will be appointed for two years, after the lapse of which time their positions will be surrendered to younger men, that these may have competent training in the prophylaxis and treatment of tuberculosis. These physicians will not receive pay, excepting their board, in hospitals and sanatoriums. Professor Cantacuzino, a zealous promoter of the antituberculosis movement, has been untiring in preparing the soil for the establishment of the national anti tuberculosis league.

Infant Mortality in Bucharest

According to the last annual report of the demographic bureau the most conspicuous phenomenon in connection with the increase of population is the rapid increase of mortality in the last year. Of 1,000 infants born alive, fourteen die within the first year.

There were 87,824 marriages in the country and 914 divorces. The most unfavorable position is in Bucharest. While the birth rate decreased considerably, the death rate increased. In May 1935 the number of births was 1,073 while the number of deaths amounted to 1,051. Infant mortality is still more unfavorable. In Bucharest, 23 per cent of all infants die under the age of 1 year. There are two other Rumanian towns in which infant mortality is similarly high, namely, Jassy, the capital of the province of Moldavia, where it is 26 per cent, and Tighina, close to the Russian frontier, where it is 27 per cent.

Public health conditions in general were better in 1934 than in 1933.

Regulation of the Use of the Term Radiologist

The Bucharest Association of Radiologists, at a recent meeting, gave expression to the opinion that the time has come when steps should be taken to prevent the use of x-ray apparatus by those whose capabilities are insufficient. At present, any physician may purchase and use x-ray equipment for diagnostic and therapeutic purposes. The frequent accidents that have occurred, one of them fatal, makes it imperative that some discrimination be made. The association would not object if private practitioners used x-ray equipment for their own patients for diagnostic purposes, but no one excepting competent radiologists should make x-ray reports that may serve as a ground for operations. High voltage therapy, which is dangerous even in the case of well trained radiologists, should be applied only by radiologists who have passed special examinations proving their fitness. The association sent a memorandum to the Central Medical Chamber to elaborate the draft of a new enactment prescribing the qualifications of a physician who is to practice as a radiologist.

Observations of Effect of Radio Waves on Employees

Some time ago W. W. Parker, an English physicist, stated in a treatise that the radiations of radio broadcasting stations are apt to cause neurasthenia and certain other abnormal states of the nervous system. Prof. Dr. Francis Porsche of the Cluj University has made extensive investigations into this subject. He says that as a check on the probability of the correctness of the statements of Parker he made thorough investigations at several radio stations. He examined individuals who are employed at the transmitting stations and who are exposed in a concentrated measure to the actions of the radio waves. Such observations on the employees as he made, says Professor Porsche, and those of physicians employed at such stations for many years, did not corroborate Parker's assumptions.

AUSTRALIA

(From Our Regular Correspondent)

July 11, 1935

Tuberculosis Campaign in Australia

The federal health council has drawn up plans for a nationwide effort to combat tuberculosis. These recommendations will be forwarded to each state health department to the end of securing uniformity of action. In Australia each year, tuberculosis kills 3,000 people, two thirds of them being under the age of 45. The rate keeps fairly constant at 45 per cent of total deaths. The age of death is at a maximum in the 30-40 age group for females, and the 40-50 age group for males. It is seventh in order of importance as a cause of death, being preceded by heart disease, cancer, nephritis, senility, accidents and diseases of early infancy, in that order.

The federal health council considers that the economic factor is the most important aspect of the campaign against tuberculosis. The wage earner of a family frequently will not leave his family as long as he is able to contribute anything toward its support. Possibly the greatest of the advances toward an effective control of tuberculosis would be the introduction of some system for providing economic conditions of at least a bare living standard for the family, to enable the affected wage earner to enter a treatment institution as early as possible. The amount of 17/6 per week paid under the invalid pensions act is not more than a partial relief of the inevitable economic distress in a home in which there is a member with tuberculosis. The attention of the commonwealth government is directed to the fact that before a person can receive an invalid pension he must be certified as permanently and totally incapacitated, whereas in every early case of tuberculosis the hope for which there is reasonable ground, is that there will be a cure. If possible it would be desirable to alter the wording of the pensions act in relation to tuberculosis.

The compulsory notification of all forms of tuberculosis is considered to be essential to success in the campaign against tuberculosis. It is strongly recommended that there be an adequate fee for such notification and that in any case arrangements be made for payment direct to the notifying physician without cumbersome procedure. It is considered essential to have a full-time tuberculosis officer in every state. Periodic medical examination of all persons in the community should be encouraged. An effective organization should exist in every state for the periodic examination of house and family contacts of a patient with tuberculosis, when necessary, without charge to the persons examined. The examination of sputum should always be available without charge at the request of any medical practitioner.

A practical method of providing skilled supervision of cases and contacts, of providing consultant advice to all medical practitioners and of educating the public, would be to provide a mobile tuberculosis unit.

It is regarded as of primary and immediate importance to establish an effective system where it does not now exist for the earliest possible treatment of early cases. When conditions are entirely suitable but not otherwise, there are advantages in home treatment that should not be overlooked. Legal power should be available when necessary, for compulsory isolation in advanced cases in which the conditions involve danger to the public health. It is desirable to bring into effect, and maintain separation of the advanced and hopeless cases from cases with prospect of cure. Probably the best method of achieving this is hospital accommodation under the same management as that of the sanatorium.

The conference believed that for the success of the campaign against tuberculosis it is desirable to establish close cooperation between health departments, education departments, hospitals, the medical and nursing professions, local government authorities and all other agencies concerned. Especially is

cooperation between health departments and the commonwealth pensions department necessary. The work being done by the Red Cross homes and similar institutions in building up the resistance of children was greatly commended, but the conference believed that the work of these establishments would be considerably improved in extent and value if the authorities would agree to admit children who, although known to be infected with tuberculosis, have been certified by a selected medical officer as not infective. The provision of preventoriums at which may be treated persons who have been exposed to infection and whose health and environmental conditions are unsatisfactory is an essential link in the chain of preventive measures.

The Spread of Tumors in the Human Body

R. H. Willis of the Baker Institute of Medical Research, Melbourne, has reviewed the literature and recorded personal and meticulous observations of 323 necropsies in cases of malignant disease. It is felt that this book, published by J. & A. Churchill of London, will for years be a standard work of reference. Willis clears up many pathologic pitfalls. He strongly doubts the entity of primary endothelioma of the lymph gland and considers these tumors usually carcinomatous metastases. He decries the possibility of specific premetastatic changes in lymph glands and of tumor cells being destroyed in lymph glands. He draws attention to the distinction that exists between the phenomena of contiguity invasion and metastasis. He refutes the hypothesis of tumor cell implantation of contact or "kissing" cancers on epithelial surfaces. The adherence and departures from structural types in metastases are indicated, and the literature covering the interesting occurrence of spontaneous retrogression of tumors is reviewed and our ignorance of some deeply underlying biologic laws indicated. In view of the unfortunate absence of pain in early malignancy it is interesting to note Willis's inability to demonstrate nerve fibers (that were not included residues) in tumor cells and their stroma. In 7 per cent of his series of necropsies, metastatic growths had been clinically mistaken for the primary. Attention is directed to the effect of these errors on statistical figures. The important clinical question of the safety or otherwise of the biopsy incision he settles by stating that the risk is negligible. The only dangers are (a) implant tumors when healthy skin is cut through and (b) dissemination aggravation by rough handling. It is advisable, however, to proceed with the radical treatment, if called for, within a few days.

Shark Acts as Detective

Medicolegal experts in Sydney are involved in a case that sounds more like fiction than a real life and death problem. The story starts on the ocean beach at Sydney, where some fishermen had set a bait for a man-eating shark that had been roaming up and down the surfing beaches. The shark did not take the bait but became so hopelessly foul of the line that it was hauled ashore alive. The shark was then taken alive to the large sea-water pool in the aquarium at the Sydney Zoological Gardens. For a few days the shark was listless and appeared ill. Suddenly, however, it became excited, thrashed the water into foam, and to the horror of several casual onlookers vomited a human arm. The limb was recovered from the pool and a close examination revealed some tattoo marks of a type that sailors adopt for the adornment of their bodies. Police inquiries were made toward identification of the arm and by means of the tattoo marks it was recognized as belonging to James Smith, a sailor. Further inquiries elicited the news that about April 8 this man went fishing in a boat with one Patrick Brady and that the latter returned alone. It now appears that Smith was murdered by Brady in the boat and that his body was dismembered and thrown into the water. A startling sequel was the murder of the chief witness in the case, William Holmes, a boat builder

This man was taken for a ride in his own car and shot. The car containing the body was found in a lane in the shadow of the great North Shore bridge at Sydney.

The Menace of the Cat

In the editorial comment in *THE JOURNAL*, April 30, 1932, entitled "The Menace of the Cat" appears the statement that "millions of domestic cats gone wild are said to inhabit Australia and are rapidly destroying the bird life of that continent." While there are many instances in this country of primarily domestic animals "going bush" and becoming a menace, the cat is not a serious problem. The chief problem is the dog, who becomes a dingo and causes havoc among the sheep pastured in the outback country. To a lesser extent the horse becomes a "brumby." The damage he does is tempting the ranch horses to escape. The health hazards that the cat introduces are mainly skin diseases of the trichophyton type, infected scratch marks and, indirectly, strychnine poisoning of children from the baits that are placed for the destruction of the animal. While cats destroy birds, their activities are not of any moment to the avian life of the country.

NETHERLANDS

(From Our Regular Correspondent)

July 17, 1935

Traffic Accidents During 1932

The Central Bureau of Statistics has published for the first time a monograph giving detailed information on the causes of traffic accidents. All accidents on the public highways that caused substantial material damage and resulted in the death or injury of human beings are taken into consideration. The work reveals that in a total of 41,195 accidents the driver was responsible in 28,221 instances and the pedestrian was at fault in 2,975 cases. In 2,788 cases the bad condition of the road was the cause of the accident. In addition, there were 6,254 "diverse" causes. Collisions between bicycles or between a bicycle and other vehicle are most frequent, because of the large number of bicycles on the streets. To enumerate: There were 381 instances of a collision between a bicycle and a street car, 3,564 collisions between a bicycle and a truck, 7,336 with an automobile, 981 with a motorcycle, 2,928 with another bicycle, 145 with a pedestrian, 150 with a pushcart, and 559 with a horse-drawn vehicle.

Of collisions of an automobile with a street car there were 851 instances, with a truck, 3,215, with another automobile, 4,582, with a motorcycle, 1,067, with a bicycle, 7,336, with a pushcart, 556, with a horse drawn vehicle, 835, and with a pedestrian, 1,441.

Of collisions of a truck with a street car there were 728 instances, with another truck, 1,617, with a motorcycle, 447, with a bicycle, 3,564, with a horse-drawn vehicle, 611, with a pushcart, 427, and with a pedestrian, 739. One should take account of the fact that 94 per cent of the vehicles were bicycles, 156 per cent were trucks, and 274 per cent were automobiles.

The source of information concerning the fate of persons seriously wounded is not reliable. Many communes have no infirmary. The wounded in that case are transported to the nearest city, where the consequences of the accident are often lost sight of.

First Aid Stations Along the Highways

A society has been recently organized in the Netherlands for the purpose of establishing 2,550 first aid stations along the principal highways at intervals of approximately 5 kilometers (3 miles). The administration of the work of the society has been entrusted to Dr. J. G. Van Turenhout. At each station there is a telephone, which enables an injured person to get in touch with a physician, police station, sanitary service, the clergy, or other connections. The station consists essentially

of a large square box, which contains a small supply of bandages ready for immediate use. There is also a larger box of dressings for the use of the physician. A folding stretcher, of special construction, makes it possible to transport an injured person in an automobile. The medical control of this new service will be entrusted to the Red Cross, in collaboration with the Orange Cross. A large number of physicians have expressed their willingness to cooperate with the members of this society.

Convention on Aviation Medicine

The draft of legislation approving an international sanitary convention in relation to aviation was recently submitted to the general assembly. The convention was drawn up by the international sanitary bureau, the headquarters of which is at Paris, and will consider what measures should be taken to prevent the dissemination of contagious diseases through aviation. The endorsement of the Netherlands is manifested by the fact that the aviation centers at Schiphol, Weelhaven, Schellingwoude, Flushing and Twente are to have a "health organization" that will adopt all measures necessary to prevent the spread of contagious diseases. A physician will be available for each center of aviation. If circumstances seem to require it, passengers and crew will be subjected to a medical examination before the departure of each plane. Authority to embark will be refused to any person who presents symptoms of a contagious disease. A rapid enforcement of the terms of the convention is to be desired. It has been found acceptable in all respects to the Dutch East Indies. As for Surinam and Curaçao, the expense involved will be too high for those countries.

Tuberculosis in Schools

The large number of cases of contagion from tuberculosis occurring in certain schools last year has shown the absolute necessity of adopting preventive measures.

The draft of a law the purpose of which is to protect school children against contagious diseases that are likely to be communicated to them by the instructional corps has been submitted. The law would require applicants for positions in schools to present a medical certificate attesting that they are not affected with open or active tuberculosis. Periodic medical examinations of the instructing personnel are associated with difficulties by reason of the excessive number of persons who would be required to submit to the examination. The measure will probably be just as effective if all the suspicious cases are reexamined by the health officers of each commune.

Several articles that have appeared were conceived with the purpose of removing from the schools all persons who are not holders of a health certificate. If, after a certain length of time, teachers who are removed are not reinstated, they will be subjected to a medical examination and will be pensioned.

The government admits the justice of according a new medical examination to every person dismissed who makes such a request. The sanitary commission appears fitted to organize such sanitary control.

Marriages

PAUL S. SLOAN, Charlevoix, Mich., to Miss Alta La Verne Zimmerman of Oberlin, Ohio, June 17.

JAMES STANLEY SMITH to Miss Eleanor Dexter Mussina, both of Williamsport, Pa., June 7.

JUSTIN ANTHONY ROGERS to Miss Alice Jane Vessey, both of San Francisco, August 14.

EUGENE C. EPPINGER, Boston, to Miss Catherine Codman at Westwood, Mass., July 13.

MORRIS ZIMMERMAN to Miss Estelle Keller, both of New York, August 20.

NED CAMP Atlanta, Ga., to Miss Julia Thompson of Barnesville June 15.

Deaths

George Hughes Kirby, professor of clinical psychiatry at Cornell University Medical College, New York, died suddenly August 11 at Wentworth-by-the-Sea, Portsmouth, N. H., aged 60. Dr Kirby was born at Goldsboro, N. C., in 1875. He received a bachelor of science degree from the University of North Carolina in 1896 and doctor of medicine from the Long Island College Hospital, Brooklyn, in 1899. From 1902 to 1908 he was associate in clinical psychiatry at the Psychiatric Institute in New York, he was director of the institute from 1917 to 1931 and he planned the New York State Psychiatric Institute and Hospital as a unit of the Columbia-Presbyterian Medical Centre. From 1908 to 1917 he was director of clinical psychiatry at the Manhattan State Hospital. During the World War he served in the Army medical corps and since the war has been consultant in neuropsychiatry for the United States Public Health Service. In 1921, he was appointed by the Secretary of the Treasury a member of the Board of Consultants to Develop Hospital Facilities Throughout the Country for Ex-Soldiers. He was professor of psychiatry at the University and Bellevue Hospital Medical College from 1914 to 1917, Cornell University Medical College from 1917 to 1927 and the Columbia University College of Physicians and Surgeons from 1927 to 1932. He was a member of the Medical Society of the State of New York, the American Neurological Association, the Association for Research in Nervous and Mental Disease and the National Committee for Mental Hygiene. Dr Kirby was a past president of the American Psychiatric Association, the New York Neurological Society, the New York Psychiatric Society and the New York Society for Clinical Psychiatry. He was a member of the medical council of the Veterans' Administration, Washington, D. C., consulting psychiatrist to the Presbyterian Hospital, New York Psychiatric Institute and the New York Neurological Institute. He was a member of the medical advisory committee of the New York State Hospital Development Commission. Dr Kirby was also associate editor of the *American Journal of Psychiatry* and was on the editorial board of the *Psychiatric Quarterly*.

Cornelius Van Zwaluwenburg of Riverside, Calif., University of Michigan Department of Medicine and Surgery, Ann Arbor, 1885, member of the House of Delegates of the American Medical Association, 1919-1923, past president of the California Medical Association and formerly counselor of the first district past president and secretary of the Kalamazoo (Mich.) Academy of Medicine, fellow of the American College of Surgeons, on the staff of the Riverside Community Hospital, aged 72, died, July 23.

John Murray Johnson of Bridgeport Conn., Long Island College Hospital, Brooklyn, 1895 past president of the Fairfield County Medical Society, member of the New England Obstetrical and Gynecological Society, fellow of the American College of Surgeons, formerly member of the board of education, on the staff of St. Vincent's Hospital, aged 61, died, July 2.

James Cornelius Gill, Chicago, Rush Medical College, Chicago, 1890, professor of clinical neurology at his alma mater, member of the Central Neuropsychiatric Association, on the staffs of the Presbyterian Hospital, Cook County Psychopathic Hospital and the Illinois Masonic Hospital, aged 69, died July 1, in the Washington Boulevard Hospital of uremia.

Walter Beran Wolfe of New York, Washington University School of Medicine, St. Louis, 1924 at one time served in the medical corps of the U. S. Navy, formerly psychiatrist of the Children's Court of Manhattan, author of a recent book entitled "A Woman's Best Years", aged 35, was killed, August 15, at Martigny, Switzerland, in an automobile accident.

William Matthew Kenna, Washington, D. C., Yale University School of Medicine, New Haven, 1892, assistant in clinical medicine, 1897-1898, and assistant in neurology 1900-1904 at his alma mater, served during the World War, aged 66 on the staff of St. Elizabeth's Hospital, where he died, July 1, of heart disease.

John Arthur Turner, Cincinnati, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois 1909, member of the Ohio State Medical Association, served during the World War, aged 51, died June 19 in the Deaconess Hospital, of coronary thrombosis and arteriosclerosis.

Homer Brush Jones, Brooklyn, University of the City of New York Medical Department 1891, member of the Medical Society of the State of New York, for many years connected

with the health department, on the staff of the Brooklyn Eye and Ear Hospital, aged 69, died, July 27, in the Brooklyn Hospital.

Gayle Aiken, New Orleans, Tulane University of Louisiana Medical Department, New Orleans 1891, Hahnemann Medical College and Hospital, Chicago, 1892, formerly secretary of the Homeopathic Board of Medical Examiners, aged 75, died, July 20, in the Baptist Hospital, of carcinoma of the prostate.

Frank Adelbert Southwick of Stevens Point, Wis., Medical School of Maine, Portland, 1881, for many years member of the school board, formerly health officer of Stevens Point, aged 77, on the staff of St. Michael's Hospital, where he died, July 23, of pulmonary embolism.

John W. Hermetet of Macomb, Ill., Chicago Homeopathic Medical College, 1896, formerly secretary of McDonough County Medical Society, medical director of the Marietta Phelps Hospital, aged 63, died, August 4, in the Memorial Hospital, Buffalo, of pneumonia.

William Jennings Bryan McAuliffe of Juneau, Alaska, University of Louisville (Ky.) School of Medicine, 1926, served during the World War, surgeon in charge of the United States Hospital for Natives, aged 38, was found dead, July 4, of coronary thrombosis.

Fred Wood Phifer of Wheatland, Wyo., University of Maryland School of Medicine, Baltimore, 1902, formerly secretary of the Platte County Medical Society, on the staff of the Wheatland General Hospital, aged 58, was killed, May 31, in an automobile accident.

Richard Ernest Poole, Veterans Home, Calif., University of Maryland School of Medicine, Baltimore, 1892, member of the California Medical Association, on the staff of the Veterans Home Hospital, aged 58, died, June 13, of chronic myocarditis.

John Hillman McLain, Jackson, Miss., Jefferson Medical College of Philadelphia, 1913, served during the World War, formerly on the staff of the Mississippi State Charity Hospital, aged 47, died, June 6, in a local hospital.

Stewart Vernon Irwin of Oakland, Calif., Johns Hopkins University School of Medicine, Baltimore, 1915, fellow of the American College of Physicians, served during the World War, aged 44, died, July 1, in San Francisco.

Otto Hensel of New York, Columbia University College of Physicians and Surgeons, New York, 1900, on the staff of the Lenox Hill Hospital, aged 59, died suddenly, July 14, in Honesdale, Pa., of coronary thrombosis.

Henry Charles Schomberg Elliot, Toronto, Ont., Canada, Trinity Medical College, Toronto, 1888, L.R.C.P., Edinburgh, Scotland, 1893, served during the World War, aged 68, died, July 1, in the Toronto General Hospital.

Allen Lewis Krepps, Pittsburgh, Western Pennsylvania Medical College, Pittsburgh, 1897, member of the Medical Society of the State of Pennsylvania, aged 63, died, June 24, of chronic myelogenous leukemia.

James Monroe Smith, Watertown, N. Y., University of the City of New York Medical Department, 1889, member of the Medical Society of the State of New York, aged 72, died, May 10, of angina pectoris.

Menzo White Herriman, Long Island City, N. Y., Syracuse University College of Medicine, 1881, member of the Medical Society of the State of New York, aged 77, died, July 26, of carcinoma of the bladder.

George Noble Macomber, Denver, Pulte Medical College, Cincinnati, 1878, associate member of the Colorado State Medical Society, aged 81, was found dead, July 15, of angina pectoris and chronic myocarditis.

Jean Philippe Auguste Martin, Montreal, Que., Canada, School of Medicine and Surgery of Montreal, 1904, formerly on the staff of the Hotel Dieu Hospital, Campbellton, N. B., aged 58, died, April 1.

Mary Scott Jones, Boston, Woman's Medical College of Pennsylvania, Philadelphia 1892, member of the Massachusetts Medical Society, aged 80, died, June 16, in the New England Deaconess Hospital.

Roy McMillan Wheeler, Sycamore, Ill., Northwestern University Medical School, Chicago 1900, member of the Illinois State Medical Society, aged 64, died, May 19, of carbon monoxide poisoning.

William Henry Taylor, Chicago, Bennett College of Eclectic Medicine and Surgery, Chicago, 1904, served during the World War, aged 56, died, June 18, of heart disease and chronic nephritis.

Thaddeus M McNamara * Bakersfield, Calif., Cooper Medical College, San Francisco, 1905, past president of the Kern County Medical Society, aged 54, died, July 15, of coronary occlusion

Joseph Stanley Swoboda, Butte, Mont., University of Nebraska College of Medicine, Omaha, 1927, member of the Medical Association of Montana, aged 38, died, June 26, of acute myocarditis

Louis Adolph Grimme * Chicago, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1891, aged 70, died, July 21, of myocarditis and coronary sclerosis

Charles Vernell High Sr, Midland, Mich., Starling Medical College, Columbus, 1888, member of the Michigan State Medical Society, served during the World War, aged 69, died, June 15

George Robert Taylor, Clinton, N. Y., University of Michigan Department of Medicine and Surgery, Ann Arbor, 1886, aged 75, died, May 11, of carcinoma of the colon and peritoneum

Charles Ridgway Blundell, San Gabriel, Calif. (licensed in New Jersey in 1894), veteran of the Spanish-American War, aged 66, died, June 25, of cerebral hemorrhage and bronchopneumonia

Goldie Dean Tyler, Jackson, S. C., Medical College of the State of South Carolina Charleston, 1896, aged 64, died June 1, in the University Hospital, Augusta, Ga., of lobar pneumonia

Oswald B. H. Bowser, Richmond, Va., Howard University College of Medicine, Washington, D. C., 1901, aged 55, died, July 6, of coronary embolism chronic myocarditis and nephritis

Joseph McGowan Harrigan, Wilkes-Barre, Pa., Temple University School of Medicine, Philadelphia, 1928, member of the Medical Society of the State of Pennsylvania, aged 33, died, June 15

James Clair Glasser * Blairsville, Pa., Medico Chirurgical College of Philadelphia, 1914, aged 48, died, May 18, in the Allegheny General Hospital, Pittsburgh, of streptococcal endocarditis

Jonathan O. Torrence, Hot Springs National Park, Ark., Meharry Medical College, Nashville, Tenn., 1917, aged 45, died, May 9, of pulmonary tuberculosis and cirrhosis of the liver

Robert M. Tafel, Phoenix, Ariz., Bennett College of Eclectic Medicine and Surgery, Chicago, 1895, aged 76, died, July 3, in Williams, of myocarditis and coronary thrombosis

Sam E. Rees, Purvis, Miss., Memphis (Tenn.) Hospital Medical College, 1902, member of the Mississippi State Medical Association, aged 64, died, July 2, of carcinoma of the lung

William Ernest Hubbert, Dallas, Texas, University of the South Medical Department, Sewanee, Tenn., 1901, served during the World War, aged 55, was shot and killed, July 31

Jessie Amelia Birnie, Peterborough, Ont., Canada, Trinity Medical College, Toronto, 1898, aged 77, died, June 17, in San Rafael, Calif., of carcinoma of the transverse colon

Elias Mortimer Duffield, Glassboro, N. J., Jefferson Medical College of Philadelphia, 1899, formerly mayor and president of the board of education, aged 60, died, June 27

William Vaux Ewers, Somerset, Bermuda, University of Pennsylvania Department of Medicine, Philadelphia, 1894, served during the World War, aged 63, died, July 4

Harper W. Robertson, Waelder, Texas, University of the City of New York Medical Department, 1890, aged 71, died, May 3, of coronary thrombosis and chronic myocarditis

Oran Merton Belfry, Lansdowne, Pa., Trinity Medical College, Toronto, Ont., Canada, 1884, L.R.C.P., L.R.C.S. Edinburgh, Scotland, 1884, aged 79, died, July 22

Francis Emerson Johnson, Erving, Mass., Dartmouth Medical School, Hanover, N. H., 1882, member of the Massachusetts Medical Society, aged 78, died, May 1

John S. Strickland, Alice, Texas, University of Tennessee Medical Department, Nashville, 1892, county health officer, aged 69, died, June 15, of pulmonary tuberculosis

John Bates Todd, Syracuse, N. Y., Albany (N. Y.) Medical College, 1874, member of the Medical Society of the State of New York, aged 80, died suddenly, June 23

William S. Yazell, Maysville, Ky., Cincinnati College of Medicine and Surgery, 1891, member of the Kentucky State Medical Association, aged 68, died, June 14

Anderson F. Brown * Malta Bend, Mo., Washington University School of Medicine, St. Louis, 1904, aged 58, died, July 5, in Kansas City, of pulmonary edema

Charles L. Boyd, Greeneville, Tenn., Baltimore Medical College, 1901, aged 58, died, June 19, in the Greeneville Hospital, of angina pectoris and hypertension

Harry Lee Brush, Conneaut Lake, Pa., Starling Medical College, Columbus, 1889, served during the World War, aged 69, died, June 22, of cerebral hemorrhage

Lyle Lester Bristol, Caliente, Nev., Loyola University School of Medicine, Chicago, 1930, aged 30, died, July 5, in Los Angeles, of melanosis

William Joseph Love * Opelika, Ala., Atlanta Medical College, 1882, past president of the Lee County Medical Society, aged 75, died, June 29

Levi Abram Sherk, Avon, Pa., University of Pennsylvania Department of Medicine, Philadelphia, 1873, aged 84, died, May 21, of cerebral hemorrhage

Charles William Marlatt, St. Thomas, Ont., Canada, Trinity Medical College, Toronto, 1872, M.R.C.S., England, 1872, aged 89, died, May 31

Elizabeth C. Zindel Taylor, Paris, Texas (licensed in Texas under the act of 1907), died, June 21, of a streptococcal infection of the lower lip

Charles Lemaire, Ste. Clothilde de Horton, Que., Canada, Victoria University Medical Department, Coburg, Ont., 1890, aged 70, died, March 27

Walter S. Wallace, Long Beach, Calif., College of Physicians and Surgeons, Keokuk, Iowa, 1878, aged 83, died, June 4, of valvular heart disease

Charles Henry Kingsbury, West Brookfield, Mass., University of Vermont College of Medicine, Burlington, 1899, aged 68, died, June 26

Mary Bird Bowers, Los Angeles, College of Physicians and Surgeons of San Francisco, 1898, aged 83, died, June 30, of cerebral thrombosis

John T. Pitkin, Buffalo, University of Buffalo School of Medicine, 1884, aged 78, died, May 17, of epithelioma of the hand with metastasis

William Henry Porter, Beaver, Pa., Western Pennsylvania Medical College, Pittsburgh, 1897, aged 74, died in June, of cerebral hemorrhage

William P. Thelen, Wilton, N. D., University of Minnesota Medical School, Minneapolis, 1902, aged 59, died, July 19, of heart disease

William Stephen Keegan, New York, Bellevue Hospital Medical College, New York, 1894, aged 84, died, July 26, of chronic myocarditis

Gustav Adolf R. Koerber * Hoisington, Kan., Omaha (Neb.) Medical College, 1897, aged 60, died, May 31, of diabetes mellitus

Joseph Jacobsohn, Memphis, Tenn., University of Louisville (Ky.) Medical Department, 1887, aged 79, died, May 13, of myocarditis

William Stanton Card, Fredonia, N. Y., Denver and Gross College of Medicine, 1903, aged 68, died, July 27, of cerebral hemorrhage

Thomas Eldon Graham, Albany, Mo., Barnes Medical College, St. Louis, 1893, aged 73, died, July 11, of coronary thrombosis

John Alexander Jones, Ottawa, Ont., Canada, Queen's University Faculty of Medicine, Kingston, 1874, aged 80, died, May 15

Rankin S. Reiff, Los Angeles, Jefferson Medical College of Philadelphia, 1907, aged 50, died, June 13, of chronic myocarditis

George Allen Kennedy * Limon, Colo., Denver and Gross College of Medicine, 1906, aged 55, died, June 27, of myocarditis

Wiley E. Sturgis, Los Angeles, Kansas City (Mo.) Medical College, 1897, aged 64, died, June 17, of carcinoma of the rectum

James Edward Rainey, Clarksville, Texas, Kentucky School of Medicine, Louisville, 1904, aged 57, died, June 20

Frank M. Jackman, Mead, Okla., Louisville (Ky.) Medical College, 1891, aged 72, died, June 16, of angina pectoris

Eli James, Fairland, Okla., Joplin College of Physicians and Surgeons, Joplin, Mo., 1881, aged 85, died, July 2

John A. Pennington, Cato, Ark. (licensed in Arkansas in 1907), aged 63, died, June 18, of heart disease

Correspondence

DIAGNOSIS BY CULTURAL METHODS OF RECTAL GONORRHEA IN WOMEN

To the Editor—The excellent results obtained by Dr A Charlotte Ruys in the diagnosis of rectal gonorrhea by cultural methods, as reported in her communication in *THE JOURNAL*, May 18, page 1844, indicate painstaking effort. To clarify my own position. In the article entitled "Rectal Gonorrhea in Women" (*THE JOURNAL*, January 19, p 192) it was stated "In our experience, cultural methods of isolation and identification [of gonococci from the rectum] have been inconclusive in too many instances to justify confidence in them." The value of cultural methods for the isolation of the organism is not questioned, but their application is difficult and the laboratory reports we received evidence this. I am informed by Herrold that the use of the oxydase reaction as emphasized by McLeod and his co-workers might increase the value of cultivation methods when gonococci are associated with a number of other bacteria, as in rectal cultures. The addition of 1 per cent p-aminodimethylaniline hydrochloride to the surface growth is followed by a black appearance of the gonococcus colonies within a few minutes. This procedure may simplify the problem.

To study by cultural methods a series such as I reported, a laboratory technician under competent direction, devoting a major portion of his time, if not all of it to the work would have been needed and such was not available. My experience leads me to believe that a diagnosis can generally be made from smears. The practical aspect of the matter is that such smears should be made from the rectum of women who have genital gonococcal infection and if well stained and properly studied will reveal the gonococci in the great majority of cases if these organisms are present.

CLEMENT L. MARTIN, M.D., Chicago

SUTURE OF STAB WOUND OF HEART

To the Editor—In their article on suture of stab wound of the heart (*THE JOURNAL*, June 1, p 1979) Drs George Benet and Charles Gordon Spivey say "The first recorded attempt to suture a stab wound of the heart was made by Cappelan in 1895." I desire to call to their attention the fact that on July 9, 1893 Dr Daniel Hale Williams, Negro surgeon of Provident Hospital in Chicago, performed a successful surgical exploration of the heart for a stab wound. He recorded this case in the *New York Medical Record* (51:437 [March 27] 1897) under the title "Stab Wound of Heart and Pericardium."

CHARLES H. GARVIN, M.D., Cleveland

ACETYL-BETA-METHYLCHOLINE

To the Editor—In the interest of scientific accuracy, attention should be called to certain misconceptions likely to arise from the report of the Council on Pharmacy and Chemistry on acetyl beta methylcholine (*THE JOURNAL*, July 27, p 281) and the editorial on the same subject (p 284). Both items suggest that this substance was first prepared by Taveau (*Bull 73, Hyg Lab U S P H S* October 1911) and that its pharmacologic properties were first established by Hunt (*ibid* and *J Pharmacol & Exper Therap* 6:477 1914-1915). Since serious doubt on the chemical identity of the compound prepared by Taveau for Hunt was shown by Major and Cline (*J Am Chem Soc* 54:244 1932) who did definitely synthesize acetyl beta-methylcholine and establish its true physical and chemical properties, it seems only fair that the Council at least should refer to Major and Cline's work. Simonart's

statement on the pharmacologic study of the pure compound and Major and Cline's statement on priority of its synthesis perhaps appeared too recently (*J Pharmacol & Exper Therap* 54:105 and 131 [May] 1935) for inclusion in the Council report.

Since the Council presumes to discuss the general physiologic significance of choline derivatives, it would also seem only fair to refer to the excellent review on this subject prepared by G. A. Alles (*Physiol Rev* 14:276 [April] 1934).

C. D. LEAKE, PH.D., San Francisco

Professor of Pharmacology, University
of California Medical School

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address but these will be omitted on request.

TREATMENT OF SYPHILIS

To the Editor—A woman, aged 24 contracted syphilis about February 1933. It was a primary positive case when treatment was instituted (about the beginning of April 1933). Until May 10, 1933 she had received six weekly injections of neoarsphenamine at a clinic. On May 10 and 17 I gave her an injection of 0.6 Gm of neoarsphenamine. From May 4 to June 30 she received twice a week an intramuscular injection of 2 cc of Sol-Bi (Fraissee) and during this time she was on mixed treatment by mouth. Starting on July 10 she was given weekly injections of 0.6 Gm of neoarsphenamine up to September 11. September 18 biweekly injections of iodo-bismutol 2 cc were given until October 16. Starting October 16 she received weekly injections of 0.6 Gm of neoarsphenamine and on the same days that the neoarsphenamine was injected she would be given an intramuscular injection of 4 cc of iodo-bismutol. This was continued until December 11. On December 15 I started her on biweekly injections of 2 cc of bismogenol and continued this treatment until Jan. 29, 1934 on which she was given 0.3 Gm of neoarsphenamine. On February 2 she received 2 cc of bismogenol and on February 5 she received 0.3 Gm of neoarsphenamine. The Wassermann reaction on several occasions prior to this time had been 4 plus but on Jan. 15, 1934, it was plus minus and on February 5 it was again 4 plus. On February 19 she was again started on biweekly injections of bismogenol 2 cc and this was continued until April 6. On April 9 she was started on weekly injections of 0.6 Gm of neoarsphenamine until June 11. A spinal Wassermann test May 7 was reported as negative but the blood was still 4 plus. June 15 she was started on biweekly injections of 2 cc of mercuriosal and during this time was given 30 grains (2 Gm.) of potassium iodide three times a day. These were intramuscular injections but from July 12 to August 16 she was given 4 cc of mercuriosal intravenously twice a week and also was taking the potassium iodide by mouth. From August 20 to October 10 she received weekly injections of 0.45 Gm of neoarsphenamine. From Oct. 15, 1934 to Jan. 5, 1935 she received biweekly injections of 0.2 Gm of thio-bismol intramuscularly. December 11 the Wassermann reaction was 1 plus and on January 8 it was again 4 plus. January 8 I started her on weekly injections of silver arsphenamine 0.2 Gm and am also giving her injections of bismogenol 2 cc. at the same time. Do you advise continuing treatment in this case and if so how long and what treatment should the patient receive? If she should become pregnant would it be necessary to treat her during the pregnancy? Please omit name if published.

M.D. New York

ANSWER.—As near as it can be made out, the patient has had her syphilis about two years. In this period she has received forty-three injections of neoarsphenamine and three injections of silver arsphenamine, making a total of forty-six doses of an arsenical, sixteen injections of a bismuth preparation, with accompanying treatment of an unstated nature by mouth sixteen injections of iodo-bismutol, twenty-six of bismogenol, a bismuth salicylate, eighteen of mercuriosal, and twenty-two of thio-bismol—or a total of 80 bismuth and 18 mercuriosal injections. Continuous therapy has been wisely used. The only criticism that one would have of this therapy would be that the correspondent has not used Council accepted products entirely thus running the risk of using preparations of uncertain contents and actions. This applies to Sol-Bi. With respect to mercuriosal, it has been shown by Sollmann, Schreiber and Cole (Comparative Diuretic Response to Clinical Injections of Various Mercurials in process of publication) that this product has the same type of action as salyrgan and novasurol, a very high and rapid excretion of mercury, which drops rapidly and probably has little or no effect on syphilis. Thus in the period from June 15 to August 15, when the patient was under

therapy with mercurous either intramuscularly or intravenously, one would be forced to conclude that she was practically on vaccination.

A lumbar puncture has been wisely done and nothing found present in the spinal fluid. The chances are that the patient will not develop an involvement of this system in the future.

Probably a careful examination of the cardiovascular system should be made to rule out the possibility of an aortitis, to explain the persistently positive Wassermann reaction on the blood. If this is done and no evidence of cardiovascular disease is found after roentgen examination, one would be inclined to advise simply giving the patient a rest for two months, with plenty of fresh air and good food and regular hours, and then giving her a course of bismuth salicylate intramuscular injections, each 0.1 Gm, for a series of twelve injections once in six months for a period of another year or more, depending on circumstances. After all, the patient and not the syphilis is being treated, and the patient has already had good therapy. In a case like this, which has received good continuous treatment, a fetish should not be made of a positive Wassermann reaction. The Cooperative Clinical Studies have shown that the average patient who gets a total of from twenty to thirty injections of an arsenical and a like amount of heavy metals will probably escape most of the severe ravages of late syphilis.

In regard to the query as to the necessity of treatment during pregnancy, the Cooperative Clinical Group (Syphilis in Pregnancy, *Veneral Disease Information* March 1934) advises the treatment of every syphilitic woman through each pregnancy, whether she is considered cured or not.

THE STERILITY FERTILITY RHYTHM

To the Editor—In the book *The Rhythm of Sterility and Fertility of Women* by Leo J. Latz, M.D. the following statements are made based on the works of Dr. K. Ogino of Japan and Dr. H. Knaus of Austria: 1. The spermatozoa live about two days after being deposited in the mother's body. 2. The unmaturing ovum retains its germinating ability only for twenty-four hours after it leaves the ovary. 3. Conception depends entirely on whether or not the spermatozoon happens to be in the fallopian tube within a day after the ovum has left the ovary. 4. In the twenty-eight day cycle, the periods from the first to the tenth day and from the eighteenth to the twenty-eighth day are totally sterile periods of the woman. I should like to know how medical science regards these statements and how reliable and authentic they are. Kindly omit name.

M.D. Indiana

ANSWER—The statements made by Latz in regard to the fertility-sterility rhythm are subject to controversy.

1. Spermatozoa have been found alive in the fallopian tube of women for as long as three weeks and a half (Dührssen) and two weeks (Fraenkel) after coitus. It has not been proved, however, how long the human spermatozoa retain their fertilizing power. Knaus's experiments were made on lower mammals and this may not be exactly comparable to human conditions.

2. There is available some evidence in favor of the view that the human ovum is fertilizable for only a short time after it leaves the ovary. Allen and his co-workers obtained human ova from washings of the fallopian tubes at operation between the fifteenth and eighteenth days of the menstrual cycle, showing definite signs of degeneration. Too few such observations have been made, however, to serve as conclusive evidence of either the time of ovulation or the life of the ovum.

3. Conception requires that fecund male and female gametes unite in the fallopian tube or in the uterine cavity. While they usually meet in the ampulla of the tube, they may meet, rarely, in the fimbria or even in the ruptured graafian follicle (primary intrafollicular ovarian pregnancy). When the ovum has definitely been proved to live for only twenty-four hours, one may rightly conclude that the spermatozoon must reach the ovum within a day of its expulsion from the follicle in order for conception to occur. The proof, however, is still lacking.

4. There is considerable controversial evidence in the literature on whether or not in the human being there is a definite sterile period. That some women have sterile days is likely, however. Dickenson presented the following evidence of 1,342 cases of women having a regular twenty-eight day cycle, with a history of a single coitus resulting in pregnancy. Conception occurred in 13 per cent during menstruation, in 72 per cent during the first two weeks of the cycle, and in less than 10 per cent in the fourth or premenstrual week. Fraenkel, from a personally observed series, similarly reported that there was no time in the month at which conception has not occurred in some women. Asdell, from a study of 568 cases, showed that the conception curve rose from the first to the eighth day of the cycle, falling first rapidly, then gradually to the eighteenth day, and then falling abruptly to a low level. In the last ten days (premenstrual) he found 10 per cent of concep-

tions, and no complete period of sterility. In the human being it appears that the period of ovulation may be variable, occurring most frequently in the first two weeks of the menstrual cycle. In view of such data the theory of a regular fertility-sterility rhythm in women cannot yet be generally accepted. New data concerning ovulation and conception may be made available in the next decade if careful records are kept of the histories of fertile couples who are willing to follow the Ogino-Knaus program. This may prove or disprove the theory of a sterility-fertility rhythm.

POST TRAUMATIC EDEMA OF HAND

To the Editor—July 3, 1933, a weaver in a cotton mill sustained a contusion in the palm of the left hand getting it caught in the weaving machine. There was a good deal of reaction in the hand. No laceration was sustained. The reaction did not subside. Roentgenograms, which were taken later, revealed a small piece of steel near the head of the second metacarpal. This was removed by a physician but the hand continued swollen particularly along the course of the third metacarpal shaft and most apparent on the dorsum of the hand. This swelling has persisted to the present time. It has been incised twice and no pus obtained. The wounds healing promptly after each incision. Roentgen examination has always been negative for any bony pathologic changes. Foci of infection in the teeth were cleared over a year ago. The prostate was carefully checked by a competent genito-urinary man over a year ago. The tonsils are out and no suspicious tags remain. The Wassermann reaction is negative. General examination gives no other observations. Urinalysis is negative and the blood pressure normal. The patient is a former professional baseball player. At this time there is apparently a generalized swelling of the dorsum of the hand apparently centered about the shaft of the third metacarpal. The patient complains and has always complained of constant pain and the swelling is tender to pressure. There is some discoloration of a bluish character. Kindly omit name.

M.D. North Carolina.

ANSWER—This patient is probably suffering from a group of symptoms, which, for want of a better classification, are grouped under the name "post-traumatic edema." The symptom complex is a fairly common one. It is not possible to state what produces it and how best to relieve it. There is no doubt that repeated additional traumatizations—operative incisions, infection, vigorous massage and excessive manipulation or use of the hand—can accentuate and prolong the disability. Sympathectomy has been advised by some surgeons, but since the exact cause of the symptoms is not known or its exact nature understood it is obvious that such treatment does not rest on any definite logical basis.

Soaking of the hand in warm water for fifteen minutes twice daily, gently washing the hand throughout that period with an abundance of soap suds (a form of simple and gentle massage) and gentle use of the hand have gradually brought about recovery in a certain number of cases. The best indication that such treatment is helpful is a gradual disappearance of the swelling, discoloration and pain. The margin between the most helpful degree of activity and excessive activity is slight, and the patient's impatience to secure improvement frequently leads him to excessive activity in the hope of bringing about recovery. Persistence of pain and swelling usually indicate that the patient is doing too much and that the hand needs more rest and less exercise.

TREATMENT OF TUBERCULOSIS

To the Editor—A man recently came to my attention who developed signs and symptoms of incipient pulmonary tuberculosis a year ago. He was placed in bed for approximately three months. Following this he increased his exercise to the amount of becoming ambulatory. This was associated with a feeling of exhaustion, pleurisy pains and a small amount of coughing. After approximately three months he returned to bed for five months. Recently he has resumed light work. This was followed by abdominal pains, distention and embarrassed breathing. A fairly clear straw colored fluid was removed by paracentesis. There has been a loss of weight of approximately 15 pounds (6.8 Kg.) recently. A few teaspoonfuls of soft cereal causes abdominal cramps. The evening temperature ranges from 38 to 39 C (100.4 to 102.2 F). What is the treatment indicated in this case? Can you suggest any articles or recent textbooks that deal with treatment of this phase of tuberculosis? Kindly omit name.

M.D. Washington.

ANSWER—One would want to know whether there was any more evidence than signs and symptoms of minimal (incipient) pulmonary tuberculosis a year ago. Were x-ray films made of the chest? If there were only signs and symptoms available for making a diagnosis, the chances are approximately 80 to 20 that the disease already was moderately or far advanced, since signs and symptoms are usually late manifestations of pulmonary tuberculosis. To place this patient in bed constituted excellent treatment. Provided x-ray films were made and collapse therapy, particularly artificial pneumothorax, was not indicated. However, if the disease was unilateral and even minimal (incipient) in extent, artificial pneumothorax, in addition to bed rest, should

have given him a much better prognosis. Three months of bed rest alone usually is not enough but might have been adequate had artificial pneumothorax been instituted.

The appearance of symptoms, such as exhaustion, chest pain and coughing when the patient became ambulatory, was excellent evidence that the disease was not under control. This should have been determined by periodic x-ray films, red cell sedimentation tests and differential white cell counts (according to the method of Medlar) before or while graduated exercise was being employed. Being ambulatory for three months certainly did the patient no good. While five months back in bed probably controlled the symptoms, periodic x-ray films and the tests just mentioned would have shown that the lesions were far from being under control. This is a typical history of the tuberculous patient who does not have anything more definite instituted in the beginning than strict bed rest. In every case of minimal, progressive, pulmonary tuberculosis, which is unilateral, artificial pneumothorax should be instituted, since it is the only method of bringing about adequate rest of the diseased part. Lying in bed gives the lung but little rest.

It would now appear that the patient has a definite tuberculous peritonitis. This usually is not a serious condition in itself and the outcome probably will depend largely on the pulmonary disease, that is, its extent, its progressiveness, and the treatment that is possible at this stage. Most certainly the patient should be on strict bed rest, and if the pulmonary disease has not progressed beyond the stage at which artificial pneumothorax is indicated it should be instituted at once.

Heliotherapy administered to the abdomen, through the use of either of natural sunlight or of the mercury quartz vapor lamp, may aid considerably. In some cases oxyperitoneum is helpful. It consists of introducing oxygen or sterile air into the peritoneal cavity. Usually not more than 500 cc is administered at one time. This can be done with ordinary artificial pneumothorax equipment.

The presence of abdominal cramps following a few teaspoonfuls of soft cereal is suggestive of tuberculosis of the intestine. Heliotherapy might prove beneficial also for this condition. All rough food should be removed from the diet. More detailed description of the treatment is to be found in the recent edition of "Pulmonary Tuberculosis," by Fishberg, published by Lea & Febiger, Philadelphia, and "Tuberculosis in the Child and the Adult," by Pottenger, published by the C V Mosby Company, St. Louis 1934.

POISONING FROM SHOE DYE

To the Editor—I have a patient who operates a shoe shining parlor and who apparently is developing an allergy to the dyes. The satin dyes come from the Omega Shoe Polish Company of Los Angeles; the black leather dyes from the Angelus Shoe Polish Company of Los Angeles; and the spray dyes from the S & W Corporation Ltd of Los Angeles. Could you tell me what these dyes contain? I intend to do a series of patch tests on the patient but if any of these contain cyanide do you think it is safe procedure? If it is safe what is the exact technique of testing? Please omit name.

M D California

ANSWER—In some skin clinics patch tests are carried out as a routine with shoe dressing material as a test agent. No reasons are known for apprehension when the quantity of these test materials is kept low. In one university clinic records were found showing tests on one or more products of two of the companies specified in the query. However it is pointed out that certain reactions after patch tests may reflect the effects of direct irritation rather than sensitization. No attempt has been made to detect the precise ingredients of the products of the companies mentioned, instead, reference is made to the constituents common to products of many manufacturers. Despite some protestations to the contrary a fair number of shoe coatings still contain nitrobenzene as an ingredient, sometimes aniline and possibly wood alcohol. The chemicals are, however, more important as sources of systemic disease rather than dermatoses. Orthodichlorobenzene is much used in shoe dyes. Aniline black is a well known coloring agent. Paraphenylenediamine and other diamines find some application in coloring cheap yellow leather shoes. In the *Deutsche medizinische Wochenschrift* (52 451 [March 12] 1926) is a report of cyanide poisoning from an American made shoe cleanser. Dyers of shoe leather redyers of shoes such as in shoe-shine parlors and occasionally wearers of dyed shoes are known to develop skin disorders caused by shoe dyes solvents for such dyes various resins mineral and vegetable waxes and greases entering shoe dressings.

The following is a simple method for patch testing. The skin area (usually the forearm or the thigh) is gently cleansed. A few thicknesses (two or three) of gauze about 1 inch square are prepared. On this gauze is placed the test material either liquid, solid or semisolid. One drop is sufficient particularly

in the case of materials suspected of irritation. The rough equivalent of one drop represents the amount of solid or semisolid material to be applied in the test. At the same time, times water in equivalent amount to the test material is used for control purposes. At other times only the gauze itself is should be covered over with rubber damming or equivalent impervious material. These somewhat larger squares of rubber damming should be held in place by adhesive plaster. Finally a few turns of bandage should be applied. At the end of twenty-four hours, observation should be made for evidences of skin irritation. Unless the irritation is distinctly greater for the test material than for the controls, the test should be regarded as negative.

INFECTION OF SKIN FROM MICA

To the Editor—I am out on the Big Ditch 17 miles from Riverside Calif. We are building the last 7 miles in Mocking Bird Canyon through an old river bottom and it is one wet job. We carry about 400 men on our rolls all the time. We do have one time with boils and infection from mica. It will penetrate the hands and after two days a terrible infection will develop. It acts in a peculiar way seeming to bore right in through the skin and forming blebs which swell up and fill with fluid in size from a dime to a quarter. We blame lack of care the men take of themselves for the boils or rubbing of oil. Have you any suggestions? Where can I find discussion of the subject? I am interested how to prevent such occurrences.

ROBERT M DOWNSWORTH M D Perris Calif

ANSWER—Mica is, or may be similar to asbestos in its chemical nature. In the case of asbestos, it has been known that skin injuries after abrading contact lead to more than ordinary effects from mechanical injury. It is assumed that asbestos implanted in or beneath the skin exerts fibrogenic action such as is well known to take place in the lungs and peritoneum. A similar action possibly may be associated with mica, but this is not fully proved. It is not tenable to attribute "boils and infections" directly to mica. However, the cutting action of particles of mica may pave the way for the entry of infecting organisms.

California has the reputation of harboring a variety of fungus agents conducive to dermatoses. Because of the nature of the work described, invasion of the skin of the workers by mycotic agents is believed to be a reasonable possibility. On this account it is suggested that appropriate laboratory work be procured seeking the demonstration of the particular causative agent. In the meanwhile, as a preventive measure, it is believed that much may be gained by bettering the personal hygiene of the exposed workers. Thorough cleansing of the hands and forearms regularly should be obtained, possibly making use of disinfecting solutions. After thorough cleansing with or without resort to disinfectants, nonirritating emollients should be applied to the skin. Prior to undertaking work and for the purpose of lessening the cutting action of mica particles, something may be gained by the application to the hands and forearms of workers small quantities of hydrous wool fat. Carbolyzed lanolin may prove to be superior to the unmedicated variety.

These lesions are initiated by mechanical action of fine mineral particles into which there is a secondary invasion of either pyogenic or mycotic organisms.

PROTEIN PRODUCTS AND VASCULAR SPASM

To the Editor—What products of protein decomposition cause vascular spasm? What products of protein decomposition cause vascular dilation? Please omit name.

M D Connecticut

ANSWER—There is no specific product of protein that is known to cause spasm of the blood vessels. Excessive vasoconstriction of the peripheral vessels is seen in the course of some infectious diseases. Intravenous injection of foreign protein with production of a chill and fever, may be followed by constrictive effects during the period of chill. This vasomotor reaction is not specific but is simply a part of the mechanism of the chill and fever reaction. The most common basis of spasm of the small blood vessels is a hyperreactive sympathetic vasomotor mechanism. The vasomotor centers overreact to different stimuli. This constitutional form of vasoconstriction is believed to be present in Raynaud's disease. An opposing view is that there is some abnormality in the smaller vessels. There is a large group of secondary forms of vasospasm that are seen in the course of other conditions such as neuritis, organic disease of the blood vessels and poisoning by heavy metals such forms may be present also after disuse of an extremity or after trauma. In these recognized forms of abnormal vasoconstriction there is no reason to believe any protein is responsible.

Protein products may cause vasodilatation. Tissue extracts prepared from skeletal muscle, pancreas and heart muscle, when injected into the body, cause some degree of peripheral and general vasodilatation. There is widespread distribution of choline, which has vasodepressor effects, in tissues of the body. Histamine, an amine, may be found whenever protein is broken down into its amino acids, in the presence of putrefactive organisms. It is thus found in the intestinal tract and also in the tissues of the body. Histamine, or substances closely allied to it, may be released from the skin of certain subjects by cold. This may produce edema of the skin and typical systemic vasodepressor effects similar to those seen after the injection of histamine.

POSSIBLE CYST OF OVARY

To the Editor—Mrs. C. C., aged 45 was operated on when she was in her late twenties. The nature of the operation she does not know except that her ovaries were removed and that she has not menstruated since she was about 30. This is the best information she can give. Before the operation she gave normal (?) birth to one child who is still alive. In 1934 she slipped on an icy pavement, injuring her left side. She was dizzy following the fall had severe pain in the left utero-ovarian region and was confined to bed for six weeks. One month after the fall she had a profuse flow of blood from the vagina which lasted for one day and has not recurred. At present there is felt a mass about the size of an orange in the left ovarian region. The nature of the mass has not been determined. The woman feels fairly well and has gained weight. Hypothetically it is possible that she sustained a hematoma in the left pelvic region following the fall that some of the blood escaped through the vagina a month later, and that an organized clot is still present in that side? Kindly omit name. M D New York

ANSWER—The information concerning this case is incomplete. The statement is made that the patient was operated on when she was in her late twenties and an additional statement gives the information that the patient ceased menstruating when she was about 30 years of age. Presumably menstruation continued for a short time after the operation. If this is so, either both ovaries were not entirely removed or there existed some additional ovarian tissue outside the two ovaries.

While a hematoma in the left pelvic region may have resulted from the fall, it is hardly likely that this blood could have found its way into the vagina unless there existed a perforative injury on the left side of the vagina or the hematoma caused pressure necrosis at some point in the vagina. A more probable condition is a cyst of the remaining ovarian tissue. This cyst was most likely present before the accident. The latter may have resulted in injury to the cyst and in some way the mechanical insult to the cyst brought about bleeding from the uterus. The mass may be a special type of tumor of the remaining ovarian tissue. This group includes granulosa cell tumors, arrhenoblastomas, dysgerminomas and Brenner tumors. Some of these tumors induce bleeding in the uterus many years after the menstrual flow has ceased. In the presence of such tumors, no accident is necessary to bring about bleeding from the uterus. If the mass grows, bleeding recurs or there is pain and tenderness in the mass, it should be removed.

MIGRATING PHLEBITIS

To the Editor—I am treating a convalescent from lobar pneumonia and am quite puzzled by complications I have never seen before. She has multiple phlebitis over her entire body and all four extremities. She gives a history of having had the same thing about a year ago but at that time the phlebitis developed independently of any disease. She has an old myocarditis but no endocarditis as far I can make out.

D. STODDARD DOOMAN M.D. Garden City N. Y.

ANSWER—Migrating phlebitis is mostly regarded as a low-grade systemic infection, in which the intima of the vein is abnormally vulnerable or perhaps sensitized to a bacterial or toxic agent. The fact that the patient had multiple thromboses once before and has had a recurrence after pneumonia permits the assumption that the recent infection has acted as a sensitizer or reactivator of a slumbering process. Pneumonia per se is sometimes followed by thrombosis, as changes in the composition of the blood, such as increase in fibrinogen, produce a tendency to clotting of the blood.

The treatment is not very satisfactory. The disease runs its course and may end in a bland obliteration of the affected segments or may involve other segments and produce emboli. Every effort should be made to recover the organism from the blood stream or from an excised thrombotic vein so that a vaccine can be prepared. Minimal doses of this vaccine should be given so as to avoid general reactions or chills. In the absence of a specific vaccine triple typhoid vaccine may be administered cautiously from 100,000 to 1,000,000 bacteria being given intravenously, twice a week. Intravenous antiseptics have been advocated from time to time, more recently gentian violet.

Perhaps the best and certainly harmless is 40 per cent solution of methenamine, which can be given in 5 to 10 cc. doses daily. Needless to say, a satisfactory water intake and the maintenance of vitamin and mineral balance are important.

DERMATITIS

To the Editor—A woman, aged 43 complained of severe itching of the face and neck, with some redness of the face and neck and swelling of the face. There was large vesiculation with breaking of the vesicles. The rash extended to the chest and the back of the neck. The skin was flushed and there was a maculopapular type of rash with some small area on the neck which formed scaly patches almost like a crust. There was a maculopapular rash on the flexor surface of the lower arms and papules closely grouped on the dorsal surface of several of her fingers on the second phalanx. The rash is a dusky pink. The patient has been upset and nervous since the rash appeared and cannot sleep well because of the itching and burning. Scratching seems to bring out more papules which are light pink or the color of the skin. She has developed several boils on the back of the neck and in the axilla. Can you suggest a diagnosis from this history? Please omit name. M D, Alabama

ANSWER—The description suggests a dermatitis from some external contact. Does the patient have any house plants or has she handled paints or insect powder lately? All contacts, and there are many possibilities, should be investigated. Patch tests of cosmetics, cooking materials, feathers in pillows, and so on may be made, a small amount of the suspected material being placed on the uninvolved skin under a piece of oiled paper or gutta percha, fastened with adhesive plaster, and allowed to remain two days, provided itching does not occur in less time than that. If a dermatitis develops under any patch in two days or less this substance should be retested and, if again found positive, removed from the environment.

Scratching must be prevented, best by giving an antipruritic lotion to apply when itching occurs. Solution of aluminum acetate, 1 to 10, in cool water, as thin wet dressings alternating with calamine lotion with 0.5 per cent phenol are as good as any, but the patient's choice should determine the treatment as a rule. For the nervousness, bromides may be given by mouth or intravenously. The treatment of such cases is often difficult, as is the determination of the exciting cause.

The boils were secondary to the dermatitis, which caused a *locus minoris resistentiae*.

SILICOSIS NOT A SERIOUS HAZARD IN CAST IRON FOUNDRY

To the Editor—I have been doing the insurance work for a cast iron foundry for several years and would appreciate any information that you might give me regarding the danger of silicosis in men engaged in cleaning and polishing castings. After the castings are made they are put in a revolving machine called a rattler, to shake the excess sand and loose iron from the surface. They are then polished on emery wheels. How much danger is there of silicosis developing in men who have done this work for years and what would be the best way of keeping down this dust? Would early silicosis show on x-ray plates? Please omit name. M D, Virginia.

ANSWER—There is no reason why men engaged in cleaning castings and in tending machinery used for this purpose should be subjected to silicosis-producing dusts in harmful concentrations. Prevention of dust inhalation is an accomplished fact in many well conducted foundries, and improper conditions can be corrected by wholly practical devices (McConnell, W. J., and Fehnel, J. W. *J. Indust. Hyg.* 16:227 [July] 1934; McCord, C. P. Pamphlet published in 1932 by the National Foundry Association, Chicago).

Cleansing sand from castings by sand blasting or shot blasting is a recognized silicosis hazard entirely avoidable with modern equipment. Chipping off burrs and irregularities from sandy castings is likewise a practice that may cause silicosis and is readily avoidable.

The polishing of sand-free castings on emery wheels is standard foundry practice. The wheels gradually wear down, so that some finely divided abrasive and some iron dusts are thrown into the air. Neither of these dusts alone has been shown to cause silicosis. Information from the Norton Company, Worcester, Mass., is available on the design of dust exhausts for use with artificial abrasive wheels of all types. Such exhausts improve the working conditions.

Undoubtedly there is a silicosis hazard in the foundry that is conducted carelessly. At present the only method available for diagnosing early silicosis is by x-rays, and the foundry industry, like any other industry with a possible silicosis risk, should require periodic roentgen examinations of men with suspected dust exposure (Gardner, L. U. *The Pathologic Reaction in Various Pneumoconioses*, *THE JOURNAL*, Aug. 19, 1933, p. 594; Pancoast, H. K., and Pendergrass, E. P. *Roentgen Technic with Especial Reference to Examination of Diaphragm or Exclude Silicosis*, *J. Indust. Hyg.* 16:165 [May] 1934).

SINUS ON BRIDGE OF NOSE

To the Editor—A boy aged 12 years has a discharging sinus on the bridge of the nose it has been present since birth. At times no drainage will occur for days or weeks, then the nose and forehead will swell markedly over the base of the nose and inner half of each supra-orbital region. If the swelling is opened or allowed to open spontaneously pus and mucus drainage occurs and the swelling disappears. Then for days or weeks a slight drainage is present. During the time of drainage no other symptoms are present. I have tried injecting the sinus with Beck's paste and roentgenographing but I get a poor outline of the tract. The damming up caused by the paste causes swelling, headache, some fever and general toxemia. I thought the paste might aid in the healing process. Branchial cleft and dermoid cyst with sinus occur to me as likely diagnoses.

B B PARKER MD ALLERTON IOWA

ANSWER—The condition described is obviously rare. These fistulas have their openings high, as a rule, and may be followed downward to the lower end of the nasal bone or farther. They end nearly always blindly, not communicating with the nasal cavity. They may be classified as primary or secondary and when secondary usually are due to opening by a physician or to the spontaneous bursting of a dermoid cyst. The primary fistulas cannot be easily explained. One authority believes that the most likely cause is the improper closure during fetal life of the median nasal cleft, with possibly the capture of some amniotic membrane.

As to further diagnostic efforts, one might inject oil diluted one half with olive oil to avoid reaction and follow by roentgen examination.

Treatment rests between surgical extirpation and the use of some sclerosing preparation, as a modified Carnoy's solution (Cutler, E C, and Zollinger, R. M. Use of Sclerosing Solutions in Treatment of Cysts and Fistulas, *Am J Surg* 19 411 [March] 1933). Surgical removal would have to be complete. A small remnant of the tract left behind would in all likelihood cause a recurrence of the fistula. The use of a solution, as suggested, would probably be followed by painful reactions and would have to be repeated more than once and with proper safeguards.

BURSITIS

To the Editor—A man, aged 55 whose weight was between 233 and 240 pounds (106 and 109 Kg.) blood pressure 168 systolic, 90 diastolic, and urine examination always normal had negative past history except for rheumatic pains. Aug 25 1934 he struck his knee against an icebox and did not think much of the injury at the time although the knee felt sore and he lumped. September 5 he complained of pain in the knee and in various joints. He was given large doses of sodium salicylate and a bandage was applied to the knee which contained no fluid at that time. The patient continued to work in a store. October 18 20 cc. of syrupy fluid was withdrawn from the bursa under the quadriceps tendon above the patella. This was not connected with the knee joint. November 17 25 cc of the thick fluid was aspirated. November 19, 25 cc. was aspirated and the knee was put in a plaster cast. The cast was removed December 20 and 15 cc of fluid was aspirated and the cast reapplied. The fluid was aspirated Jan 8 and 18 1935. Following the last aspiration no fluid appeared and the knee felt well until February 28 when 25 cc of the thick fluid was aspirated and about 10 cc of salt solution injected. The knee was then tightly bandaged and the patient was told to remain in bed. He has not worked since early November. I have been anxious to inject the cavity which has been shut off from connection with the joint but have been advised not to taking the last aspiration when the salt solution was injected as my own tryout. A surgeon advised against removal of the sac. Please omit name.

M D New Jersey

ANSWER.—The case in question is classed as synovitis of the bursa, or bursitis.

It is probable that surgery including synovectomy or bursotomy, will be necessary but before this procedure is carried out the elements of trauma, infection and allergy should be investigated as thoroughly as possible otherwise recurrence might follow.

REMOVAL OF SILVER DEPOSITS FROM SKIN

To the Editor—In THE JOURNAL, May 11 page 1771 is a query from a doctor in Massachusetts about silver deposits on the skin. From the answer I judge that it was assumed that the deposit was below the epidermis. It is perfectly easy to remove superficial silver deposits by soaking the hands in a mixture of equal volumes of 25 per cent sodium hyposulphite (the ordinary hypo) and 10 per cent potassium ferricyanide. This is Farmer's reducer used in photography and is safer than the other effective mixture which is tincture of iodine followed by a dilute solution of potassium cyanide. The latter is dangerous except in the hands of experts who know enough not to dip their fingers into potassium cyanide if there are any cracks on them. Ordinary tincture of iodine is satisfactory and a 5 per cent cyanide solution is strong enough and will remove the silver iodide produced by the action of the iodine on the silver sulphide.

FRANCIS CARTER WOOD MD New York.

Medical Examinations and Licensure

COMING EXAMINATIONS

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY Written examination and review of case histories of Group B applicants will be held in various cities of the United States and Canada Dec. 7. Applications must be filed not later than Nov 1. Sec. Dr Paul Titus 1015 Highland Bldg Pittsburgh (6).

AMERICAN BOARD OF OPHTHALMOLOGY The Cincinnati examination previously announced will not be held. The next examination will be given in St. Louis Nov. 18. Application must be filed before Sept 15. Sec. Dr William H Wilder 122 S Michigan Ave., Chicago.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY St. Louis Jan. Sec. Dr Fremont A Chandler 180 N Michigan Ave. Chicago.

AMERICAN BOARD OF OTOLARYNGOLOGY Cincinnati Sept 14. Sec. Dr W P Wherry, 1500 Medical Arts Bldg Omaha.

AMERICAN BOARD OF PEDIATRICS Philadelphia Oct. 10 and St. Louis Nov 20. Sec. Dr C A Aldrich 723 Elm St., Winnetka Ill.

AMERICAN BOARD OF RADIOLOGY Detroit Dec. 12. Sec. Dr Byrl R Kirklin, Mayo Clinic Rochester Minn.

ARIZONA Basic Science Tucson Sept 17. Sec. Dr Robert L Nugent, Science Hall University of Arizona Tucson. Medical Phoenix Oct 12. Sec. Dr J H Patterson 826 Security Bldg Phoenix.

CALIFORNIA Sacramento Oct 21 24. Sec. Dr Charles B Pinkham 420 State Office Bldg Sacramento.

COLORADO Denver Oct 1. Sec. Dr Harvey W Snyder 422 State Office Bldg, Denver.

GEORGIA Atlanta Oct. 8-9. Joint Secretary State Examining Boards Mr R C Coleman 111 State Capitol Atlanta.

IDAHO Boise Oct 1. Commissioner of Law Enforcement, Hon Emmitt Pfost, 205 State House Boise.

ILLINOIS Chicago, Oct 22 24. Act Supt. of Regis Dept of Regis and Edu Mr Clinton P Bliss Springfield.

MICHIGAN Lansing Oct 8. Sec. Board of Registration in Medicine Dr J Earl McIntyre 202 3-4 Hollister Bldg Lansing.

MINNESOTA Basic Science Minneapolis Oct 12. Sec. Dr J C McKinley, 126 Millard Hall University of Minnesota, Minneapolis. Medical Minneapolis Oct 15 17. Sec. Dr Julian F Du Bois 350 St Peter St St. Paul.

MONTANA Helena Oct 1. Sec. Dr S A. Cooney 7 W 6th Ave. Helena.

NATIONAL BOARD OF MEDICAL EXAMINERS The examination will be held in all centers where there are Class A medical schools and five or more candidates desiring to take the examination, Sept. 16-18. Ex Sec. Mr Everett S Elwood 225 S 15th St Philadelphia.

NEW HAMPSHIRE Concord Sept. 12 13. Sec. Board of Registration in Medicine Dr Charles Duncan State House Concord.

NEW JERSEY Trenton, Oct. 15 16. Sec. Dr Arthur W Belting 28 W State St Trenton.

NEW MEXICO Santa Fe Oct. 14. Sec. Dr Le Grand Ward Sena Plaza Santa Fe.

NEW YORK Albany Buffalo New York and Syracuse Sept. 16 19. Chief Professional Examinations Bureau Mr Herbert J Hamilton 315 Education Bldg Albany.

RHODE ISLAND Providence Oct 3-4. Dir. Department of Public Health Dr Edward A McLaughlin 319 State Office Bldg Providence.

WISCONSIN Basic Science Madison Sept 21. Sec. Professor Robert N Bauer 3414 W Wisconsin Ave Milwaukee.

WYOMING Cheyenne Oct. 7. Sec. Dr G M Anderson Capitol Bldg Cheyenne.

Mississippi June Report

Dr Felix J Underwood, executive officer, Mississippi State Board of Health, reports the written examination held in Jackson, June 25-26, 1935. The examination covered 12 subjects and included 96 questions. An average of 75 per cent was required to pass. Thirty-one candidates were examined, 30 of whom passed and 1 failed. Ten physicians were licensed by reciprocity and 1 physician was licensed by endorsement. The following schools were represented:

School	PASSED	Year Grad (1935)	Per Cent	Reciprocity with
Emory University School of Medicine	811 86 861 867	(1935)	81	
Louisiana State University Medical Center		(1935)	82.8*	Georgia

Book Notices

The Treatment of Fractures. By Dr Lorenz Böhler, Director of the Hospital for Accidents Vienna. Fourth English edition translated from the fourth German edition by Ernest W Hey Groves, M.S. M.D. F.R.C.S. Consulting Surgeon Bristol General Hospital. Cloth. Price \$12. Pp 578 with 1 059 illustrations. Baltimore: William Wood & Company 1935.

Previous editions of this book in German and French have been reviewed in THE JOURNAL. The qualifications of the author are excellent. Hey Groves, the translator, has contributed much to the principles and practice of the treatment of fractures. Few books on the subject have presented the material as clearly and concisely as this one. Almost none have had the large number of beautiful and instructive illustrations. The book represents the outcome of the experience of nineteen years of treatment of more than 10,000 cases of fractures, the study of about 70,000 roentgenograms and the dissection of more than 300 fractures of the long bones chiefly during the war. The author has treated fractures under the most diverse conditions. The results of the treatment of fractures depend not merely on the use of certain appliances and methods but even more largely on the education of the surgeon and the organization of the clinic. The fundamental principles demonstrated by Böhler are the necessity for unity of control, loyal and efficient team work, accurate knowledge of the after-results and meticulous attention to details. Böhler has demonstrated that the proper treatment of fractures is not only a scientific problem and philanthropic duty but also a business proposition. The translator states that "it pays" to treat fractures well. The new material in the English edition deals with the anatomic conditions and the treatment of fractures and fracture-dislocations of the cervical spine that have been revised in the light of recent experience. The section on the calcaneus has been thoroughly revised, as a follow up of the cases has shown that reduction by the Phelps-Gocht clamp with tenotomy of the achilles tendon has not given good results owing to the recurrence of displacement. There is a section dealing with "mistakes," which has been elaborated for each type of fracture because it is possible to avoid these only by studying the mistakes already made by

others, and some of the procedures that Böhler formerly advised he now relegates to the category of "mistakes." It would require too lengthy a review to go into details concerning the treatment of particular fractures. The reader will be well repaid for reading this book. One can easily understand why Vienna is a mecca for young and old practitioners and students of the art and science of the treatment of fractures. When the history of fractures is written, Böhler's name will appear prominently, establishing a Böhler era or milestone. This book will rank high with all traumatic, orthopedic and general surgeons.

Emotions and Bodily Changes. A Survey of Literature on Psychosomatic Interrelationships 1910-1933. By H Flanders Dunbar, M.D. Ph.D. Departments of Medicine and Psychiatry, Columbia University. Published for the Josiah Macy Jr. Foundation. Cloth. Price \$5. Pp. 595. New York: Columbia University Press, 1935.

The relationship of the body to the mind and vice versa has been the subject of much study by the psychiatric, psychoanalytic and medical groups. The present volume is an attempt to bring together some of the vast research material that has been reported in the literature. Of the author's ideas concerning the mind-body relationship there is little direct information, for the book is a systematic collection of abstracts, rather than a thesis, concerning the problem at hand. It is possible, however, to perceive that the author agrees with leading psychiatrists and psychoanalysts that much can be done with the so-called physical disorders by means of psychologic treatment and that such treatment is as "scientific" as any other medical therapeutics. On the other hand, many psychologic symptoms are conceded to rest on a physical basis. In the first of the three sections of the book the development of mind-body theories is brought out, including an excellent discussion (by means of abstracts of articles) of methods of measuring the emotions. Part II takes up the changes in the nervous, respiratory and cardiac systems due to emotional action and interaction, stress being placed on metabolism. The third part comprises a short section on therapy. The final quarter of the book consists of a thorough bibliography. There are many items in the bibliography that are merely mentioned in the text of the book. The bibliography is of as much value to the student as the main part of the book. The present work should be stimulating to any one who wishes to orient himself in the psychologic aspect of disease. With psychoanalysts relieving sufferers from gastric ulcer and psychiatrists furnishing some of the theory for treating asthma and functional heart disease, the author's point is well taken when she says "Psychiatry is finding its place within medicine on the same basis as any other specialty" and "Psyche and soma are actually two aspects of a fundamental unity." The volume gives evidence of much insight, brilliance and extensive research into the literature and may well serve as a crystallizing influence in the field of mental medicine.

Handbuch der Ärztlichen Sachverständigen Tätigkeit. Herausgegeben von Professor Dr. Paul Dittlich. Band VI. Teil 2. Der Kindesmord in der Ärztlichen Sachverständigen Tätigkeit. Von Professor Dr. Paul Dittlich. Boards. Price 10 marks. Pp 118 with 50 illustrations. Berlin & Vienna: Urban & Schwarzenberg 1935.

This is the second part of the sixth volume of a handbook on the activities of physicians as experts, published with the assistance of the department of public health of the republic of Czechoslovakia. It deals with the medicolegal aspects of murder of the new-born. Full directions are given for the examination of new-born bodies under various conditions (thirty-five pages). The next section is devoted to the legal enactments concerning the crime in question in Austria, Germany and Czechoslovakia and to the determination of how long a dead infant may have lived after it was born. Then are considered the causes of death in the new-born—death before birth, death in the course of birth, natural death after birth, and violent death after birth. The other sections concern the kinds of murder of the new-born, intentional neglect and exposure of the new-born, and illustrative postmortem examinations with reports. The illustrations tell their story well. The presentation is clear, thorough, competent. It will be of service to the physician expert when he is required to aid the course of the law against taking the life of the new-born.

Diet Control A System of Eleven Hundred Diets for the Prescription of Diabetic, Anti Obesity and Measured Diets in General By George E. Anderson M.D. Attending Physician to the Brooklyn Hospital and Paul Chadbourn Eschweiler M.D., Assistant Attending Physician to the Brooklyn Hospital. Cloth Price \$3.50 Loose Leaf New York: Gallo & Ackerman Inc. 1934 1935

This contains twenty pamphlets, one of which is explanatory of the diabetic diet system employed by the authors while the remaining pamphlets are intended to be distributed to individual patients as diet prescriptions. This particular system is built on a "basic diet" (1,085 calories carbohydrate 100, protein 70, fat 45) which supports the principle of high carbohydrate-low fat diets generally advocated today and contains the minimum food essentials for optimum needs in the form of calcium, phosphorus, iron, protein, protective foods and vitamins. These are supplemented by additional carbohydrate, protein and fat units in accordance with a sliding scale of caloric values to meet the varying tolerance of the patients. Frankly, this is one of the most satisfactory schemes of diet that have been suggested. Its merits include a minimum of calculation and explanation on the part of the physician, while the patient is allowed a wide variety of food choice and the advantage of using common household measurements. Incidentally, the basic diet also serves as an antioesity regimen. The publication is primarily intended for patients in the Brooklyn Hospital, where the system originated and where instruction is given the patient during hospitalization, but it is worthy of the critical consideration of all physicians in the diabetic field.

Klinik und Therapie der Herzkrankheiten. Vorträge für praktische Ärzte Von Privatdozent Dr. D. Scherf, Assistent der I. medizinischen Universitätsklinik in Wien. Paper Price 6.80 marks. Pp 210 with 16 Illustrations. Vienna: Julius Springer 1935

This little volume of lectures for general practitioners deserves translation into English. It is replete with fundamental physiologic and clinical facts concerning the heart and the circulation. The introductory discussion of dyspnea and other symptoms and signs of cardiac insufficiency is a model of accuracy and lucidity. The diagnosis and differential diagnosis of the various types of heart disease are then treated briefly but exceedingly well. One regrets that, for lack of space, the author omitted discussion of congenital heart disease, pericarditis, bacterial endocarditis and the arrhythmias. The section on treatment is a store of clinical experience and wisdom, with one minor exception. This is a shot-gun mixture of all the known vasodilators and other substances, which the author administers to patients with angina pectoris. The chapter on digitalis therapy is admirable. Although the author has purposely omitted references to the literature, he has succeeded in bringing into his lectures all the recent contributions of worth in the field of cardiology. Physicians who study this book carefully will acquire a real enthusiasm for the diagnosis and treatment of their cardiac patients.

The Individual Criminal Studies in the Psychogenetics of Crime By Ben Karpman M.D. Psychotherapist St. Elizabeths Hospital Washington D.C. Volume I. Cases 1-5. Nervous and Mental Disease Monograph Series No. 59. Cloth. Price \$4.50 Pp 317. Washington D.C. The Nervous and Mental Disease Publishing Company 1935

This volume is an earnest bit of work consisting of a minute analysis of five criminal cases, all from St. Elizabeths Hospital, and hence all under the cloud of mental disease. The cases are each analyzed from the standpoint of the past experiences of the offender, and to the author's interpretation of factors concerned in the case he adds a second discussion consisting largely of a differential diagnosis. The cases are not typical either of the everyday offender or of the psychotic. They are borderline cases, diagnosed with difficulty and probably with some psychoneurotic substrata, a feature much overstressed by those who know psychiatry but not criminals. Each case is interesting because much of the "interpretive" part consists of a running life story. Nevertheless sociological documents such as the Jack Roller seem to be of more significance in revealing the mental mechanisms of criminals and the etiologic factors entering into them. At the end of each study is an analysis called a 'psychobiopsy' showing the author's opinion regarding salient features of the patient's life. There are three sections entitled 'crime mechanics,' dealing with crime in general apparently

written in part by an inmate revealing little that is new and in places showing much of the stereotype thinking of the chronic offender. Some of the author's dreams and other interpretations are valuable, but there are many statements of psychiatric definition and explanation that are extremely dubious. There is a section on criminal jargon that would only be in part recognized by the hardened offender. If one accepts this book not as a presentation and analysis of five nontypical offenders but as an expose of the problem of crime in relationship to psychology, it leaves something to be desired. It would perhaps be more convincing if the cases were selected from a prison, and if the details regarding the obtaining of rapport were presented. There are two vast maps inside the back cover, which are not of great value. The volume is apparently intended to be part of a bigger work and it may be that, integrated with a broader study, it could become a distinct contribution.

Monographien aus dem Gesamtgebiet der Physiologie der Pflanzen und der Tiere. Herausgegeben von M. Gildemeister R. Goldschmidt R. Kuhn J. Parnas W. Ruhland und K. Thomas. Band XXXIII. Der Wasserhaushalt des gesunden und kranken Menschen. Von Dr. Hellmut Marx. Privatdozent an der Universität Berlin. Paper Price 27 marks. Pp 335, with 52 Illustrations. Berlin: Julius Springer 1935

Marx has presented probably the most comprehensive consideration of water metabolism in health and disease that can be found anywhere. In the first chapter he discusses the property of water and its importance to the organism, in the second, the method employed in the studies of water metabolism, in the third, the role of various organs in water metabolism, in the fourth, water in relation to edema, in the fifth, water in relation to output, in the sixth, the regulation of the water balance of the body and the part played by the cerebral centers, the midbrain and the hormones, in the seventh, the physiology of thirst. The bibliography is excellent. From both the physiologic and the clinical point of view a wealth of material is presented. The volume should prove of interest and value to students of metabolism in the laboratory and the clinic. It will probably constitute a standing contribution to our knowledge of this subject.

Principles of Ethics. By Dom Thomas Verner Moore Ph.D. M.D., Director of the Clinic for Mental and Nervous Diseases, Providence Hospital, Washington D.C. Lippincott's Nursing Manuals. Cloth. Price \$3. Pp 381. Philadelphia and London: J.B. Lippincott Company 1935

This is based on a theistic philosophy covering a wide range of individual and social relationships. It gives a free interpretation of moral rather than medical ethics from the point of view of a selective group. It expounds the behavioristic as well as the debatable questions of contraception and abortion. Its greatest value is its use as a reference work rather than as a textbook in dealing with the daily problems of nurses. The standpoint toward craniotomy is one that will interest surgeons as well as obstetricians. The book throughout has an arousing interest in the old philosophers, especially the concluding chapters which are rather an abrupt departure from the preceding ones. The literary style is modern and lucid, making it easy to read instead of onerous, as are most books of this kind. The value of the volume lies in the clear exposition of deeply rooted theistic theories forming the framework and background of principles of ethics that influence moral and medical decisions of many people.

Studies on the Dissociation of the Dysentery Bacilli By Erik Waaler from the Bacteriological Laboratory of the Norwegian Army. Paper Price 18.50 kroner. Pp. 176 with 53 Illustrations. Oslo: Jacob Dybwad 1935

This monograph gives the results of a detailed study of the dissociation forms of twenty-six strains of dysentery bacilli, mostly of the Flexner and Sonne types. The variants are classified chiefly by their antigenic behavior. Much of the discussion is of too technical a character to appeal to any but special students of the dissociation problem. Two points of general interest may be mentioned. First, a new variant derived from R forms is described which produces no antibodies when injected into rabbits, it is designated as R₀. Second, the processes of dissociation in the strains studied by Waaler have taken place in one direction only from S to R and further to R₀, no antigenic reversion was observed.

The Method of Action of Radium and X Rays on Living Tissues By Hector A. Colwell M.B., Ph.D. M.R.C.P. Awarded the Garton Prize and Gold Medal of the British Empire Cancer Campaign 1934. Cloth Price \$5. Pp. 164 with 34 illustrations. New York & London: Oxford University Press 1935.

In this comparatively small volume the author deals with the various phases of radiation effects on living tissues, including biologic, serologic and histologic aspects of the problem. The first chapters are devoted to the effects of radiation on cells and their components, to the chemical action of radiation, and to the influence of radiation on the reticulo-endothelial system and on the immunity actions of the body. The most important chapters deal with the effects of radiation on tumor growth and on resistance to tumor growth, and the action of radiation on living tumors. It is impossible in a short review even to signify the full content of this fascinating book. Although the author has to discuss a number of special questions, he never loses the broad general biologic view. The book meets a need and not only is it a convenient guide for the experimental worker but it gives to the clinical radiologist who wishes to administer his treatments with an intelligent understanding a real scientific and critical basis. A short bibliography is appended.

The Newcastle upon Tyne School of Medicine 1834-1934 By G. Grey Turner. Assisted by W. D. Arncliffe. Cloth Price 10/-. Pp. 224 with 50 illustrations. Newcastle upon Tyne: Andrew Reid & Company Ltd. 1934.

On the one hundredth year of its founding, the authors attempt to give a chronological account of the history of this famous school, which changed both name and habitation often. In doing so the authors admittedly rely heavily on "The History of the Medical School," published forty years ago by Dennis Embleton. However, many new additions are said to have been made by a great number of credited contributors. An introductory poem by Maurice Jacobs recounts some of the illustrious men of the faculty, not least of whom is Murray, who first successfully treated myxedema by means of thyroid. Throughout the volume are short biographic sketches of the various teachers in the medical school during the past hundred years as well as the names of some of the students. One of the latter, John Snow (p. 20), deserves more mention than allotted him, for he was not only himself "a skilled chloroformist" and etherist but it was he who put the administration of both chloroform and ether on a truly scientific basis.

Introduction to Psychology with Special Applications to Nursing and Nursing Problems By Edward S. Robinson. Professor of Psychology Yale University and Virginia Kirk, Director of Nursing Emma Pendleton Bradley Home East Providence R. I. Cloth Price \$2.50. Pp. 368, with 55 illustrations. New York: Macmillan Company 1935.

Most of the material of this book is taken from the senior author's Readings in Psychology and put in more popular style for consumption by nurses. The work is not intended for physicians or specialists. As a textbook for nurses it seems to assume too great an academic point of view. The academic psychologist as evidenced by this and other works seems far removed from the living human being with his complicated emotional life and environmental stresses. To the extent to which this is true, the volume fails to meet the real needs of the nurse. It has, however, a fairly elementary and readable summary of current psychologic data.

A Brief Outline of Modern Treatment of Fractures By H. Waldo Spiers, A.B. M.D. Professor of Orthopaedic and Fracture Surgery College of Medical Evangelists, Los Angeles, California. Cloth Price \$2. Pp. 129 with 109 illustrations. Baltimore: William Wood & Company 1935.

In this outline the author aims to touch only the high spots and their practical application. He discusses briefly some of the more recent accepted methods of treatment and presents the fundamental principles of fracture surgery. All the illustrations are line drawings and most of them are instructive. The secret in the treatment of many cases that appear to present delayed union is to give the reparative process more time. The author states that in one's haste to do things in new and radical ways one gets patients out of the hospital and on their feet and may not immobilize sufficiently. He outlines the factors that contribute to nonunion as failure to immobilize, interposition of soft tissue, ill advised operative procedure, insufficient circulation, dietary

deficiency and certain diseases. The fundamentals of the surgical treatment of nonunion are removal of scar, both soft tissue and bony, freshening of the ends of the fragments, fixation of the fragments—internal, external or both, and stimulation of bone regeneration by grafts, osteoperiosteal grafts or multiple drilling. He advises the surgeon to roentgenograph all fractures after reduction and to retain the films himself, to roentgenograph all suspicious injuries, to be prepared to release easily and quickly all constricting circular casts or bandages on an extremity, to protect the fracture until union is firm, to take the responsibility seriously and, if in difficulty, to call skilled consultation early. Brief criticism is justified as follows: Figure 67 was undoubtedly taken from G. G. Davis's Applied Anatomy and figure 97 from R. Watson Jones without due credit being given. All in all, it is a satisfactory book for the medical student.

Miscellany

ANTEPARTUM GROUP INSTRUCTION

RICHARD A. BOLT, M.D., DR.P.H.
Director Cleveland Child Health Association
AND
ELLA GEIB
Secretary to Director
CLEVELAND

Antepartum group instruction in Cleveland was initiated in 1922 by Mrs. Ellen D. Nicely, R.N., Nurse Director of Clinics, in the University Public Health Nursing District. The time of groups of mothers, awaiting their turn to interview the doctor in the clinic, was occupied in listening to the nurse as she explained in simple language matters of hygiene, nutrition, clothing and infant care.

The program was developed further under the Cleveland Health Council, and when its value had been demonstrated it was taken over by Maternity Hospital in 1929. This made possible the extension of group instruction in the eight maternity dispensaries throughout the city and in three other hospital clinics. Owing to contraction of funds in 1932, the Maternity Hospital was unable to continue the program. It then came under the direction of the Cleveland Child Health Association, which raised special funds for this purpose. The service was expanded and a second nurse was employed to assist in the program.

TO WHOM SERVICE IS OFFERED

The lectures now are open to any woman in Greater Cleveland who wishes to avail herself of the advantages of the classes. Until 1932 the lectures were given only to "clinic" or "free" patients and were conducted in hospital clinics. During 1932 an experimental class for the patients of private physicians was started in the Academy of Medicine of Cleveland. This proved so successful that several more classes for the patients of private physicians have been opened.

HOW PATIENTS ARE RECRUITED

Contact with clinic patients is made in hospital obstetric clinics on antepartum clinic days. The class usually precedes examination by the physician. Mothers coming to these clinics automatically attend the antepartum classes.

Patients of private physicians are instructed in classes separate from clinic patients. These are located in the Academy of Medicine of Cleveland, hospitals, recreation centers, and branch stations of the Visiting Nurse Association. Patients come to the classes through reference of their own physician, recommendation of former patients who have attended the classes, and occasional newspaper publicity. Recently detailed plans were agreed on by the Academy of Medicine of Cleve-

land and the Cleveland Child Health Association for the acceptance of patients in classes for private physicians. A copy of the agreement is given at the end of this article.

OUTLINE OF LECTURES

Eight lectures comprise each course. As soon as one series is completed, another is begun, so that patients may start on any lecture and continue until they have all eight lectures. Patients may repeat lectures if they so desire, and a number of mothers avail themselves of this opportunity. An attractive mimeographed outline accompanies each talk, topics of which are

- 1 Responsibilities of Motherhood and Importance of Medical Examination
Poster demonstration of growth and development of the baby
- 2 Personal Hygiene and Proper Dressing
Demonstration of corsets and binders
Demonstration of correct positions for sitting and resting in bed to bring about the greatest comfort
Discussion of sleep exercise elimination weight teeth and clothing
- 3 Diet of Expectant Mother
Poster demonstration of foods and menus
Graphic demonstration showing needed quantities of essential minerals
- 4 The Layette
Demonstration of complete baby outfit.
Advice on what is essential together with information on where the items may be purchased and current prices of each
- 5 Preparations for Delivery
Discussion of last ten days of pregnancy and first six weeks after the baby is born
Demonstration of preparation of bed for home delivery given in clinic classes
- 6 Habit Formation
Sleeping eating bathing, and elimination habits for baby discussed
Demonstration of care of diaper and use of chamber and training panties
- 7 Emotions
Fears anger, jealousy imagination play and playthings.
- 8 Hygiene of Nursing Mother and Care of the Baby
Demonstration of breast and abdominal supports
Demonstration of use of baby's tray
Demonstration of how to nurse the baby
Demonstrations of baby's bath are given to mothers before they leave the hospital. Only when requested are they given in the classes

TEACHING TECHNIQUES

Approach to the mother in the classes for private physicians is somewhat different from that for clinic patients because, as a rule, the former have a better educational background. In clinics the class usually lasts half an hour, but it may be extended if the physician is not ready for the patients at the end of that time. Lecture topics change every two weeks.

As the expectant mothers who attend classes for patients of private physicians meet specifically for the lecture period, it is possible to add more to these classes. Here the lecture period is fifty minutes, followed by a ten-minute discussion. The topics change weekly. These patients are given postcards to be mailed to the United States Children's Bureau, requesting the following pamphlets on antepartum and child care for further study

Prenatal Care
Infant Care
The Child From One to Six
Child Care
Child Management
Are You Training Your Child To Be Happy?

MOTHERCRAFT CLASSES

In addition to the lectures mothercraft classes are held in which the women are taught to make practical layettes. Materials are purchased in large lots at wholesale prices, and the garments are cut out prior to the classes. These are sold to the mothers at cost. Instruction includes all sewing stitches, simple crocheting and embroidering. Articles that are being made in the classes include nightgowns, kimonos, pantie style diapers nainsook dresses, nainsook slips, gertrudes, saques,

bonnets, booties, blankets, towels and wash cloths, baby bunnings, carriage robes, lap protectors and bath aprons. Many of the prospective mothers secure the entire layette in this way.

PERSONAL CONFERENCES

When a mother appears to have some special problem, the instructors arrange a time for a personal conference. Often the question is one that may be covered in a subsequent lecture. Sometimes fears or superstitions have been implanted in the woman's mind. Many do not understand the value of the doctor's examination. Sometimes the mother is troubled about something and is afraid or too timid to consult her doctor. In the latter cases the instructor tries to put the woman in the frame of mind to consult her physician, and, when she deems it advisable, the nurse telephones the physician to let him know the circumstances revealed to her so that he is prepared to help the patient on her next visit. The great value of these conferences is that they ease the mind of the expectant mother, giving her a clearer picture of what has been vague.

VISITS TO PATIENTS

It is impossible for the instructors to visit all the women who attend the classes. As information regarding delivery and postpartum care of clinic patients can be obtained from the clinic records, only such cases presenting special difficulties are visited. However, an attempt is made to visit the greater number of the patients of private physicians who are delivered in the hospitals. These visits usually are made on the days in which the instructor is at the hospital for a clinic class. In the case of some complication, such as a mental condition or an abnormal baby, a home visit may be made.

CALLS ON PHYSICIANS

When a physician is informed that his patients are attending the lectures, or when he first contemplates referring his patients to the classes, he often requests an interview with the instructor to learn exactly what instruction is given. The instructor then visits the physician on appointment in his office to explain the work. This usually clears up any misunderstanding and secures his hearty cooperation.

STUDENT INSTRUCTION

Students in the University Public Health Nursing District Teaching Center attend at least one lecture for observation. This provision applies to students in all Cleveland hospitals affiliating with the teaching district, who are taking two months' public health work in the district.

As an introduction to the antepartum project, postgraduate nurses from the School of Applied Social Sciences of Western Reserve University are given two group lectures by the antepartum instructors. With the help of the instructor in preparing lecture outlines, each student then teaches two of the clinic classes, a report of which is made to the teaching district.

TALKS TO SPECIAL GROUPS

On request, the antepartum instructors give lectures to outside groups, such as parent-teacher associations and church societies. Talks have been given to the clerks in the infant departments of the larger stores in order to give them a better understanding of what garments to suggest to the customer who is trying to select a suitable layette.

RECORDS

The patient of a private physician must present an admission card signed by her physician before she is registered in the class. These cards, which contain space for the patient's name and address, the physician's signature and the date issued, are furnished to physicians by the Academy of Medicine.

When an expectant mother enrolls in the class she is registered in an attendance book, with the following information

- | | |
|------------------------|--|
| 1. Registration number | 7. Month delivery is expected |
| 2. Name of mother | 8. Name of physician (unless a clinic case) |
| 3. Address | 9. Columns in which to list dates of attendance. |
| 4. Color | |
| 5. Parity | |
| 6. Age. | |

After the mother has been confined, the following information is added to the records

1. Date of delivery
2. Home or hospital delivery
3. Any complications in delivery or deformities of the new born infant
4. Deaths of mothers or infants, with causes

This information is secured from clinic or hospital records in the case of clinic patients. Patients of private physicians are furnished follow-up cards containing space for this information, in return envelopes, to be mailed to the Child Health Association office after delivery. This may be supplemented by hospital, physician, or Division of Health records when necessary. In this way a complete record is kept of each mother.

On receipt of the card from the mother announcing the arrival of the baby, a congratulatory card signed by the instructor is mailed to the mother from the office of the Child Health Association.

PERSONNEL

Qualifications necessary for the successful instruction of expectant mothers are many. A thorough training in public health nursing, with special emphasis on the hygiene of maternity and infancy, is the foundation. The instructor must acquire a knowledge of social hygiene, child psychology and nutrition, as these play important roles in maternal care. She should be versed in teaching methods, in public speaking, and in group and individual psychology. If mothercraft classes are included in the program, she must have a teaching knowledge of sewing.

She should know the regulations of the health department and the local hospitals and the preferences of the local obstetricians. She must keep abreast of new developments in her line. She should keep informed of what maternity and infant garments and equipment are on the market in order to advise mothers in making suitable selections. Above all, she must possess a personality that will secure the confidence of both the expectant mother and her physician.

COST OF PROGRAM

In considering the establishment of an antepartum group instruction program, finances must be considered. Necessary funds for the salaries of capable instructors must be provided. There is the initial cost of setting up the demonstrations for the lectures. In Cleveland the space, heat and janitor services for the classes are furnished by the organizations operating the buildings in which the classes are held. To carry the demonstrations satisfactorily and to get quickly from one class to another, it is advisable that the instructor drive a car, which means transportation expenses. Current expenses for stationery and other supplies also should be included. A part of this expense may be met by charging a nominal admission fee of patients of private physicians and by selling at cost the outlines and materials used in the classes.

SERVICE FIGURES

During 1934, lecture classes in Cleveland for clinic patients were held in four locations and for patients of private physicians in four locations, 646 classes were held, 2,305 individuals registered in the classes, with a total attendance of 12,785. The maternal mortality rate of women attending these classes in 1934 was 1.4 per thousand live births, compared with the city rate of 5.2. If deaths from abortions are eliminated, the city rate for 1934 was approximately 4 per thousand live births.

AGREEMENT BETWEEN CLEVELAND CHILD HEALTH ASSOCIATION AND ACADEMY OF MEDICINE

Following is a copy of the plan agreed on for the conduct of the lectures presented by the Cleveland Child Health Association and the Academy of Medicine of Cleveland.

1 The Academy of Medicine of Cleveland recognizes the value of the lectures on prenatal care and feels that they meet a definite need and that they should be continued.

2 The joint sponsorship of the lectures for patients of private physicians by the Cleveland Child Health Association and the Academy of Medicine of Cleveland is entirely satisfactory and there is no criticism of the lectures as conducted or of any individual associated with their presentation.

3 In order to assist in meeting the expenses of presenting these lectures, each applicant shall be charged the sum of one dollar for the course of eight lectures. The fee shall be elastic and may be waived in case the patient shall be unable to pay. The inability to pay the fee shall be decided by the physician referring the case or by the nurse in charge of the lecture, after investigation.

4 The fee shall be collected from the patient by the nurse in charge of the lecture and an account shall be rendered to the Academy of Medicine of all such money collected. All funds collected shall be applied by the Cleveland Child Health Association to meeting expenses incident to the presentation of the lectures.

5 No patient shall be accepted at the lectures without the consent of her physician.

6 No patient shall be admitted to the lectures except upon the presentation of an admission card supplied to her physician by the Academy of Medicine of Cleveland, which admission card is herein described.

7 In the case of a patient applying for admission to the lectures without first obtaining the reference of her physician, she shall be informed at once by the nurse in charge of the proper procedure for admission, but she may be permitted to attend that lecture at which she has first presented herself.

8 In case of such patients who present themselves without the reference of their physician the nurse in charge shall, in every case obtain from the patient the name and address of her physician and such patient shall be informed that the Academy of Medicine of Cleveland will communicate with her physician, explain to him the nature of the instruction given in the lectures, and, if he desires, furnish him with a proper admission card for his signature. This card may be sent to the office of the Academy of Medicine or it may be given to the patient to present at the next lecture.

9 In case the physician does not desire the admission of his patient to the lectures she may not be admitted and she shall be so informed by letter from the Academy of Medicine before the time of the next lecture.

10 The office of the Academy of Medicine of Cleveland shall communicate immediately with any physician whose patient presents herself at the lectures without his reference and shall explain to him the nature of instruction given in the lectures and shall tell such physician that his patient may be admitted only with his consent and if he then shall desire his patient to attend the lectures he shall be furnished with an admission card by which he may refer his patient to the lectures.

11 In case a patient attending the lectures without reference by a physician shall claim to have no physician and to know of none to whom she might go, such patient shall be referred by the nurse in charge to the office of the Academy of Medicine of Cleveland, which office shall, upon her application, furnish her with the names of three physicians of the type and in the location to fit her needs. No nurse shall at any time recommend a physician or refer a patient to one.

12 All the above provisions shall apply equally to physicians whether members or nonmembers of the Academy of Medicine of Cleveland.

13 There shall be designed and furnished to physicians who desire to refer patients to the lectures an admission card, which shall state that the lectures are conducted jointly by the Cleve

land Child Health Association and the Academy of Medicine of Cleveland, and shall contain a space for the patient's name and address and the physician's signature and the date issued. Such cards may be furnished only by the office of the Academy of Medicine of Cleveland to physicians.

14 There shall be no change in the procedure or method of supervision or in the conduct of the lectures except by joint approval of the Cleveland Child Health Association and the Academy of Medicine of Cleveland.

15 Nothing herein set forth shall apply to such lectures as are now conducted at certain of the hospitals of Cleveland
1900 Euclid Avenue.

Medicolegal

Compensation of Physicians Compensation for Medical Services Contingent on Recovery of Damages, Validity of Contract—Sophie Magid was injured through the negligence of a third person. The physician-plaintiff agreed to treat her and to accept as his compensation 20 per cent of any amount she might recover from the person responsible for her injuries. If she received nothing the physician was to obtain nothing. The patient thereafter started suit against the person responsible for her injuries but was reluctant to proceed. On the physician's insistence she proceeded to trial. At the trial the physician testified and procured another medical expert to testify, and the patient obtained a verdict for \$7,200. On the failure of the patient to pay the physician, he instituted this present action to recover 20 per cent of the \$7,200 verdict obtained by the patient. From a judgment for the patient, the physician appealed to the Supreme Judicial Court of Massachusetts.

The contract, said the Supreme Judicial Court entered into between the physician and the patient and the inference necessarily drawn therefrom, namely, that the physician would testify in behalf of the patient at a future trial, presents a case which has every element of an unlawful agreement. It contemplates legal proceedings it provides for a sharing in the fruits of litigation it is an agreement in which the physician had no previous interest in the subject matter of the litigation, and it provides that the fruit of the litigation contracted for shall be the only compensation the physician is to receive. Without invoking the rule governing such unlawful agreements continued the Supreme Judicial Court, it has been directly held that a contract by one injured to pay a percentage of the amount received from the one responsible for the injury to his physician for services in treating the injury is against public policy and void where the parties contemplated that the physician shall be a witness for his patient in case suit is necessary. The court accordingly affirmed the judgment of the trial court in favor of the patient.—*Venbergh v Magid (Mass)* 189 N E 110

Accident Insurance Trauma Inducing Spread of Quiescent Streptococcal Infection.—The defendant insurance company promised to pay certain benefits on the death of Lewis from bodily injuries effected directly and independently of all other causes by accidental means and due solely to external, violent and involuntary causes" resulting in continuous total disability from the date of the accident, but not for death due to disease, whether accidental or otherwise." Lewis, in diving June 15 struck his head on the bottom of a lake and fractured an infected tooth causing a generalized spread of the infection. Although complaining of dull head pains and extreme lassitude, and although having a temperature sometimes as high as 104 he continued at work until August 23, when he was taken to a hospital, where he died on August 29. His wife brought suit in the district court of the United States for the western district of Pennsylvania against the insurance company and recovered judgment. The insurance company appealed to the circuit court of appeals, third circuit, which at first affirmed the judgment of the district court but, on reargument reversed the judgment and ordered a new trial.

The insurance company contended that Lewis's death was not caused directly and independently of all other causes by accidental means, but by the dissemination of streptococci which were lodged in the roots of an abscessed tooth. To sustain its contention the insurance company cited a number of cases, which, in substance, held that no recovery may be had under a policy similar to the policy here in question if the death of the insured results from an aggravation of a preexisting disease and if the accident, alone, would not have caused the death. But, answered the circuit court of appeals, in all the cases cited the insured was not in normal health but was suffering from some well recognized present, persisting disease at the time of the accident, which aggravated the effects of the accident or which itself was aggravated by the accident, and which disease was a factor in causing the death. In this case however, Lewis was in good health not only doing his work daily without difficulty but taking part in sports and athletics. There were streptococci at the root of a tooth but they were apparently walled in and were not doing any perceptible harm. There are perhaps always germs of one kind or another in our bodies, confined quiescent and impotent, which may always remain so. The presence of these germs in an apparently normal and healthy body is not a "disease" within the meaning of the policy. The policy does not provide that the body must be free from every germ and defect, but it simply provides that it "does not cover death due to disease," such as those mentioned in the cases cited by the insurance company.

The circuit court of appeals agreed with the district court that Lewis died as a result of bodily injuries effected directly and independently of all other causes by accidental means within the meaning of the policy but reversed the judgment against the company, and ordered a new trial, because the record did not show, in the opinion of the court, that Lewis had suffered a continuous total disability from the date of the accident.—*Massachusetts Protective Ass'n v Lewis*, 72 F (2d) 952

Malpractice Sponge Left in Abdomen—The physician-defendant performed a cesarean operation on the plaintiff. The incision did not heal properly it ulcerated and discharged pus. About four months later another physician discovered a sponge in her abdomen. Thereafter the plaintiff sued the defendant and the case was tried by the court without a jury. The physician-defendant testified that the sponge found was of the type used for sponging "before entering an incision" and which should never be allowed to get loose in the body. He was unable to account for its presence in the patient's abdomen save that "its presence was the result of some accident about which witness can only advance a theory." The court rendered a judgment in favor of the physician and the patient appealed to the Supreme Court of Florida, division A.

It is negligence per se said the Supreme Court, for a physician to leave a sponge in a patient's body in the course of the performance of an operation. In such a case the burden of showing due care is on the physician. He cannot relieve himself from liability unless the sponge was so concealed that reasonable care on his part would not have disclosed it, and the patient's condition was such that, in his judgment, a special exploration for the sponge would have endangered the safety of the patient. Where a patient's condition is critical and the paramount requirement is to complete the operation in the shortest possible time, a failure to remove a sponge may or may not constitute actionable negligence, depending on the circumstances of the case the burden being on the physician to show to the satisfaction of the jury that the particular act was not blameworthy because of the supervening necessity to complete the operation without delay. In the present case the court continued, the defendant contended that a physician should not be deemed negligent when he has exercised every precaution under the exigencies of the case, to remove from the body of the patient all sponges, packs and other objects used in the operation, by removing all such objects discoverable by the sense of sight and touch and by keeping mental note of all such objects as were placed in the patient's body, and removing all of them to the best of his recollection at the time the incision is closed. But, answered the Supreme Court the evidence does not support this contention. The

defendant himself testified that he had to conclude the operation hurriedly for fear that the patient would die on the operating table before he could get the incision sewed up. But at the same time he admitted that the particular sponge, later found in the patient's body, was not an article that he had placed, or was required by any standard medical usage or practice to have placed, in the patient's abdominal cavity. On the contrary, he admitted in effect that the sponge was of a type used for sponging before entering an incision and had been allowed to get into the abdominal cavity as the "result of some accident about which witness can only advance a theory."

Even if it had been shown, said the court, that the defendant was required by the urgent necessities of the case to leave a sponge in the patient's abdomen, it was his legal duty so to inform his patient within a reasonable time thereafter so that she might seek as early relief as possible. The removal of all sponges used is part of a surgical operation and when a physician fails to remove a sponge he has used in the course of the operation he leaves his operation uncompleted and creates a new condition which imposes on him the legal duty of informing his patient and endeavoring with the means he has at hand to minimize and avoid untoward results likely to ensue therefrom.

The Supreme Court concluded that the trial court misapprehended the probative weight and legal effect of the evidence offered, reversed the judgment in favor of the physician, and ordered a new trial—*Smith v Zeagler (Fla)*, 157 So 328.

Trauma as Cause of Cancer—The plaintiff was injured, July 1, when an automobile driven by her husband collided with one of the defendant's wagons. Among other injuries sustained, one of her breasts was bruised and the overlying skin broken. Within seven weeks thereafter a mass developed at the site of the bruise, which was removed surgically, October 23. A pathologist found it to be "early carcinoma or cancer." The plaintiff sued the defendant, alleging that the cancer was caused by the accident. From a judgment for the plaintiff the defendant appealed to the Supreme Court of Wisconsin. While the appeal was pending the plaintiff died and the action was revived in the name of her administrator.

The defendant contended that the evidence was insufficient to show that the cancer was a result of the injuries sustained in the collision, that it is impossible in a particular case to say with a reasonable degree of certainty that cancer results from a specific injury. In the present case there was sufficient evidence, in the opinion of the court, to establish (a) the fact of injury or trauma, (b) that the injury was sufficiently severe to cause a bruising of the breast, (c) that prior to the injury there was no observable indication of the presence of a tumor, (d) that the tumor or cancer in question developed at the point where the injury was sustained, (e) that the presence of the tumor or cancer was observable within seven weeks from the time of the accident, and (f) that clinical diagnosis and roentgenologic evidence showed that the tumor was malignant. On the question of whether or not, in the face of these essential facts, it can be said with a reasonable degree of certainty that the cancer was caused by the injury sustained, the experts disagreed.

An expert witness, on behalf of the defendant, testified that the cancer did not result from the injury. The pathologist testified that his examination showed early carcinoma or cancer and that the breast also showed the results of chronic mastitis, some cysts and a hard area. He testified that the chronic condition had existed for several months, possibly longer, and that it might have been there for a year, that the cysts might have been there a number of weeks or several months or more. He expressed no opinion as to the cause of the cancer. An expert witness, on behalf of the plaintiff testified that the injury *might* have caused the cancer, but that physicians "are unable to look at or to examine in any known way any particular malignant growth and say that this did or it did not arise as a result of injury." Another witness stated that "Considering all the facts in hand, and the fact that so far as can be humanly told there was no tumor in her breast prior to the injury, and considering the fact that an acceptable period

had elapsed for such a cancer to develop to the size of a walnut, as given, and granting the fact that she had an adequate bruise, to the breast, it is my opinion that it is very probable that this cancer developed as a result of her injury." The testimony of this witness constituted the only evidence in the case, said the court, which tends to remove the question in dispute from the realm of doubt and speculation. The witness, however, assumed that there was an "adequate" bruise. Neither he nor any one else testified as to what an "adequate" bruise is or whether the bruise which the woman received was "adequate." He further assumed that there was no tumor in her breast prior to the injury, an assumption not warranted by the evidence. The evidence, said the Supreme Court, when analyzed, establishes no more than a possibility that the cancer resulted from the injury. Therefore the finding of the jury that the injury to the breast did cause the cancer was not sustained by the evidence.

During the trial a medical expert called by the defendant testified that he knew of no authority which stated that a sudden trauma may be followed by the development of a malignant growth. In cross-examining the witness, the plaintiff's counsel read an excerpt from a book on surgical pathology, with which the witness was familiar, to show that a reputable authority had made such a statement. Under the circumstances, said the court, the extract was admissible for the purpose for which it was offered.

In reversing the judgment of the circuit court, the Supreme Court remanded the case for a new trial, expressing the opinion that the facts in the case had not been fully developed.—*Brunns v Brandon Canning Co (Wis)*, 257 N W 35.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

*Treatment of Severe Preeclampsia and Eclampsia with Especial Reference to Use of Ephedrine W B McGee New Orleans—p 4
The Nervous Child W H McCaslan Union Springs—p 7
Gallbladder Visualization. W Wilkerson Montgomery—p 13

Treatment of Severe Preeclampsia—McGee gives the symptoms of severe preeclampsia as generalized edema, elevation of the diastolic blood pressure to more than 110 mm. marked increase in weight, oliguria or anuria, more than a heavy trace of albumin in the urine with red blood cells and casts, epigastric pain, headache and dizziness and eye symptoms or lassitude. He advises hospitalization if possible, careful measure of intake and output of fluids, a dose of 1 ounce of magnesium sulphate, and restriction of fluids to 1,000 cc. a day if edema is present. Bidaily blood pressure and urine examinations should be made and the patient should be put on an eclamptic diet to be used not more than five days. Fruit and fruit juices, water and fruit ices, berries and melons, baked Irish potatoes, asparagus, carrots and lettuce. If the blood pressure is below 140 systolic and 90 diastolic with oliguria, three-eighths grain (0.024 Gm.) of ephedrine sulphate may be given orally every four hours. In eclampsia, in the event that convulsions or coma ensue, the treatment is wholly empirical. The fall in blood pressure, and corresponding decrease in urinary output caused by barbitol preparations, is counteracted by the administration of three-fourths grain (0.048 Gm.) of ephedrine sulphate, hypodermically, every four hours. The hypertension seen in eclampsia is undoubtedly a compensatory factor of the body in its attempt to excrete urine, chlorides and toxins through the already damaged kidneys. The ephedrine usually causes an elevation of blood pressure (Chen) this is followed by a relaxation of the spasms in the capillaries and an increased blood supply to the kidneys and brain. Any drug that tends to lower the blood pressure is contraindicated. If the convulsions persist after the intravenous injection of sodium amytal, one-fourth grain (0.016 Gm.) of morphine is indicated, followed by 3 grains (0.2 Gm.) of sodium amytal intramuscularly or 10 cc. of 25 per cent solution of magnesium sulphate, intramuscularly, repeated every three to six hours if necessary. If there is an initial low blood pressure, three-eighths grain of ephedrine should be given every four hours. Spinal puncture may help to relieve the intracranial pressure if there is an increase in spinal fluid unfortunately, the edema is usually incorporated in the brain tissues.

Culture Mediums for Routine Diphtheria Cultures—According to Laybourn, changes in reaction occur during the storage of blood serum preserved with chloroform, which influences the reaction of coagulated serum mediums in which such serum is used. The color and consistency of serum-bouillon mediums are indicative of the reaction. The addition of sodium hydroxide solution to serum bouillon mixtures causes a hydrolysis which, if extensive, makes the consistency of the coagulum unsatisfactory for use. Human and hog serums require the use of less

alkali in the adjustment of the reaction than beef, sheep and horse serums, and they are preferable for this reason. Beef, sheep and horse serums form a softer coagulum than human and hog serums, which also makes them less satisfactory for use in throat culture mediums. The reaction of bouillon-serum mixtures changes during coagulation and sterilization, and allowance must be made for drift of reaction in adjusting the uncoagulated mixture. *Staphylococcus aureus* produces sufficient acid from the dextrose in Loeffler's medium in eighteen hours to influence greatly the luxuriance of growth, morphology and staining of *Corynebacterium diphtheriae*. A formula for diphtheria culture medium is suggested, which supports luxuriant growth of *Corynebacterium diphtheriae* with typical forms of the organism in the presence of *Staphylococcus aureus*.

Extraperitoneal Approach to Lumbar Sympathetic Nerves.—In performing a lumbar sympathectomy, Flothow makes an incision almost transversely at the level of the umbilicus, extending from the edge of the rectus muscle to the flank. The skin and subcutaneous tissues down to the fascia of the oblique muscle are dissected widely to expose a large portion of the external oblique fibers. An incision is made in the fascia of the external oblique muscle parallel with its fibers, well laterally, almost to the costal margin down to the fascia of the rectus muscle. The fibers of the muscle are separated and retracted widely, exposing the internal oblique muscle. The internal oblique is separated in the direction of its fibers

from above the crest of the ilium again to the rectus muscle and retracted widely. The transversalis muscle is separated in the direction of its fibers as far as the exposure will permit. The transversalis fascia is opened and an extraperitoneal dissection of the retroperitoneal tissues is made. The retroperitoneal tissue, the peritoneum and its contents are pushed medially until the psoas muscle is reached. The abdominal contents are retracted medially, the fascia covering the psoas muscle is opened throughout the length of the exposure, and the aorta or the vena cava is retracted medially. The sympathetic ganglions will be found lying under either the aorta or the vena cava on the bodies of the lumbar vertebrae at the medial edge of the insertion of the psoas muscle to the vertebrae. The entire chain from the first to the fourth lumbar ganglions inclusive is exposed. After the operation is finished, it is only necessary to take a few sutures in the transversalis muscle, a running suture in the internal oblique muscle and a running suture in the fascia of the external oblique. The operation was done in as little time as twenty-five minutes. The operation is without shock to the patient. It offers a rapid entrance and an adequate exposure.

Abscess of the Thyroid.—Henderson states that thyroid abscess occurred only four times in 545 consecutive thyroid cases. The most common symptoms are deep unilateral pain in the thyroid region, painful swallowing, hoarseness and malaise. There is sometimes tumefaction of the gland, with tenderness and reddening of the overlying skin. The chin is often depressed on the sternum during swallowing. The temperature curve is septic in type with a tachycardia disproportionate to the pyrexia. A differential diagnosis must be made from acute infections of the upper respiratory tract, cervical lymphadenitis, hemorrhage into an adenoma, malignant conditions, Riedel's struma and, very rarely, thyroglossal or branchial cysts and cystic hygromas. The complications are those attendant on spread of the infectious process into the surrounding tissues. The treatment comprises prevention of suppuration if possible. When it does occur, early, adequate and prolonged drainage is indicated. Prognosis is guarded. It is poorer in the suppurative than in the nonsuppurative variety. Four cases are reported in patients aged from 2 to 46, three of whom were males. The etiologic agents were *Bacillus influenzae*, a non-hemolytic streptococcus and a hemolytic streptococcus. In the fourth case cultures did not yield any organism and it is possible that this was due to the tubercle bacillus or less likely to one of the higher micro-organisms. There was recurrence, probably due to insufficient drainage, in two cases. The author concludes that tuberculosis and other granulomas of the thyroid may occur but are rare.

Bacteriophage in Treatment of Urinary Infections.—According to Wehrbein, only relatively superficial infections can be treated by bacteriophage application. Pyelitis and cystitis are ideal conditions for this type of therapy, but, if kidney abscesses have occurred or if the prostate or seminal vesicles are infected, cure cannot be expected by means of bacteriophage therapy. The bacteriophage must be quickly effective before it is used. It should lyse one billion micro-organisms per cubic centimeter in from three to five hours. Prolonged incubation should show no second growth. The bacteriophage should be placed in as large a quantity and in as concentrated a form as possible in the infected area. If the kidney pelvis is infected, the pelvis should be actually filled with the bacteriophage solution by the use of a large catheter. If only the bladder is infected, at least 50 cc should be put into the empty bladder. All antiseptics must be avoided. If the first application of the bacteriophage is unsuccessful, it is useless to repeat. Of thirty-four cases treated by the author, ten were acute pyelitis cases. Of these, seven were cured through one application. The other three were improved but not cured. Of the twenty-four chronic and subacute cases of pyelitis, only five were cured, thirteen were benefited and six were failures. In addition to the thirty-four cases treated, the author successfully used bacteriophage in postoperative infections and in incised abscesses.

The Larval Treatment of Osteomyelitis.—Ferguson and McLaughlin widely incise the soft tissues and saucerize the bone to expose the involved area. The wound is packed with

gauze, which is not changed for at least three days except to renew the outside dressings. The muscle and skin wound is lined with petrolatum gauze to facilitate removal of the packing and to minimize the associated pain. On the fourth day the packing is removed. When the capillary ooze has ceased, the wound is irrigated with warm physiologic solution of sodium chloride and the maggots are introduced. Several methods of introducing maggots were used, all of which proved satisfactory. In small wounds it is frequently possible to transfer the maggots from the bottle to the wound with the handle of a sterile scalpel. When the larvae are embedded in food material, a small amount of physiologic solution of sodium chloride is poured into the bottle. The maggots usually float to the top of the fluid after gentle shaking. They may be caught on several layers of sterile gauze as the solution is poured from the bottle. The maggots are shaken from the gauze on the wound. In cases in which the compress form of dressing is used, the gauze containing the maggots is introduced directly into the wound. The chief complication observed is the marked skin excoriation produced by the wound secretion after introduction of the maggots. Pain and discomfort are complications frequently noted. These symptoms are due to the introduction of too many maggots into the wound. Removal of some of the maggots usually relieves most of the discomfort. Maggot therapy is especially effective in removing necrotic areolar tissue. Maggot action alone gives a more complete result than can be obtained by excision and without injury to recovering tissue. Maggot action is less rapid but distinctly helpful in attacking the necrotic fibrous tissue. Maggot therapy is useful not only in the treatment of osteomyelitis but in any other wound containing sloughing tissue that can be exposed by adequate incision. The authors report the successful treatment of thirteen cases of osteomyelitis, eight carbuncles, six sloughing ulcers of the leg, seven cases of gangrene and thirteen other lesions of soft tissues.

Biologic Effects of Thymus Extract—Rowntree and his associates found that the thymus extract prepared from the thymus glands of young calves by Hanson when injected intraperitoneally, seemed to increase the weight and growth of prepubertal male and of mated mature female rats but exerted no noticeable effect on the new-born animals. Treatment of parent rats seems to increase slightly the number and size of the litters and the weight of the young at birth. The most striking biologic effects are observed in the offspring of successive generations of rats continuously treated by intraperitoneal injection and consist of accruing acceleration in growth and development, early eruption of teeth, appearance of fur, opening of the eyes, descent of the testes and opening of the vagina. While precocity was lacking in the early litters born of thymus treated parents in the first generation it appeared in later litters. This precocity is apparently not effected through the mother's milk. Young rats from thymus treated strains occasionally matured and bred early whether they received injections of

thymus extract or not, as both thymus-treated and control rats in the F_1 generation cast litters at forty-two and forty-five days, respectively. It appears that thymus extract (Hanson) affects the fertility and rate of growth and development of white rats. The interruption of thymus administration for one generation nullified to a large extent the effects of the previous administration of thymus, even though the treatment may have extended through several generations of rats. Rats receiving thymus extract appear unusually docile, healthy and contented. Excessive amounts of thymus extract result in toxicity, as evidenced by increasing auriculoventricular dissociation and eventual heart block.

Circulatory Changes in Angina Pectoris—Shambaugh employed essentially the procedure described by Sutton and Lueth in his investigations on the effect of experimental angina pectoris on the blood pressure, the effect of the elevation in the blood pressure on the production of experimental angina pectoris, and the effect of increasing the heart rate on the production of experimental angina pectoris. His observations on the effect of mechanical interference with the coronary blood flow in unanesthetized dogs are in accord with those of previous observers. There is a constant typical reaction that, without doubt, signifies pain. A graphic record of this reaction can be made only by noting changes in the respiratory tracing. The changes in the respiratory tracings are merely confirmatory and, in addition, serve to record the time relations of the response. When the respiration is altered with the pain reaction, and this is the rule, the author found that an acceleration is a more accurate indication than is an increase in amplitude. It was found unnecessary to carry the stimulus beyond the point at which a moderate degree of discomfort was produced. The experimental observations lend support to the clinical concept that the elevation of blood pressure frequently observed in angina pectoris is more likely the cause than the result of the attack. The tachycardia may also play a similar part, although this has not been demonstrated in the present experiments. The fact that these circulatory changes may precipitate attacks in certain cases of angina pectoris does not mean that they are the important factors in all cases of the disorder.

Action of Oil of Peppermint on Stomach—Meyer and his co-workers discuss the action of oil of peppermint on the motility and secretion of the stomach of patients having peptic ulcer. They have made the observation on themselves that the chewing of peppermint candy or lozenges relieves pain caused by hunger and by distress after a heavy meal. Oil of peppermint when given by itself or with a secretory stimulant depresses the secretion of acid by the stomach. The chloride content has been determined on samples of gastric juice before and after the introduction of alcohol and of alcohol and oil of peppermint into the stomach. The level of the chlorides was not affected when the free and combined acidity decreased after alcohol and oil of peppermint were given. This may be indicative of a change in the mechanism of secretion, i. e., suppression of the free hydrochloric acid and possible increase of the sodium chloride. Menthol was found to have no acid depressing effects. Experiments on dogs with gastric pouches indicate that the action of the oil is probably a local one on the mucosa of the pouch. The authors are treating a number of peptic ulcer patients with the essence of oil of peppermint. Relief of pain has definitely been noted in a few, but the period of observation is not sufficient to warrant a statement. In view of the popular use of peppermint for relief of gastric distress and the interest and importance of the mechanism of pain in ulcer, it might readily be argued by those who favor the theory of acid in relation to pain that the relief of symptoms following the use of oil of peppermint is due to a diminution in free acid. However there is still considerable dispute as to the factors involved in pain in peptic ulcer. In a previous article one of the authors proved that relief of pain occurred independent of the degree of free acidity in patients with chronic peptic ulcer. It was suggested that the relief of symptoms in patients with peptic ulcer following the use of foreign protein was due to an improvement of the circulation in the vascular bed in and about the ulcerated area, and the hypothesis was advanced that the pain of ulcer is due to ischemia and asphyxia resulting from depletion of the vascular bed in and about the ulcerated area. It was on the basis of this conception of the mechanism of

pain in peptic ulcer that the effects of an essential oil were tried, a substance that might cause a local hyperemia. The sense of warmth and the feeling of ease following the ingestion of essence of oil of peppermint are well known.

Continuous Gastric Siphonage—According to Kasler and Miller, continuous siphonage may be used with success in post-abdominal operations in which acute dilatation of the stomach, gastric retention and upper intestinal ileus are likely to occur or have occurred. The comfort of the patient is greatly helped by relief from vomiting and ability to drink water freely. The apparatus is simple and efficient but requires care in handling. It consists of three units: a receptacle, a suction chamber, which is composed of the barrel of a 20 cc. syringe fitted with a two-holed rubber stopper, and a basin. The rubber stopper is fitted with two glass connectors. One is straight and is connected by rubber tubing to the receptacle above. The other connector is curved and joins the nasal tube. The suction chamber empties into the basin by means of a suitable length of rubber tubing, the end of which is beneath the water in the basin. The receptacle is filled with water and allowed to drip at the rate of from 60 to 80 drops (4 to 53 cc.) per minute. The water runs out of the suction chamber through the tube from the chamber to the basin and creates a vacuum behind it, the force of which is exerted through the nasal tube. Soon after the suction is started, the stomach contents will appear and pass through to the basin. Continuous siphonage cannot be maintained by the simple use of a nasal catheter because the entrance of air and gas into the system interrupts the siphonage. By means of the apparatus the functional capacity of the stomach can be determined and the amount of fluid passing through the pylorus in either direction can be measured in cubic centimeters. The patient is encouraged to drink as much fluid as he likes and, as the gastro-intestinal tonus improves, increasing proportions of the oral intake will go through the pylorus instead of being removed by suction. Subtracting the oral intake from the difference between the amount in the basin and the amount placed in the receptacle above gives a certain quantity of fluid in cubic centimeters. This figure, known as the pyloric balance, tells what has happened to the fluid taken by mouth. When the amount recovered from the stomach is greater than the oral intake, the pyloric balance is negative, and when the amount taken by mouth is greater than the amount recovered from the stomach, the pyloric balance is positive. When continuous

siphonage is interrupted by a plug of mucus in the nasal tube, the tube should be withdrawn about one inch and reinserted. If this is unsuccessful in reestablishing the suction, the nasal tube should be disconnected and some water injected to clear it. The nasal tube should be removed, cleansed, sterilized and inserted into the other nostril every twenty-four hours. The authors report four cases in which continuous siphonage was employed. In the first case the patient was relieved of ileus and hiccups by this method when other methods had failed. In the second and third cases, early manifestations of ileus were present and these were checked. In the fourth case, postoperative vomiting and retention were efficiently relieved, and the apparatus added materially to the patient's comfort.

Manifestations of Chronic Encephalitis—Barer discusses the more common types of chronic encephalitis that result after an epidemic of epidemic (lethargic) encephalitis. The parkinsonian syndrome is most common and presents itself in various degrees at various intervals after the acute infection. The patient first complains of slowness of movement, stiffness, pain in the back of his neck, loss of vitality, shakiness and weakness. Some flexion of the entire spine is usually present. In walking there is a loss of the normal coordinated movement of swinging the arms and some festination. The eyes are fixed straight forward and there is some impairment or loss of the capacity for ocular convergence. The face has a blank, fixed expression. The skin is often greasy and the mouth is held partly open. The voice is weak, with articulation and phonation impaired. The muscular rigidity that is present in the paralysis agitans syndrome of chronic encephalitis is known as the cog-wheel type of rigidity. With this rigidity the paralysis agitans tremor sometimes develops. It is not seen as often in chronic encephalitis as it is in senile or true paralysis agitans. In all cases the tremor is synchronous and is increased in amplitude by emotion or exertion. Other symptoms and signs are palidness, micrographia, paradoxical kinesia, akathisia and disturbed liver function. The condition is progressive and after a variable length of time the patient becomes completely incapacitated. Oculogyric spasms of chronic encephalitis are pathognomonic of chronic encephalitis. With this condition the patient complains that his eyes suddenly roll upward and want to stay there. There is absence of pain, loss of vision and flashes of light or scotomas. There is sometimes an associated closing of the eyelids, turning of the head upward and to one side, and the desire to sleep. The eyes return to normal as suddenly as they go into the spasm. In the ophthalmoplegic type of chronic encephalitis there is sometimes inequality of the pupils with some impairment of the pupillary reflexes to light and in accommodation. There may be a ptosis of one or both eyelids, dimness or mistiness of vision or perhaps even definite muscle palsy. This type is frequently seen in conjunction with the paralysis agitans syndrome and the oculogyric spasm types of chronic encephalitis. In the narcoleptic type of chronic encephalitis there is an irresistible desire to sleep, which comes on at any time in the day, and the patient must go to sleep for a variable length of time. On awakening he is much refreshed. The second symptom, which sometimes occurs with the first, but never alone, is cataplexy. The author mentions the hemiplegic type, the myoclonic type, respiratory tics, tics of the facial and deglutatory muscles, the diabetes insipidus syndrome, the neuritic types, inversion of the sleep mechanism, convulsions, amyotrophic lateral sclerosis and myasthenia gravis. Chronic encephalitis is not the sequel of acute encephalitis, because the

clinical picture described does not appear immediately following the acute infection, the condition is progressive, and the histologic picture indicates an active change in the parenchyma, which is glial infiltration and perivascular infiltration. The parkinsonian syndrome of chronic encephalitis results from lesions in the substantia nigra. The symptoms being due chiefly to the death of nerve cells, attempts at specific therapy are hopeless, but palliative measures may be used.

Patch Test for Gold Hypersensitivity—Lichtenstein observed that exfoliative dermatitis, rashes, gastro-intestinal symptoms and neuritis in patients treated with gold compounds are due to the development of hypersensitivity. The patch test with 33 per cent gold sodium thiosulphate in hydrous wool fat is positive in about 50 per cent of those treated including all those presenting the complications mentioned and persists over a long period of time. The patch test, if performed frequently, will usually be found positive before complications occur. Patients treated with gold succinimide become sensitive to the patch test but rarely show any complications. Kidney injury cannot be correlated with hypersensitivity but appears to be a direct toxic effect of the gold compounds.

Treatment of Acute Purulent Arthritis—Jones reports eight cases and describes the method of treatment. After aspiration of the joint has given evidence of a purulent effusion and general and local symptoms have indicated more than a mild effusion, an incision is made into the joint. In the case of a knee, the incision is about 1 inch long, vertical and to one side of the proximal part of the patella. The joint is washed out carefully with physiologic solution of sodium chloride at 110 F, delivered through a catheter under moderate gravity pressure for a period of from twenty to thirty minutes. The joint is permitted to fill with fluid like a balloon and then to collapse when the fluid is allowed to escape, carrying away pus fibrin and other debris. An attempt is made to gain a water-tight closure of synovial membrane and capsule. Usually the skin also is closed. A cast is applied to afford rest to the joint and the progress is measured by noting the patient's general condition, the temperature, pulse, respiration, blood picture, urine and local symptoms and signs in the knee. The patients responded well to treatment. Trauma and a distant focus were closely related etiologic factors, causing the purulent arthritis in six of the eight patients. One cannot lightly dismiss

this relationship in a majority of the cases. In one case, in which osteomyelitis of the tibia developed associated with a septic knee joint, the septic tooth and the trauma to the region of the knee were both factors in the development of the osteomyelitis. One patient associated the onset of trouble with a very definite wrench to the knee while playing tennis, and he presented definite foci of infection. The surprising resistance of the synovial membrane to infection is illustrated by one case in which marked distention of the knee joint was discovered ten days after drainage of the adjacent tibia for osteomyelitis. The resistance of the synovial membrane to infection is probably associated with the bactericidal properties of the synovial fluid.

Treatment of Chronic Polyarthrititis by Parathyroidectomy—Schkurov investigated forty cases of chronic rheumatic polyarthrititis and spondylarthrititis treated by parathyroidectomy. Many of the patients were in the late stages of these diseases and had permanent deformities. Had parathyroidectomy been performed at an early stage, more satisfactory results would have been obtained. Parathyroidectomy cannot have any effect on the already ankylosed joints nor can it, without any subsequent orthopedic treatment, correct permanent deformities. Parathyroidectomy prevents the development of ankylosis, does away with rigidity of joints and creates the most favorable conditions for subsequent methods of correction of deformities and restoration of joint movement. The immediate results of this operation are good in almost all cases. Of the forty cases investigated, the late results proved to be good in twenty-two. This operation is only one means of prophylaxis and treatment of chronic rheumatic polyarthrititis and spondylarthrititis. In addition, it is essential to determine in each case the cause of illness and to outline a plan of treatment accordingly.

Volkman's Contracture—Jones found that certain elbow injuries, notably supracondylar fractures, are seen, together with a painful swollen elbow, an absent radial pulse and a cold anesthetic hand. If, after careful reduction, there is still diminished or absent radial pulse with loss of sensation of the hand, loss of voluntary motor power and pain in the elbow increasing hour by hour, Volkman's contracture is impending. Immediate operation is necessary. The operation of choice is fasciotomy. The author states that Volkman's contracture may occur in the absence of splints or tight bandages and that it is caused in certain cases by interruption of arterial circulation. This interruption may be due to direct injury to the artery itself or to intrinsic pressure on the artery caused by hemorrhage within the fascial envelop. The collateral circulation is sufficient if given an opportunity to function. The operation of fasciotomy, performed early, gives this opportunity.

Spike Fixation of Fractures of Neck of Femur—Gaenslen used the following method for the reduction and subcutaneous spike fixation of fractures of the neck of the femur under scopolamine-morphine anesthesia in ten cases. Roentgenograms of the two hips in the anteroposterior view are taken with the sound hip rotated inward about 15 degrees to prevent a foreshortened appearance of the neck, due to anterior inclination. This view discloses the site and character of the fracture on the injured side and the normal angle of the neck and the shaft as well as the length of the neck on the well side. A lateral view of the sound hip is taken to determine the angle of anterior inclination. Previously prepared posterior plaster half shells are applied to the lower extremities, with the hips and knees flexed to right angles to provide muscular relaxation. Strong upward traction is made in the direction of the long axis of the femur. Lateral pressure on the trochanter is made to correct possible anteroposterior displacement. Reduction was completed by these maneuvers. Abduction is added to fix firmly or to lock the fragments and also to make possible the taking of roentgenograms in both anteroposterior and lateral views without shifting the patient's position. To facilitate introduction of the spikes, the hip is abducted to bring the neck parallel to the surface of the table and rotated inward sufficiently to allow for the anterior inclination of the neck, thus bringing the neck not only parallel to the table but perpendicular to the long axis of the patient. The skin is surgically prepared and a sterile, coarse netting is stretched over the affected hip and held taut by rubber bands to displace the

heavy adipose layer. The trochanter limits are indicated on the skin surface by thrusting three hat pins into the hip region, parallel to the long axis of the neck, so that they pass tangentially over the anterior and posterior margins and the tip of the trochanter. With these pins to serve as landmarks, the cross section of the neck can be more readily visualized. This section is roughly 1.8 by 2.5 cm in diameter. Into the center of this area two Kirschner wires are introduced about 1 cm apart and to a depth of about 12 cm. The wires are identified with lead markers, and anteroposterior and lateral roentgenograms are taken. If the Kirschner wires are not satisfactory, efforts at more perfect reduction and insertion of guide wires are necessary. If the fracture surfaces overlap even slightly, the target is naturally reduced in size and the difficulties of spiking are materially increased. The first fixation spike is introduced through a tenotomy puncture wound and is drilled into the bone to a depth of from 3 to 4 cm. The spike is driven deeper with a mallet until its tip just engages the cortex of the head. If the placement of this spike is satisfactory, from two to four additional spikes are inserted. The hatpins and the two Kirschner wires are removed. The heavier fixation spikes are identified with lead markers and further roentgenograms are taken. These disclose whether the fragments are properly transfixed and whether the spikes are driven to the desired depth. If the position is satisfactory, the spikes are cut as short as possible. The skin is drawn over the ends and a dressing is applied over the puncture wounds. The patient is placed in bed with the leg resting on a pillow under the knee. Sling suspension may be added for comfort and to initiate active motion even on the first day. The spikes are removed in about three months. The author obtained good results in all cases.

Correction of Rachitic Deformities by Preliminary Decalcification—Finkelstein treated fifty cases of rachitic deformities of the lower extremities by the following method. Roentgenograms and photographs are taken. In bilateral deformities of the lower extremities, a double plaster spica is applied from waist to toes. The patient is kept in bed. All antirachitic measures are suspended. After four weeks, another roentgenogram is taken and compared with the original to ascertain the degree of atrophy. The patient is then prepared for anesthesia. After the casts have been removed, the limbs are slowly bent into a slightly overcorrected position. Excessive force is contraindicated, and complete transverse fractures with displacement of fragments should be avoided. In multiple deformities, the tibiae, the fibulae and the femurs can be corrected at one sitting. Extreme overcorrection of the deformities is unnecessary. Immediately after the correction, a double plaster spica is applied and, when the plaster is thoroughly dried, roentgenograms are again taken to determine the extent of improvement. Several days after the correction, general antirachitic measures are instituted, such as a high vitamin diet, cod liver or halibut liver oil with viosterol calcium phosphate and exposure to ultraviolet rays. Massage and exercises are begun as soon as the roentgenograms show sufficient recalcification, and gradually increased weight bearing is encouraged. The results of treatment have been satisfactory. No major complications were encountered. The hospitalization period rarely exceeded ten days.

Oral Immunization to Colds—Rockwell and his collaborators immunized a large group of persons orally to the secondary invaders of colds, using a vaccine made up of heterophile antibodies. The 500 patients who took the vaccine came from various walks of life and the 536 persons used as controls were chosen from the same environment. The average number of colds each patient had annually in the past three years age, sex, occupation and allergic history was obtained before the vaccine was given. The oral cold vaccine was made from pneumococci and streptococci. Since the desired immunity was a nontype specific heterophile active immunity, a single pneumococcus strain was used. This strain was DR-I, a well known nonpassaged, and mainly rough, variant from the Neufeld type I pneumococcus. The streptococcus was a hemolytic mouse-virulent laboratory strain. The treatment consisted of the ingestion of one capsule of starch adsorbed vaccine containing 100 billion pneumococci and 100 billion streptococci with a half glassful of cold water each morning before breakfast for seven consecutive mornings, after which term one capsule each week was taken throughout the season. Of the 500 treated cases thirty-eight had a history of continuous colds, while 425 had a history of from one to eight colds annually per person. Among the 536 controls, nine had a history of continuous colds, while 527 had a history of from only one to eight colds annually per person. Among the forty-seven patients who gave a history of continuous colds, the thirty eight who were given the oral cold vaccine had, for that year, a total of only forty-one colds, thus passing from a stage of continual coryza to an average of 1.08 colds per person, while of the nine persons used as controls only one reported a less severe type this year. Among those who for the past three years had a history of from one to eight colds annually per person, 462 patients having a yearly average total during the previous three years of 1,400 colds or 3.03 colds per person annually, while taking the vaccine this year had a total of only 604 colds, or an average of 1.3 colds per person and 1.73 colds less per person, a decrease of 57 per cent. The 527 persons used as controls had a yearly average total for the past three years, of 1,314 colds, or 2.49 colds per person annually. During the school year 1933-1934 this group had a total of 1,156 colds, or 2.19 colds per person, which is 0.3 cold less per person, or a decrease of 12 per cent. The essential decrease due to the oral cold vaccine is thus 45 per cent. The relationship between the response of the individual to the heterophile antigen and his incidence of colds is given in a separate article.

Lumbar Localization of Paralysis in Experimental Poliomyelitis—Faber experimented with intranasal inoculations of virus in fifty-seven monkeys to determine the region of initial paralysis. He believes that the infection beyond any reasonable doubt entered through the olfactory nerves and passed through the brain stem and spinal cord from above downward. Paralysis occurred first in the arms of twenty-five monkeys, in the legs of twenty-seven and in the arms and legs of five. These experiments, in which entrance of infection from the gastrointestinal tract can be ruled out and in which the legs were more often first involved than the arms, demonstrate that initial involvement of the lumbar cord cannot properly be used as evidence for the theory of the gastro intestinal portal of entry. They prove that the virus in descending through the cord can produce its first manifestations in the lower segments. Having observed that the virus is present in all levels of the cord including the cervical, before and when paralysis appears, the author explains the earlier and greater lumbar area paralysis by the fact that the anterior horn cell in that area are somewhat more susceptible than others to attack by the virus of poliomyelitis.

Effect of Anterior Pituitary Extract on Blood Sugar—Venkatachalam and Ratnagiriswaran studied the general effects produced in the cat by the administration of anterior pituitary extract containing the growth promoting hormone. They found that the injection of 1 cc. of the extract, corresponding to 0.5 Gm. of the desiccated gland, reduced the blood pressure almost to zero and produced respiratory failure. If the quantity was given slowly and gradually, there was an initial fall of blood pressure followed by a marked and persistent rise and the animals could survive doses up to 15 cc. If this amount was exceeded, the animals died of convulsions and respiratory failure. The extract increased the blood sugar to nearly twice the normal value and this rise was enhanced by vagisection or

atropinization. Vagisection or atropinization also produced a rise of blood sugar. Gonadal extracts reduce the blood sugar and counteract the rise due to the administration of anterior pituitary extract, this effect was not observed after vagisection or atropinization. The vagal center was made more sensitive to electrical stimulation by the administration of gonadal extract, whereas anterior pituitary extract had the opposite effect and it was less sensitive to electrical stimulus. The hyperglycemic effect of anterior pituitary extract has been shown to be the result of its depressant action on the vagal center. The authors are observing the mode of action of the anterior pituitary lobe on the vagal center and the results obtained so far indicate that the depressant action of the lobe may be due to the stimulation of the thyroid.

Antirabic Immunization.—Shortt and his collaborators describe the method of preparation, standardization, concentration of antirabic serum and the use of antirabic serum as an adjunct to treatment with phenolized dead virus, which they consider to mark an advance on the present methods of treatment by vaccine alone. Treatment by one dose of a combination of fresh living fixed virus and antirabic serum has been shown to have a considerable immunizing value although the main effect appears to have been exerted by the live virus, the serum being used mainly to render the use of the live virus more safe. They demonstrate that the use of fresh living fixed virus as an adjunct to treatment with phenolized dead virus is the most effective method yet tried for the immunization of dogs and, therefore, probably of other animals also. They believe that the future lines of advance toward the most efficacious means of producing a solid immunity against rabies will be along the path of utilization of antirabic serum and fresh live fixed virus, possibly combined with the use of a dead vaccine.

Mental Disorders and Diabetes Mellitus.—In studying the relationship between mental disorders and diabetes, Menninger observed thirty cases of mental disorder associated with diabetes, ninety-three cases of uncomplicated diabetes and 400 uncomplicated cases of mental disorder. The study covers the psychologic picture in diabetes, the types and courses of mental disorder associated with diabetes and the mental symptoms with hypoglycemia. He found that certain fluctuations of a specific type occur with sufficient frequency in diabetic persons to suggest a descriptive picture of the "diabetic personality." Diabetes does not determine the type of frank mental disturbance that may be associated with it, except in a small proportion of cases referred to as toxic psychoses or true "diabetic psychoses." That psychologic conflicts may be an important etiologic factor in many cases of diabetes seems probable. Gross psychologic trauma may initiate diabetes, but the more important unconscious conflicts might conceivably be the cause of the entire picture, even in these cases, and possibly operate in

some instances to produce diabetes in the absence of any external event or situation. Mental disorder and diabetes never occur independently in the same individual. They may occur independently at different times, but once associated they bear a relationship to each other.

Gold Treatment of Rheumatoid Arthritis—According to Hartfall and Garland, chrysotherapy in relation to rheumatoid arthritis is still in the experimental stages. They treated 100 cases in two years with excellent results in 70 per cent and some improvement in 90 per cent of the cases. These included many cases of long duration with gross disability. Owing to the marked variation in susceptibility, no rules as to dosage can be laid down and treatment must be individualized. In some cases, treatment must be prolonged for two years or more. Probably the doses employed are still too large and it is possible that the interval between courses should be not less than three months. Toxic reactions occurred in fifty cases. These are usually mild and do not contraindicate further treatment. Hemorrhagic reactions and exfoliative dermatitis, however, may be fatal and no more gold should be given to patients who develop them. Other than gross renal or hepatic disease, the authors found no absolute contraindication to gold therapy before the onset of these serious reactions. Gold therapy should be undertaken only by those who are fully alive to its dangers. The patient should be warned of these possibilities. The urine should be tested before each injection. Special care must be taken after the occurrence of toxic reactions. It is essential that every patient should be seen every week during and for three months after each course of treatment.

Proctitis in Gonorrhea of Women—Clements and Hughes investigated 160 patients suffering from gonorrhea of the genito-urinary passages or under tests of cure or under suspicion. Gonococci were found in the rectal secretion of sixty nine. In the majority of cases, obvious signs and symptoms were absent. By cultural methods an important proportion of cases are discovered that would be overlooked if tested only by smear on microscopic slide. In eight cases under test of cure, gonococci

were not found in the secretions of urethra and cervix either at the time of the rectal examination or later. In seven other cases examined under suspicion, no gonococci were ever found in secretions from the genito-urinary passages. Gonorrheal proctitis does not appear to be self limited. Treatment by irrigation with potassium permanganate (from 1 4,000 to 1 8,000) proved disappointing, but acriflavine hydrochloride 1 5,000 seemed satisfactory. Microscopic and cultural examination of the rectal secretion is clearly required for every woman in whom there is any question of a gonococcal infection.

Incidence of Rheumatic Infections in Australia Note E L. Cooper—p 714
Congenital Ectodermal Dysplasia L Dods—p 715
Malrotation of Midgut Loop with Superimposed Volvulus Case P L Hipsley—p 716

Diagnosis and Treatment of Lung Abscess—Fitts states that acute lung abscess closely resembles bronchopneumonia. Cough in the early stages is not very characteristic, frequently the patient complains of a bad taste, and offensive breath is noticed after coughing. Dyspnea may be severe. Hemoptysis occurs in most cases, and rigors, sweats and high temperature may occur at one end of the scale, at the other, the constitutional symptoms and such signs as the temperature may be slight and intermittent. Physical signs of lung abscess are clubbing of the fingers, which sometimes occurs in association with subphrenic abscess, in which there is no communication with the thoracic cavity, widening of the palpebral fissures and a slight degree of exophthalmos. The sputum should be examined for tubercle bacilli, anaerobic organisms, spirochetes, hydatid hooklets, amebas or sulphur granules of *Actinomyces*. There is no single feature, even to the duplicity of the roentgenograms that may not be common to lung abscess and carcinoma of the lung. By blockage of a bronchus, bronchiectasis may be set up distal to the growth, and this may develop into a bronchiectatic abscess. Abscess formation may occur in the growth itself, or in some slow growing tumors in the parenchyma of the lung central necrosis and cavity formation may take place. Sometimes empyema is diagnosed on physical signs and exploratory puncture, the pus being aspirated from a lung abscess. A roentgenogram would prevent this mistake. Septic bronchopneumonia may terminate cases of lung abscess in the acute stage. Empyema may complicate it and death may occur from toxemia. Cerebral abscess may occur even in the chronic abscesses in a late stage and seems to be more frequent after operative intervention. The author advocates complete discharge of the abscess contents through the related bronchus and closure of the cavity. A chronic cavity in the lung is a potential source of danger from recurring infection, hemoptysis and secondary bronchiectasis in the neighboring portions of the lung and from cerebral abscess. Medical treatment of lung abscess should be continued until the patient is definitely going down hill, until the successful evacuation and closure of the cavity occur or until such time as it is obvious that the cavity is not going to close. If the patient is definitely going down hill surgical intervention may be life saving. Pleural adhesions are first promoted with an extrapleural iodine pack. A week later an exploratory puncture is made and, when pus is found, a track is produced by diathermy along the needle, which has been left in place. Bronchial fistulas are always present, and often, after closure of the cavity, a fresh pocket forms. Chronic cavities are difficult to close. Some of them are said to be lined with stratified epithelium. When there are widespread bronchiectases and not a very large cavity thoracoplasty may be necessary. For chronic abscess suitably situated, whether or not there is secondary bronchiectasis, lobectomy should be seriously considered. Artificial pneumothorax should be looked on as a means of closing a cavity that is not too thick in the wall or as a means of controlling hemoptysis. In some cases there is grave danger of rupture into the pleural cavity and of the development of pyopneumothorax. The author believes that every chance should be given the patient to close the cavity by postural and bronchoscopic drainage whenever possible and that operation should be performed only when these fail.

Longevity of Larvae of *Wuchereria Bancrofti* Cobbold in *Culex pipiens*—Hu found viable infective larvae in the labia of two mosquitoes sixty-eight days after the fourteen days of incubation. The infective larvae of *Dirofilaria immitis* were found to be able to survive for a considerable period in the mosquito host. Of a batch of *Culex pipiens* mosquitoes infected on a filarial dog, the last positive mosquito dissected sixty-seven days later was found with two infective larvae moving about actively in its labium as well as one other living infective larva in its abdomen. The intensity of infestation of *Culex pipiens* mosquitoes in the Shanghai area was found to be affected by the abundance of microfilariae ingested by the mosquito at the time of infection. Of forty-eight positive *Culex pipiens* mosquitoes experimentally infected on a patient lightly infected with filariae, the average number of infective larvae per mosquito was 39, whereas of twenty-nine *Culex pipiens* mosquitoes experimentally infected on a patient heavily infected with filariae the average intensity of infestation was 144. As many as forty-three living infective larvae were found in a single *Culex pipiens* mosquito that had been allowed to feed only once on a patient heavily infected with filariae. *Anopheles punctipennis* was found experimentally to be a good carrier of the dog filaria, as the average number of filariae per mosquito was about 235. Some of the experimentally infected mosquitoes, which were found with infective filarial larvae of *Dirofilaria immitis* in their labia and abdomen, were used for these observations. Some *Anopheles punctipennis* mosquitoes infected about twenty-four days previously and found harboring infective *Dirofilaria immitis* larvae in their labia and abdomens were allowed to feed on a dog. Of the three infective mosquitoes in this batch which had bitten the dog, two were found to be still harboring some infective larvae in their abdomens, although all their labia were now negative for infective larvae. Two infective larvae were found remaining in the abdomen of one mosquito, while another still contained six infective larvae in its thorax and one in its abdomen. The third mosquito was found with one infective larva still in its thorax. These mosquitoes were still likely to be infective to dogs, as their supply of filarial larvae had not been exhausted by their first bite after the incubation period of their parasites had been completed. The ability of a mosquito to serve as a suitable host for a heavy infection of *Wuchereria Bancrofti* larvae may vary with the kind of mosquito, as indicated by Hicks. Many specimens of *Culex pipiens* heavily infected with matured larvae survived for a considerable length of time. An engorged *Culex pipiens* mosquito dissected on the third day after feeding on a filarial subject was found harboring four *Wuchereria Bancrofti* larvae of an early sausage form and twenty-three infective larvae. The infective larvae of this mosquito were doubtless filariae that were ingested during an earlier blood meal rather than filariae in the blood meal taken three days before the specimen was dissected. Those in the sausage form were likely to have been filariae taken along with the blood meal on the day the mosquito was captured. Multiple infections of a susceptible mosquito may thus increase its supply of parasites considerably. In mosquitoes with several broods of filarial larvae, infective larvae of an earlier brood which had not escaped from their mosquito host may be harbored along with those of a later brood.

- *Anatomic and Physiopathologic Study of Lung Infarcts of Embolic Origin Role of Vasomotor Nervous System J. Delarue, L. Justia Besançon and P. Bardin—p 681

Experimental Lung Infarcts of Embolic Origin.—Delarue and his co-workers studied experimental pulmonary embolism. At first they used enamel beads of from 1 to 8 mm. diameter injected into the external right jugular vein. After the dog had been anesthetized the vessel was dissected free for about 5 cm and the superior extremity ligated. It was opened for from 0.5 to 1 cm and the orifice maintained by a fine cannula, by means of which twenty beads having the maximum caliber of the vein could be introduced. The beads were pushed by the thumb to the retroclavicular junction of the jugular vein, after which the central end of the jugular was tied. All operations were performed aseptically. The animals were killed at varying intervals: immediately, fifteen minutes, thirty minutes, one hour, twenty-four hours, forty-eight hours, seven days, fifteen days, three weeks, one month, and three months later. The immediate result is an intense congestion of a large zone of pulmonary parenchyma. After some hours the lesion appears more circumscribed, while the diffuse congestion is less marked. Intra-alveolar hemorrhages become the predominant lesion. The typical hemorrhagic infarct is not present until after forty-eight hours. This is a massive and homogeneous bloody infiltration of one or more pulmonary lobes. Little by little after a dozen days the limits of the lesion become demarcated until it is surrounded by a practically intact pulmonary parenchyma. At the same time local hemolysis or sclerosis is observed appearing in the region of hemorrhagic infiltration. Further investigations showed that section of the left vagosympathetic trunk in the dog and unilateral section of the pneumogastric or of the sympathetic in the rabbit produce disseminated congestive pulmonary lesions, hemorrhages and edema. All these facts offer evidence in favor of the hypothesis that hemorrhagic infiltration of the pulmonary parenchyma is above all the effect of a sudden capillary vasodilatation of reflex nervous origin in a limited territory, followed by hemorrhage by erythrodiapedesis.

Early Nephritides of Scarlet Fever.—Lemerre studied scarlet fever patients from the standpoint of urea retention. He concluded that there is a frequent renal involvement coinciding with the eruptive phase of scarlet fever. Thus renal involvement is usually silent, and measurement of the blood urea is the only method of discovering it. It may be slight and indicated only by a moderate uremia. If more intense, it causes a more accentuated and persistent rise in blood urea. In this case it may be accompanied by extreme oliguria almost equivalent to scarlatinal anuria, which occurs later. In the course of early uremic nephritis, hypertension is always absent, albuminuria is rare, and if it exists it is late and transitory. Edema appears only under exceptional circumstances. These characters contrast with those of the nephritides of convalescence in which albuminuria, hematuria, edema and arterial hypertension are present, apparently unrelated to the level of blood urea. The prognosis of these early nephritides is benign. In the fatal cases that the author has observed the termination has been due more to the scarlet fever itself than to the renal involvement.

Dextrose Metabolism in Nephritis.—Rathery studied the free and protein-bound sugar of the blood plasma in more than 250 patients with nephritis. He distinguishes three groups of hyperproteinoglycemia—slight, around 1.2 Gm., average, from 1.2 to 2 Gm., and high, above 2 Gm. Urea determinations were also made on these patients. The question raised is whether hyperproteinoglycemia has a special prognostic significance different from that of uremia. It is certain that in severe cases the level of urea and protein-bound sugar take the same upward course, but it is not so in all cases. An average uremia with a normal protein-bound sugar indicates in general the existence of a serious renal lesion, but the prognosis is relatively favorable. Inversely, a protein-bound sugar relatively high with a practically normal blood urea level indicates that the kidney itself is not profoundly affected but that the organism is not defending itself well. Hyperproteinoglycemia persisting in the course of a chronic nephritis is in general a worse prognostic sign than the degree of uremia. No relations exist between the level of free sugar and protein bound sugar. Normal or below normal free sugar concurrent with elevated protein-bound sugar is frequently observed. There seems also to be no relation between hyperproteinoglycemia and renal acidosis. Systematic study of the variations in protein-bound sugar in the nephritic patient is a valuable aid in measuring the intensity of the metabolic disorder. It acquires for this purpose a special importance and a significance entirely different from that of elevated blood urea.

Early Diagnosis of Chorio-Epithelioma.—Brindeau and his co-workers studied systematically the luteinizing factor of the anterior pituitary-like principle present in the blood serum of women who had evacuated a mole. Twenty-three cases of mole without subsequent malignant condition and four followed by malignant conditions were studied. They believe that these observations allow the early and rapid diagnosis of postmolar chorio-epithelioma. They conclude that the disappearance of the gonadotropic hormone from the blood does not occur at a constant rate or follow a regular rhythm identical in all cases. The prolonged period of hormone elimination and the consequent persistence of a positive Zondek reaction does not necessarily indicate the malignant evolution of the molar rests. The authors' method is based on the curve of a series of regular titrations of the luteinizing factor of anterior pituitary-like principle made on the blood serum during the six or twelve weeks following expulsion of a mole. Ordinarily the amount present decreases progressively at varying rates. This conclusion is based on three facts: 1 The presence of a chorio-epithelioma is accompanied by the luteinizing factor. 2. The quantity of this factor secreted is in direct relation to the vitality and abundance of the plasmodial elements. 3 The rapid and precise titration of the factor is possible by using the rabbit. In the twenty-seven cases discussed, the four positive results were histologically verified. Finally, in the authors' experience, the reappearance of the hormone after its complete disappearance has never been observed.

Rare Forms of Osteomyelitis.—Meyer-Wildisen points out that osteomyelitis usually attacks the lower extremity, chiefly the femur, and that it is generally caused by *Staphylo-*

coccus pyogenes-aureus. This report shows that osteomyelitis may attack other bones and may be caused by other micro-organisms. He discusses three cases. In one patient the second metatarsal was involved, in another the proximal phalanx of the middle finger, and in the third the femur. In the latter case it appears probable that typhoid was the cause of the osteomyelitis. The patient had typhoid twenty-one years before this attack of osteomyelitis. During the period of convalescence from typhoid she had had severe pains in the right thigh, and these pains had recurred from time to time. The present attack of osteomyelitis developed following overexertion. The pus of the osteomyelitic abscess was free from typhoid bacilli and also from other micro-organisms. The author says that the pus has been known to be sterile in other cases in which typhoid is the cause. He considers this case a relapsing osteomyelitis of typhoid origin. Traumatic origin was evident in the case in which the osteomyelitis was localized in the finger, but no such cause could be detected in the case in which the metatarsal was involved. In this case further inquiry disclosed that several months before the onset of the suppuration in the foot the patient had had a varicella-like disorder. Since the vesicles of varicella are readily infected by the staphylococcus, it is assumed that the accidental infection of the impetiginous pustules was the cause of the osteomyelitis.

Yeast in Metabolism of Carbohydrates.—Barone reviews the literature on the action of yeast on the metabolism of carbohydrates and reports his results from the administration of fresh yeast to normal persons and diabetic patients. In both groups the author's results proved that fresh yeast has a hypoglycemic action if given by itself, a decreasing action on the hyperglycemia provoked by the administration of dextrose and galactose if given simultaneously with these sugars, and a remarkable although transient increasing action on the alcohol in the blood if given simultaneously with dextrose. The author concludes that his results justify further clinical investigations by giving yeast to diabetic patients with the aim of ascertaining its possible therapeutic applicability in the disease.

Encephalocele Case M Contestabile—p 352
Benign Angiomatous Tumors of Skeletal Muscles. G Zappalà—p 367

Bleeding Breast.—Bellini reports four cases of bleeding breast caused by an intracanalicular papilliferous fibro-adenoma. In the first case, an intracanalicular epithelioma degenerating into pericanalicular epithelioma in the second, and an intracanalicular hemorrhagic cystic epithelioma in the third. Biopsy or operation was not performed in the fourth case. The author says that the treatment should be based on the results of the biopsy without giving any importance to data of relative value, such as the duration of the development of the disease and the age of the patient, but having in mind the frequency with which bleeding breasts degenerate into precancer or cancer, he advises resorting to a total mastectomy with emptying of the axillary space in all suspected cases of cancerous degeneration.

*Partial Amputation of Cervix Uteri in Chronic Cervicitis E A Boero—p 48
Technic for Electrocardiograms J Comas—p 54

Partial Amputation of Cervix in Chronic Cervicitis.—Boero thinks that chronic cervicitis in women around 40 years of age is a prodrome in the development of cancer of the

cervix indicating the removal of the infected area. He uses a modification of the Sturmdorf operation, the original technic of which was illustrated in *THE JOURNAL*, Nov. 27, 1926, page 1802. In this modification he does not use the flap of a partial mucosa to cover the denuded area after removal of the pathologic tissues, and he makes a dissection at the commissures of the external orifice of the uterus. His technic is as follows: With the patient in the lithotomy position and under local or parametrial anesthesia, the cervix is exposed. The anterior and posterior lips of the cervix are grasped by two four-tooth forceps placed at the commissural line, and the cervix is pulled down toward the vulva. A Hegar dilator of the same caliber as that of the cervical canal is introduced through the canal down to the bottom of the uterus to keep the canal dilated during the operation. While traction is made on the cervix by the forceps and the dilator held in the left hand, a sharp and pointed bistoury is introduced at a point 2 or 3 mm within the healthy tissue and the entire glandular area surrounding the cervical canal is coned out. The cone excision extends up to the internal os. The incision leaves a conic cavity of normal muscle and conjunctive tissue. The surfaces of the cavity bleed slightly. The commissural points of the lips are then grasped with the same kind of forceps and wedge-shaped pieces of cervical tissue are removed. The superior and inferior lips are then folded by two lines of catgut sutures in each lip and the denuded surfaces are brought in apposition to form the new neck. A raw area that remains about the internal orifice after the operation deserves no attention, since it is spontaneously epithelialized shortly after. A packing of gauze impregnated with iodoform ends the operation. The new cervix, after the operation, looks like the opened bill of a duck, a few months later its shape improves and the orifice looks like that of a primiparous woman. The operation is not advisable in young women who desire children.

Differentiation of Active and Inactive Tuberculosis.—Investigations on the differential blood count following the Pirquet reaction conducted by Engel and Ockel and the studies of Bredeck on tuberculin and the blood differential count in the diagnosis and classification of tuberculosis induced Decker to give his attention to this problem. He adhered largely to the method employed by Bredeck, but he injected only 1 mg of old tuberculin and examined the blood picture shortly before and twenty-four and forty-eight hours after the injection. In order to reduce the errors, 500 leukocytes were counted in each cell count. An increase in the staff cells was disregarded unless it was at least 4 per cent in forty-eight hours, and in the case of lymphocytes 5 per cent was considered the minimum. Lesser changes were considered within the margin of error. The author made the test on fifty patients with demonstrated active tuberculosis, three patients with renal tuberculosis, fifty persons without tuberculosis and eighteen patients who formerly had had tuberculosis but in whom clinical examination now gave no indications of activity of the process. In all patients with active tuberculosis, the tuberculin injection was followed by an increase in the staff cells and the lymphocytes were decreased in twenty-nine, remained unchanged in seventeen and were increased in four. It is noteworthy that the staff cells were increased even in hopeless cases, in which the defense powers seemed to be exhausted. Two of the three patients with renal tuberculosis reacted with an increase in the staff cells, while in the third one there was only a reduction in lymphocytes. The fifty nontuberculous control persons disclosed no change in the staff cells after the tuberculin injection. The eighteen persons who had recovered from pulmonary

tuberculosis likewise had no change in the staff cells, while the number of lymphocytes remained unaltered in fourteen and was increased in the other four. The author reaches the conclusion that, if a patient with normal blood picture or with one that has shifted to the left, and for which no other explanation can be found, reacts to an intracutaneous injection of 1 mg of old tuberculin with an increase in the staff cells, this is an indication of the presence of active tuberculosis. A decrease in the lymphocytes probably has the same significance.

Leukocyte Count and Sedimentation Speed in Tuberculosis.—Leitner reports the results of comparative studies on the sedimentation speed of the erythrocytes and on the white blood picture in 137 cases. Of 109 patients with active tuberculosis, ninety-two, or 84.3 per cent, had a shifting to the left of the neutrophils, whereas this shifting to the left was lacking in seventeen cases, or 15.7 per cent. The sedimentation reaction was normal in thirty-five cases (32.1 per cent) and was increased in seventy-four (67.9 per cent). This shows that the sedimentation test failed more often than the white blood count. In ten patients who in the beginning had a normal sedimentation speed there was later an increase, so that in serial sedimentation tests the number of failures was reduced to twenty-five (22.8 per cent). Of twenty-six patients with inactive tuberculosis, only two showed an increased sedimentation speed and an altered blood picture (7.6 per cent). If, in addition to the neutrophils, the other cell types are considered, pathologic blood changes are demonstrable in a still higher percentage of cases of active tuberculosis. In some instances even the red blood picture may be valuable for the diagnosis (observation of the reticulocytes), but the behavior of the monocytes, eosinophils and lymphocytes is more important. The monocytes are always an indication that the tuberculous process has not yet come to rest but that the organism is still in the defense phase. The outcome of the defense is indicated by the status of the neutrophils or lymphocytes. Contrary to former opinions, eosinophilia is not a sign of cure but always a symptom of activity, for it occurs also in hyperallergic reactions. Moderate lymphocytosis does not necessarily signify a curative phase, but characteristic lymphopenia as a rule indicates severe, active tuberculosis. The subsequent lymphocytosis is favorable and indicates an improvement, usually a tendency to latency. Changes in the leukocytes, in the form of toxic granules or nuclear pyknosis, likewise are of some diagnostic significance. The diagnostic possibilities are further enhanced by combining the study of the blood picture with the tuberculin test. The author thinks that Schilling's blood count is more practical for clinical use than Arneith's count, the latter being too complicated. He recommends the combined use of the sedimentation test and the analysis of the blood picture.

- *Treatment of Rheumatic Disorders with Soaked Venom. A. Burkardt—p. 1159

Meinicke Clarification Reaction.—Koch states that in his clinic the Meinicke clarification reaction has been employed in approximately 36,000 cases. He thinks that the micromethod of the clarification reaction is valuable, for it is rapid. However, it has been known to fail, particularly in strongly positive serums, a factor to which Meinicke himself has called attention. This is not caused by a lack of sensitivity but rather by the great sensitivity, and Meinicke has advised the dilution of the serum with sodium chloride solution in such cases. The author found this unnecessary, because other reactions insured the diagnosis in these cases. In analyzing twenty-seven cases in which the Meinicke clarification reaction had failed he found that failure was most frequent in cases of congenital syphilis and in patients with the late forms of syphilis, especially with aortic syphilis and dementia paralytica. He advises that in these cases other serologic tests should be made in addition to the Meinicke clarification reaction. Since the withdrawal of a sufficient amount of blood may be difficult in nurslings,

the author thinks that puncture of the superior sagittal sinus by way of the large fontanel will yield a sufficient amount of blood, and he states that this intervention is comparatively simple.

Treatment of Rheumatic Disorders with Snake Venom.—Burkardt discusses the chemistry and toxicology of snake venoms and calls attention to former therapeutic experiences with snake venom, particularly in thrombopenia and in the control of pain in malignant tumors and in sciatica, neuralgias, tabes dorsalis and so on. In these conditions the chief advantage of venom therapy lies in the fact that it does away with the use of morphine, so that the patients have a better appetite and their physical and psychic resistance is better. Körbler noticed that an arthrosis of the hip joint improved considerably following the administration of snake venom and he assumed that the venom not only reduces the pain but also influences the metabolic processes. In view of these observations and after several years of experience with bee venom in the treatment of rheumatic disorders, the author decided to try snake venom in the hope of overcoming certain disadvantages of the use of bee venom. He thought that the possibility of using larger doses might improve the results and that with a less expensive product the venom therapy might become possible for a larger number of patients. He administered the venom by intracutaneous injection and was almost always able to counteract the pain in seventeen cases of sciatica and various forms of neuralgia. In secondary chronic articular rheumatism the results were not convincing, but then the number of cases was rather small. At any rate, in some cases with acute exacerbations with swelling, pain and reddishness of several joints three or four treatments were quite effective. In primary chronic arthropathy, improvement could be obtained in three fourths of the cases, the general condition, the joints and the sedimentation speed of the erythrocytes indicated improvement. In the gonorrheal and tuberculous arthritides, the articular swelling and the pains were considerably improved in eight of ten cases. Improvement was produced also in four cases of spondylitis. Even in degenerative arthroses the results were gratifying.

Corpus Luteum Hormone and Castration Hypophysis—Hohlweg demonstrates that the corpus luteum hormone does not prevent the development of castration changes in the anterior lobe of the hypophysis. His experiments were made on castrated female rats. The animals were given daily 540 micrograms of crystallized corpus luteum hormone (progesterone). This quantity is twice the daily dose for adult rabbits, but it did not prevent the development of the hypophyseal changes that are characteristic of castration.

Cerebrospinal Fluid in Whooping Cough—Bayer demonstrates that the cerebrospinal fluid shows pathologic changes in a relatively large number of children with whooping cough. These changes concern the pressure, the quantity, the number of cells, the quantity of protein, the mastic curve and the blood-cerebrospinal fluid barrier. These changes may be present and may be severe, even if there are no indications of nervous complications, they indicate pathologic changes in the meninges. It is difficult to find a satisfactory explanation for the changes in the cerebrospinal fluid, but it may be assumed that toxic influences are responsible, as in other infectious diseases. However, in whooping cough it is likely that certain mechanical factors likewise play a part. The author calls attention to the repeated pressure fluctuations in the cranium caused by the paroxysms of coughing. He was able to observe in a number of children an increase in the intracranial pressure during the attack of coughing and he found that the pressure of the cerebrospinal fluid increased by from two to three times

the original value. These increases in pressure are of short duration and probably are due chiefly to the venous stasis that develops during the attack of coughing. The pressure in the cerebrospinal fluid subsides again together with the venous stasis, that is, immediately after the attack of coughing. It is probable that these recurrent pressure fluctuations exert an unfavorable influence on the cells of the cerebral meninges and on those of the brain. The development of edemas can be explained on the basis of such mechanical influences. Moreover, the cells that have been impaired by mechanical influences are of course more sensitive to toxic influences.

Etiology of Tear of Interarticular Disk—Linde discusses whether the tear of the interarticular cartilage of the knee joint, which is a rather frequent complaint in miners, is always traumatic or whether it may be the final result of a wearing away of the cartilage, as the miner frequently has to work on bended knees. The author accepts the traumatic origin and points out that, if the wearing away was the cause of the tear, it should occur with considerable frequency not only in miners but also in other occupations that require working in the kneeling or squatting position. However, in many of these occupations other disturbances, such as bursitis, develop, but tearing of the interarticular cartilage is not associated with this. Therefore it seems logical that in the miner's occupation some other factor besides the kneeling must play a part in the development of the tears in the interarticular cartilage. The author thinks that the use of pneumatic tools plays an important part in the development of the tears, for the miner uses these tools either in the kneeling position or while his knees are partly bent. He shows how this may influence the menisci. He thinks that the development of impairments of the menisci in ski runners and mountaineers does not disprove the part played by the pneumatic tools in miners, for the concussions and vibrations to which the knees of mountaineers and ski runners are exposed under certain conditions largely resemble the concussions produced by pneumatic tools.

Craniocerebral Iontophoresis in Cerebral Disorders—Ehrenwald describes his method of craniocerebral iontophoresis. He saturates a piece of cloth or blotting paper, 15 by 7 cm. in size, with an urticariogenic substance (such as histamine or acetylcholine), puts under it a piece of lead or zinc foil of proper size and fastens it at the hair line on the forehead or the neck. Another metal foil with a dampened base serves as a cathode on the opposite side. The histamine was used in a concentration of 1:5,000. The galvanic current of from 4 to 5 milliamperes is passed through for about five minutes. The active substances exert their influence from the positive pole. With this treatment the author obtained favorable results in all forms of angiospastic circulatory disturbances of the brain, such as migraine, habitual anemic headaches of neurotic patients and some symptoms occurring in patients with hypertension (headache, vertigo and tinnitus).

Treatment of Exophthalmic Goiter with Large Doses of Vitamin A—Wendt says that several years ago Abelin found that experimental hyperthyroidism could be improved or entirely counteracted by a special diet with a high vitamin content. Later others found that vitamin A is a direct antagonist of the secretory product of the thyroid. The author tried vitamin A in the treatment of hyperthyroidism. The patients

were given three times daily 30 drops of a vitamin A concentrate obtained from fish livers. In three patients with exophthalmic goiter this treatment produced a considerable increase in weight and a reduction in the basal metabolism to almost normal values, and it seems to promise favorable results in two other cases of exophthalmic goiter. It appears that the vitamin A therapy is most effective in mild cases and in cases of average severity. Cases of exophthalmic goiter caused by iodine, which as a rule are not readily influenced, likewise seem to yield to this treatment.

Treatment of Malignant Tumors with Fractional Roentgen Irradiations—Chaoul points out that the superiority of radium therapy over roentgen therapy is not so much due to the character of the rays as to the manner of application. For this reason attempts have been made by Holthusen and others to devise a method of roentgen irradiation the action of which resembles that of radium rays. The author worked with a modified roentgen method that applies the rays to small fields. The focal skin distance is generally 5 cm., the tension 60 kilovolts and the filter 0.2 mm of copper. In this manner the depth dose is somewhat greater than is generally the case in radium contact irradiation, but the author sees in this an advantage of the treatment. He administers daily from 300 to 400 roentgens. The irradiation time is rather short, for, with a minute flow of from 100 to 150 roentgens, the 300 or 400 roentgens can be applied in about two minutes. The total dose varies between 4,000 and 8,000 roentgens. This amount is applied within a period of from two to four weeks. If in the course of the irradiations dark red erythemas develop, accompanied by a loosening of the epidermis, it is advisable to interrupt the irradiations. Generally the reactions after this form of short distance irradiation resemble those of Coutard's method. The modification of the tumor often becomes manifest in the course of the treatment, and, if this is the case, high doses may be dispensed with. Caution is necessary if the patient has previously been irradiated by some other method, because there is danger of necrosis. For the same reason the author rejects the combination of this short distance irradiation with some other form of roentgen irradiation. He considers the treatment indicated in the same cases in which contact or implantation radium therapy would be employed. So far the treatment has been used in 146 cases, among which were all forms of skin carcinomas and carcinomas of the lip, the oral cavity, the parotid, the breast and the rectum, the latter following resection of the coccyx and opening of the intestine. The author stresses the advantages of this treatment in cases in which it is impossible to obtain adequate amounts of radium.

Short Distance Irradiation in Gynecology—Schaefer administers x-rays from a short distance by means of a special x-ray tube that can be introduced into the body cavities. This tube is constructed like a Lenard tube, except that, instead of the thin window that allows the passage of cathode rays, this tube has thicker metal, which does not permit cathode rays to escape and serves as an anode. This tube in combination with suitable filters permits the localization of the rays on the tumor and the preservation of the normal tissues. The author stresses the following as the advantages of the treatment: 1 The skin is not impaired, because the rays are applied directly to the tumor. 2 As the result of the short focus distance and of the filter action the spatial dose is small and the surrounding healthy tissues (intestine and bladder) are not impaired. 3 The method makes possible a separate irradiation of the

parametrium with larger doses than were formerly possible. 4 In case of recurrence the method permits the application of large doses in patients in whom the skin would not tolerate large doses. The author employed the treatment especially in inoperable tumors of the cervix uteri. He usually introduces radium into the tumor, so that from 3,000 to 4,000 mg element hours is applied. Then he irradiates the small pelvis from the outside by means of an x-ray tube suggested by Martius, which insures an even distribution of the rays and preserves the tissues. Finally he applies a separate irradiation to the parametrium by means of the tube that can be introduced into body cavities. At a 5 cm. distance from the filter, from 2,000 to 2,500 roentgens is applied to the pelvic wall. In some patients the use of radium and the external irradiation were dispensed with and only the x-ray tube for use in body cavities was employed. It was found that the primary tumor was destroyed just as if radium had been used and that the mil trates in the parametrium disappeared completely. Nevertheless, the author thinks that it is advisable to combine internal with external irradiation.

Continuous Roentgen Irradiation of Cancer—The roentgen method suggested by Palmieri permits the simultaneous irradiation of several patients at a distance of from 4 to 5 meters. The irradiation intensity is slight and can be compared with that of radium therapy. The main purpose of the method is to imitate radium therapy in its time factor, as the author thinks that the chief advantage of radium therapy is its selectivity, which is due to the fact that the radium is employed continuously for long periods. He points out that his "superteleoroentgentherapy" somewhat resembles the so-called telepanirradiation employed by Heublein in New York. He describes his apparatus, which permits the simultaneous application of x-rays to four patients, the cabins in which the patients are placed during the irradiation and the arrangement and measurement of the doses, the marking off of the fields and the method of filtration. The treatment was employed in cancers of the oral cavity, the upper air passages, the esophagus, the stomach, the lung, the uterus and the skin. In some instances the results were gratifying but complete cure was not effected in any of the cases.

Modification of Epinephrine Hyperglycemia—In persons without metabolic disturbances, Boller and Makrycostas investigated to what extent certain diets or insulinization during the preliminary period influence epinephrine hyperglycemia. They state that the blood sugar curve following an injection of epinephrine is not changed by the diet given during the period preceding the epinephrine injection. However, chronic insulinization during the preliminary period increases considerably the action of epinephrine on the blood sugar. It was found in several cases that this increase is most noticeable when insulinization is done while the person receives a diet deficient in carbohydrates. An epinephrine injection during a dextrose tolerance test demonstrates that the increased permeability of the liver for sugar following a diet deficient in carbohydrates or following insulinization can be throttled.

Dissociated Bile Retention—Mitow says that Lemerre and Brulé in 1910 called attention to the so-called dissociated bile retention, which was ascribed to the fact that the hepatic cells are not always impaired in the same manner, in that in some instances they retain all bile constituents, in others only the bile salts and in others only the bile pigments. In the author's clinic it was assumed that the problem could be cleared up if the duodenal juice was examined in the doubtful cases. If the theory of Lemerre and Brulé is correct, it might be expected that, if the bile salts are absent from the urine of patients with jaundice, they should be present in the duodenal

juice, in which they are carried with the bile. If there is no dissociation, if the bile salts are destroyed somewhere in the organism or are retained, or if they are not even formed, they will not be found in the duodenal juice. The author studied this problem on patients with various types of jaundice. He reaches the conclusion that Lemerle and Brule were right when they spoke of a dissociated bile retention.

*Total Calcium Content of Blood in Normal and Spasmophilic Children
S. Siwe—p. 368

Erythema Nodosum in Scarlet Fever—Morn stresses that during childhood cases of erythema nodosum may appear that have no connection with tuberculosis. He reports a case that developed during scarlet fever and in which repeated tuberculin reactions were negative. He emphasizes that the notion of erythema nodosum of childhood as a sure symptom of tuberculosis should be abandoned. Erythema nodosum in scarlet fever nearly always appears during the third or fourth week, that is, during the same critical period during which such complications as late lymphadenitis, hemorrhagic nephritis, secondary anginas, the true scarlet fever relapse, late synovitis and late endocarditis develop. Schick considered these manifold "after diseases" of uniform pathogenesis and the manifestation of a "period of specific predisposition."

Calcium of Blood in Spasmophilic Children—Siwe studied the total calcium content in normal and spasmophilic children. He determined the calcium values of blood specimens withdrawn in the morning and in the evening. In normal cases he found regular curves at a high level. In spasmophilic cases the curves indicate considerable instability, there are great differences between the morning and evening values and there are irregular increases and decreases in the total values. In patients with spasmophilia who have convulsions the calcium level is usually rather low, but the sudden changes are more characteristic than the low values. In the patients in whom convulsions developed during the time they were under observation, considerable reductions always appeared suddenly followed by more or less pronounced increases in the total calcium values. The author thinks that these sudden fluctuations explain the so-called exceptional cases in which high calcium values are observed during spasmophilic convulsions, for the calcium value in such cases depends entirely on the time of withdrawal of the blood specimen. No other factor is necessary to explain these cases. Although convulsions seem to develop at the time of considerable reductions in the calcium content, they do not necessarily or regularly develop at these times. The author concludes that the determination of the total calcium content of the serum can never definitely exclude spasmophilia, even if the result indicates practically normal values.

Venesection in Treatment of Erythremia—According to Reimann and Breuer it is generally believed that venesection is of only slight value in the treatment of erythremia. They cite reports which indicate that, although venesection has been resorted to in erythremia, it has been rarely made use of in a systematic and well planned manner. They were induced to try systematic venesection in the treatment of erythremia by observations in a case of erythremia in which severe hemorrhages resulted in anemia. They employed venesection in the

treatment of seven cases of true erythremia. As a rule the venesections were made twice weekly, from 300 to 400 cc being withdrawn each time. This treatment was continued for several weeks. During this time the patients were kept under constant control as regards the blood status as well as the general condition. When the hemoglobin had decreased to from 80 to 90 per cent the venesections were discontinued, but the patient was still kept under clinical and hematologic control. The withdrawal of the relatively large quantities of blood was nearly always well tolerated. After the third or fourth venesection the patients generally reported considerable improvement. The external characteristics of erythremia, such as redness of the skin and of the mucous membranes, improved and the subjective complaints in the form of headaches, rushing of the blood to the head, vertigo, tinnitus aurium, fainting, palpitation of the heart and others disappeared. The authors think that the success of the venesection is chiefly due to the fact that the substances, such as iron, which the organism requires for blood formation, are removed to a considerable extent and the pathologically increased blood formation is inhibited. The vascular system is relieved of its surplus load, the overfilling of the organs with blood is reduced and their normal functioning is thus improved. After the venesection treatment, a tendency to remission frequently becomes noticeable and this improves the action of the blood withdrawal. The effects of the venesection therapy persisted for approximately two years. In comparing the results of venesection with other therapeutic methods that are successfully employed in erythremia, particularly with roentgen therapy and the use of phenylhydrazine, the authors found that venesection is equivalent to these.

Complete Sinus Block with Branch Block in Myocarditis—Marzahn reports the history of a patient in whom a rare combination of cardiac defects occurred. In the course of a subacute myocarditis following influenza, a complete sinus block occurred with a branch block of the right side. The patient died from acute pulmonary edema. The auricular waves were absent in all three leads of the patient's electrocardiogram, which indicated an atrioventricular automatism of relatively high frequency. The author assumes that juxtasinusal, supranodal inflammatory degenerative changes were the eliciting cause of the abnormal stimulus formation in the atrioventricular node, for on the basis of the anatomic observations, particularly in view of the multiple necroses that interspersed the entire bundle, such changes seem probable. Inflammatory changes in the region of the sinus node must have interrupted the conduction between the sinus node and the auricle. The branch block is sufficiently explained by the necroses and the indurations.

Spontaneous Hypoglycemia—Schur and Taubenhaus show that the symptoms of spontaneous hypoglycemia resemble largely those of insulin shock. There may be slight discomfort, a feeling of hunger, profuse sweating and tremor, or coma and convulsions. The authors mention three conditions that may produce spontaneous hypoglycemia: (1) increased insulin formation resulting either from a quantitative increase in the islands of Langerhans or from a hyperfunction of these islands; (2) a disturbance in the counterregulation by hormones; and (3) a disturbance in the mobilization of the glycogen. They concede that there are a number of cases in which nothing can be found that would explain the attacks of hypoglycemia. Formerly the treatment of hypoglycemia was largely limited to the attempt to prevent the reduction in carbohydrates by the frequent administration of small amounts of carbohydrates. The single administration of large quantities of carbohydrates was avoided so as to prevent hyperglycemic attacks. The authors admit that the administration of small amounts of carbohydrates is only a symptomatic treatment which does not counteract the cause of the disorder, but they think that this treatment is sufficient for the milder cases. They say that the surgical treatment, which was first suggested by American authors, should be resorted to when an adenoma or a carcinoma of the islands of Langerhans exists or when there are inflammatory disorders in the biliary passages. The surgical intervention itself, as far as it concerns the pancreas, should be limited to the removal of the tumor.

The authors consider the resection of normal portions of the pancreas inadvisable. They cite a case in which they opened the abdomen in the belief that an insular adenoma existed, but, when no neoplasm was found, the abdomen was closed again. It was found that after this laparotomy the attacks of hypoglycemia ceased. The authors are unable to explain this peculiar effect but point out that the result of this laparotomy is practically the same as that achieved by resection of portions of the pancreas. They report a second case in which surgical correction of disorders of the biliary tract resulted in a disappearance of the attacks of hypoglycemia.

- Contribution to Jedlička's Surgical Method in Case of Pancreatic Cysts E Polák —p 1641
- Bleeding Jejunal Varices W Latten —p 1643

Nonspecific Chronic Epididymitis—Jordans points out that the majority of authors designate the gonorrheal, syphilitic and tuberculous forms of epididymitis as specific and apply the term nonspecific to all other forms of epididymitis. Many clinicians are of the opinion that the nonspecific epididymitis, as a rule, takes a chronic course. The author says that the surgical specimens which are sent to a pathologic institute for examination are nearly always from chronic or at least from subacute cases. He made studies in seventy-nine cases. Practically all age groups were represented in this material and he was unable to corroborate the opinion of a higher incidence of nonspecific epididymitis in the age group that follows puberty. He says that many investigators consider a urethrogenic and a metastatic pathogenesis but reject a purely traumatic origin. In cases in which an involvement of the spermatic cord can be demonstrated, urethrogenic continuous inflammation is generally assumed. However, involvement of the spermatic cord is often missing and in such cases some authors are inclined to assume a metastatic infection, while the majority believe that the origin is likewise urethrogenic. The author points out that mild forms of inflammation are readily overlooked in the specimens and are discernible only if microscopic inspection is made. Thus there arises the question whether cases of deferentitis may not be overlooked when the changes are slight. The author decided to examine the spermatic cords in the twenty cases of nonspecific epididymitis in which material was available. He detected a deferentitis of intracanalicular origin in eighteen of these cases, which again indicates a urethrogenic pathogenesis. The microscopic examination of seventy-nine surgically removed epididymides disclosed that nonspecific chronic epididymitis is localized particularly in the caudal portion of the epididymis and that it develops by the canalicular route. The author discusses the differentiation of nonspecific epididymitis from the tuberculous and the gonorrheal form.

Does Anemia Exist in the New-Born in Placenta Praevia?—The observation that the infants of mothers with placenta praevia have an anemic appearance induced Heising to compare the hemograms of these with the hemograms of normal new-born infants. He detected an anemia in eight of twenty-seven new-born infants from mothers with placenta praevia. In the most severe case of anemia the hemoglobin value was approximately 52 per cent below the average for the normal new-born, and the erythrocytes 45 per cent below the normal. The author points out that his observations corroborate the opinion expressed by Stoeckel and Zangemeister to the effect that in placenta praevia not only does the mother bleed profusely but also the infant may bleed.

- Traumatic Pneumothorax on Basis of Rupture of Lung H C Wennevold —p 770

Gaucher's Disease—Kveim has found thirty four cases of this disease in the literature. In his three personal cases, in a sister and two brothers aged 23, 28 and 26, there were considerable enlargement of the liver and spleen, leukopenia and thrombopenia, an increased sedimentation reaction, a tendency to bleeding, partly with subperiosteal hemorrhages, marked petechiae with consequent hemochromatosis, especially of the lower extremities, and brown coloration of the skin, mostly of the uncovered parts of the body. In the young woman pronounced changes in the bones also appeared, with typical wine bottle shape, chloasma-like spots on the face and yellow spots in the sclerae, and histologic examination of the bone marrow revealed the characteristic picture of Gaucher's cells. In this case a hitherto undescribed symptom also was present, namely, an almost black coloration of the instep and the leg almost up to the knees, directly dependent, the author avers, on the hemorrhagic diathesis, the special localization being due to mechanical and static reasons.

Fate of Eclampsia Patients—Of sixty-one cases of eclampsia in forty-eight patients, nine were without symptoms. Of the fifty-two remaining cases, thirty were complicated with recurring intoxication of pregnancy (eighteen with albuminuria, five with eclampsia, seven with eclampsia), grave in fourteen cases. Premature detachment of the placenta occurred in three instances the fatal case representing the only death in the material. Of forty-nine of the offspring, thirty-six (twenty eight mature) were alive and viable and eleven (one mature, seven viable) were stillborn, most of them macerated. Kjelland Mørde emphasizes that, while the question of interrupting the new pregnancy must be decided for each individual case, interruption is usually not necessary.

Poisoning with Blue Rocket Larkspur—Jakobsen says that the case resembled intoxication with an aconite alkaloid. The active substance was probably the alkaloid delphinine. He ascribes the comparatively mild effect to the use of extract of the root of the rocket larkspur instead of the seeds, which contain the main quantity of the alkaloid. Treatment was the same as for intoxication with aconite.

Angiomatosis of Brain and Trigeminal Region—In Schjeltz's case of epilepsy, the first symptoms set in before the sixth month of life. The patient, a man aged 44, had a vascular nevus of the face, the extent of which corresponds approximately to that of the first branch of the trigeminal nerve on the right side. The roentgenogram of the head shows numerous gyroid form calcified lesions, partly with double contours, their seat corresponding to the right lobe of the occiput. The author states that the combination of vascular nevus of the trigeminal region, telangiectasis of the pial vessels and glo-angiomatosis of the brain with debility or epilepsy (most often contralateral jacksonian epilepsy), or with both, is a special syndrome first clinically described in 1879 by Sturge. As the hemangiomas have a tendency to calcification, they become visible in the roentgenogram. He has collected eighty-six cases from the literature. Of the total eighty-seven cases, fifty-eight have been verified at necropsy, roentgenologically or operatively. The time of the appearance of the first symptom is known in sixty cases in forty this was at the age of 1 year or earlier, in twelve between 1 and 10, and in eight cases later than 10. Of seventy-six patients, fifty-three were men and twenty five women. The pathologic anatomy is reviewed with especial reference to Volland and Krabbe, who show that the calcifications lie in the cerebral cortex not in the pia mater.

CHRONIC SUBDURAL HEMATOMA

FRANCIS C. GRANT, MD
PHILADELPHIA

In this country the interest in chronic subdural hemorrhage was aroused by the report of Putnam and Cushing¹ in 1925. Curiously enough, at that time these authors could report but six cases from the Peter Bent Brigham Hospital records, although a very large amount of neurosurgical material passed through this clinic. Furthermore, in their careful review of the literature a bare half dozen American articles on this subject were available. Again, when in 1927 I² reported three instances of this condition from the Neurosurgical Clinic of the University Hospital, a cursory examination of its records failed to show any similar cases prior to this date. But when Munro³ in 1934 reviewed the literature for the past ten years on this subject, twenty-six articles were available from the American literature, eight appearing between 1926 and 1930 and sixteen since 1930. I do not believe that chronic subdural hematomas are becoming a more frequent sequela of head injuries. Cranial trauma is unquestionably increasing, owing to a speeding up of transportation due to good roads and the automobile, but the type of trauma following accidents from this source is of the more violent type, which does not usually produce this variety of lesion. As neurosurgical clinics become more widely established throughout the country, however, these cases find their way to them are recognized and are treated by surgical methods.

That chronic subdural hemorrhage should have remained an obscure condition is curious, for in 1914 Trotter⁴ reported five cases and described the type of injury and the mechanism whereby the hemorrhage occurred. He felt that bleeding resulted from a rupture of the short veins running from the cortex to the longitudinal sinus. These veins are straight and extend unsupported across the subdural space at right angles to the cortex and sinus. But little displacement of the brain in the anteroposterior plane of the head would be necessary to stretch them to the point of rupture. The falx divides the cerebral cavity in half from in front backward, checking lateral cerebral movement. But violence applied in the anteroposterior plane could

produce sufficient displacement of the cerebral mass to tear these veins. Brodie⁵ has recently emphasized this point.

In my series of sixteen cases, the head was struck in ten in either the frontal or the occipital region. But other veins run across the subdural space from the lateral sinus to the cortex and from the dura to the cortex over its convex surface. Rand⁶ reports three of seven cases in which he found such a vein thrombosed within the clot and hence a possible source of the hemorrhage. In one of my series a vein lay down in the temporoparietal region leading from the lateral sinus to the cortex was found torn loose and embedded in the clot. Munro³ records a similar case. That these subdural clots are so frequently bilateral suggests the importance of violence applied in the anteroposterior plane of the skull, for only in this way could veins on two sides of the falx be ruptured simultaneously.

Gardner⁷ has offered a thoroughly acceptable explanation for increase in the size of the clot after the original hemorrhage has ceased. Based on experimental study, he believes that hemorrhage, possibly slight in amount, may follow the original trauma. This hemorrhage lies in the subdural space and as Putnam has so well shown, becomes rapidly surrounded by a layer of mesothelial cells. On the dural side this mesothelial lining becomes thickened, and large mesothelial-lined vascular spaces form beneath the dura. These spaces seem to anastomose with one another and with adjacent newly formed capillaries. Gardner is of the opinion that the center of the clot is poorly vascularized and breaks down and liquefies into fluid rich in proteins. The thin mesothelial wall about the clot against the arachnoid acts as an osmotic membrane sucking cerebrospinal fluid into the sac. Thus slow, steady expansion occurs. Munro³ helps to confirm this theory by reporting figures on the protein content of the fluid obtained from these hematomas. He finds that the amount of protein is greatest between the fifteenth and the twenty-first day after injury, with a rapid fall thereafter until about the twenty-seventh day. From this time on the fall in protein content is gradual. Although he admits that the cases from which these figures are obtained are too few to be finally conclusive in detail, he feels that it is a fair assumption that they indicate breakdown and liquefaction with dilution of the contents of the sac by osmosis of cerebrospinal fluid.

This theory will account for those cases and they are by far the more numerous, in which the hematoma is made up of a brownish fluid surrounded by a thin

wall of heavy black clot. In all my sixteen cases and in twenty-nine of the forty cases recorded by Jelsma⁸ the center of the clot had liquefied. It will not account for those cases in which a solid clot is discovered. However, from reviewing the literature the impression is obtained that when this condition is encountered the history of the case is of shorter duration than when fluid and clot are discovered. Possibly sufficient time has not elapsed for liquefaction to occur. Furthermore, Gardner's theory of slow expansion of the cystic clot by osmotic increase in its fluid content fits in accurately with the clinical course that these cases run.

The injury is very frequently followed by a period of longer or shorter duration during which no evidence of an intracranial lesion can be noted. Then slowly and insidiously this develops, often with short periods of mental clouding or headache, which disappear only to recur. With each recurrence there is a slight but definite increase in symptoms, the interval between these bouts of headache or mental dullness becomes shorter and then rather abruptly obvious signs of cortical irritation appear as a convulsion or a hemiparesis, accompanied by marked increase in headache and definite clouding of consciousness. From the history, many of these subdural clots develop over periods of weeks or months and it is difficult to attribute such slowly progressive symptoms to a continuous or even an intermittent hemorrhage from a torn vein. Assuredly in other parts of the body venous bleeding is promptly checked by clot formation and does not recur.

Hematomas of this type occur with greatest frequency over the cerebral hemispheres. On rare occasions the hematomas may be subtentorial, although under these circumstances a laceration or contusion of the brain is usually the source of hemorrhage. In from 20 to 30 per cent of cases the hemorrhage is bilateral, a fact which must be kept in mind constantly. Any age may be affected, although young men predominate because they are more likely to receive head trauma. Peet and Kahn⁹ report a series of cases in infants.

Alcoholism seems to be a definite factor, although whether this is due to the fact that alcoholism leads to head injury or to some irritating effect of the alcohol on the subdural space is far from certain.

This report is based on sixteen cases of chronic subdural hemorrhage verified at operation or at autopsy. In none of them was an accompanying contusion or laceration of the brain the cause of the hemorrhage. In all there seemed to be an internal as well as an external limiting membrane enclosing a chocolate colored clot and a brownish fluid. Thus in all of them sufficient time had elapsed for liquefaction and capsule formation to occur. They fall, therefore, into groups 4 and 5, as recently described by Leary.¹⁰

The diagnosis in these cases depends on how recent and how clean cut the history of injury may be. If the clinical picture develops as a direct consequence of cranial trauma a definite conclusion that a subdural hematoma has formed may often easily be reached. But again the trauma may have been so mild that to attribute to it the development of such marked symptoms after so long a period seems ridiculous. In this series five patients were never unconscious at any time, five lost consciousness only momentarily, while none

of the remaining six were unconscious for more than ten minutes. The importance, therefore, of any injury no matter how trivial, particularly if violence has occurred in the anteroposterior plane of the head, should be stressed. In one patient even after careful questioning no definite history of injury could be discovered, however, his symptoms had been present for at least two years, a long time to remember as slight an injury as can apparently result in a hematoma.

Bowen¹¹ calls attention to the "lucid interval" existing between the injury and the development of unconsciousness and the "latent interval" or period between the trauma and the appearance of the first symptom suggesting an intracranial condition. These two intervals overlap, and, in my experience, which seemed different from Bowen's, the lucid interval is longer than the latent. None of my patients lapsed into complete unconsciousness without other evidence of cortical irritation having previously developed. Nor did I observe any definite feature in the development of symptoms which is of particular importance in differentiating between a hematoma and any other intracranial mass lesion, as tumor or abscess.

Trotter⁴ speaks of the insidious mental changes and recurring bouts of mental dullness, each slightly more severe until rather abruptly semistupor or stupor develops. All my patients complained of headache, fourteen had definite slowing in the mental reactions, but only two were entirely unconscious. Six are noted as having been lethargic, even semistuporous, and two as stuporous. If any one characteristic in this group was to be singled out as of diagnostic importance, stress might be laid on the uncertainty and variability of the neurologic symptoms. But if an equal number of cases of brain tumor or abscess were carefully compared with this group of hematomas, it is far from certain that the difficulties in diagnosis and localization would vary in any particular degree. What is surprising, however, in retrospect, is that an intracranial lesion can reach the size so often attained by these hematomas, frequently extending from the frontal to the occipital pole, and compressing a hemisphere inward for 3 to 4 cm from the dura, and produce such surprisingly indefinite symptoms. Again, with lesions as massive as those so commonly encountered, more concrete evidence of intracranial pressure might confidently be expected. However, but three patients of this series had definite choking of the disks, and of the ten in which lumbar puncture was performed the pressure was elevated in but three. Bloody or xanthochromic fluid was found on four occasions. Kaplan¹² has recently reiterated the importance of a unilateral dilatation of the pupil in determining the site of the hemorrhage. The dilated pupil lay on the side of the hemorrhage in five of my cases and contralateral in three. In one instance both pupils were dilated.

Two important facts stand out in the survey of this small group of cases. In six cases the neurologic signs pointed to involvement of the opposite side of the brain to that actually involved. In other words, in over one third of these patients the hemorrhage and the hemiparesis were on the same side. Second, on three occasions the hemorrhage was bilateral. So that whether the diagnosis is made preoperatively or the subdural clot is an unexpected finding, both hemispheres

should always be explored. In the five cases just mentioned, exploration was done on the wrong side in two, with subsequent fatality and confirmation at autopsy. In the other three patients bitter experience led to bilateral investigation and eventual recovery.

The proper treatment for chronic subdural hemorrhage is exposure and removal of the clot. A subtemporal decompression or osteoplastic flap was fashioned over the suspected hemisphere and used to evacuate the clot until 1932, when Fleming and Jones¹³ and McKenzie¹⁴ suggested that simple trephines placed anteriorly and posteriorly over the vault with drainage of the fluid in the cyst without removal of the capsule were sufficient to cure this condition. Frazier¹⁵ has recently reported success with this simpler method of attack in five of six cases. In the present series, six patients were operated on through an osteoplastic flap without any mortality. In one instance bilateral subtemporal decompression was carried out with recovery. Among the eight cases in which simple trephines and evacuation of the clot was employed, four patients recovered and four died. On but one occasion among the four mortalities could the blame be laid to the method. In this case the clot was more solid than fluid. A second operation was necessary to complete evacuation and from this the mortality occurred. A second patient died from lung abscess and pneumonia following apparently successful evacuation of the clot through two trephine openings. Two patients succumbed because of improper lateralization of the lesion. The trephine holes were made over that cerebral hemisphere which the scanty neurologic signs suggested as the site of the hemorrhage. Autopsy showed the hematoma to be on the opposite side.

My own experience and opinion lean toward the use of a small osteoplastic flap, unless the patient's condition definitely contraindicates it. I feel that in this way, with little or no increase in operative hazard, complete evacuation of the clot with removal of the membrane can be accomplished. The arguments against the use of an osteoplastic flap are the greater length of time necessary, with loss of more blood and more likelihood of postoperative shock, the difficulty of obtaining perfect hemostasis after complete removal of clot and membranes, and the great frequency with which bilateral hematomas are discovered, requiring the added risk of a second craniotomy. I believe that bilateral trephines should always be made, and if the clot is found to be unilateral I turn down a flap on that side. If the clot is bilateral it is sufficient to rely on simple trephine drainage, but, if unilateral, safety and satisfaction compel me to perform an osteoplastic flap. Then complete removal of clot and membrane can be carried through. It is more certain that recurrence will not take place and the expansion of the brain into the area occupied by the clot can be more easily determined. In either operative procedure, a drain should be left within the dura for from twenty-four to forty-eight hours. The increased bleeding following an osteoplastic flap and removal of the clot occurs mostly from the dura. If the dura is cut all the way round turned over and resutured, all oozing from its surface will promptly cease.

McKenzie¹⁴ has recently made a valuable suggestion which overcomes one of the objections to the simple trephine for hematoma. At times, after evacuation of the fluid contents of the clot, the brain does not expand to fill in the cavity. He has found this to be due to that part of the cyst wall which is adherent to the arachnoid acting as a tight band and compressing the cortex. The operator can reach in carefully through the trephine opening, seize and tear this membrane, and thus allow the brain to pulsate outward and assume its normal position.

Another advantage of the osteoplastic flap is that it affords room for decompression. Putnam, Munro³ and others have called attention to edema of the brain due to release of tension following evacuation of the clot as a cause for mortality. While this has occurred in but one case in this series, and in this could fortunately be controlled, nevertheless a better chance for recovery under these conditions would result if a larger flap had been elevated than if simple trephines had been used.

SUMMARY

1 In sixteen cases of chronic subdural hemorrhage there were five deaths, four of which were postoperative.

Summary of Data in Sixteen Cases of Subdural Hematoma

16 Cases	
13 males 3 females	Average age 36
11 patients recovered, 5 died	
16 operative cases	
11 patients recovered 4 died.	
Operative Procedures	
Osteoplastic flap	recovered 6, died 0
Subtemporal decompression	recovered 1, died 0
Bilateral trephines	recovered 2, died 2 (hemorrhage bilateral 3)
Unilateral trephines	recovered 2, died 2
14 cases with history of injury	in 8 cases discovered only after operation
1 case with no known injury	
Severity of Injury	
Not unconscious	5
Briefly unconscious	6
Unconscious 5 minutes or more	5
Time from injury to onset of symptoms	average 5 weeks
Time from onset of symptoms to operation	average 2 weeks
Symptoms	
Headache	11
Stuporous	10
Hemiparesis	11 (5 instances in limbs ipsilateral to hemorrhage)
Unilateral pupillary dilatation	7
Ipsilateral to hemorrhage	5
Contralateral to hemorrhage	3
Facial weakness	7
Ipsilateral to hemorrhage	4
Pulse rate definitely retarded	8
Choked disk	3
Convulsions	1

2 A very slight cranial injury can produce a hematoma. The neurologic evidence of its presence may be extremely vague and misleading although headache and lethargy are always pronounced.

3 The uncertainty of the neurologic signs, the frequency with which the hemorrhage and the clinical evidence are ipsilateral, and the relatively large percentage of cases in which bilateral subdural hemorrhages occur all emphasize the importance of exploring over both cerebral hemispheres in every case.

4 Exploration can be carried out through two trephine openings placed anteriorly and posteriorly over each hemisphere or by an osteoplastic flap. The general condition of the patient should determine the choice of operations. Drainage should always be instituted after evacuation of the hemorrhage.

ABSTRACT OF DISCUSSION

DR. TRACY J. PUTNAM, Boston Dr Grant has emphasized that a subdural hematoma may follow an extremely mild injury but that no history of injury may be obtainable. I believe that he does not necessarily mean that it cannot follow a severe injury but only that the injury need not be very severe. It seldom follows an extremely severe injury, and I have sometimes wondered whether that was to be explained by the fact that an injury severe enough to cause edema of the brain may cause a tamponing of a torn vein and so prevent hemorrhage. Dr Grant has referred to Dr Gardner's explanation of the early increase in size of the collection of blood due apparently to the breaking down of the protein molecules into smaller molecules, which increases the osmotic pressure. It seems to me that it is necessary also to account for the late increase in size which apparently occurs in some instances long after the increase in molecular concentration of the cyst fluid must have ceased. This is perhaps explained by the fact that man has an upright posture and a negative pressure within the skull and that a hematoma elsewhere in the body may decrease in size as the result of bandaging and compression and, contrariwise, that the cupping which the negative pressure within the skull affords may cause an increase in size in granulation tissue. Perhaps that is why the capillaries are as enormous as they are seen to be and why hemorrhages occur. It has become my custom to rely more and more on burr holes to establish the diagnosis. It has become my custom to place the burr holes just at the origin of the temporal muscle, and I believe that this allows more certainty of locating the collection of blood than if the holes were made nearer the vertex. Unquestionably there are cases in which the entire contents of the sac can be evacuated through a single burr hole, there are others in which a subtemporal decompression will suffice, and there are others in which a flap operation will have to be done. I fail to see any advantage in two burr holes over a decompression and I believe that a small decompressive opening is more rapidly carried out. I think one should rely on one's judgment in the individual case. It has been very striking to me that, in spite of the fact that this should be a benign condition, it has a very high mortality in the cases reported in the literature. I think that perhaps the diagnosis is made more promptly now, and operation is more rationally conceived and carried out.

DR. W. JAMES GARDNER, Cleveland Of twenty-two cases eighteen were seen during a period of four years and they represented about 4 per cent of the expanding intracranial lesions seen during that time. Two-thirds of the patients were more than 40 years of age. It is inconceivable that cranial trauma is twice as frequent after the age of 40 as before this age. I feel that the explanation of this increase is that with increasing age there is increasing fragility of the cerebral veins so that they tear more readily. In this series the cases were all of long standing. In the youngest patient five weeks elapsed from the time of accident to the time of operation, and the longest interval was thirty-three weeks. The trauma in every case was mild. In none was fracture of the skull demonstrable. Only six patients were unconscious as a result of their injury, and only three of these were unconscious for more than two or three minutes. The most frequent accident was a fall on the ice, the occiput striking on the pavement. The latent interval between the time of the trauma and the onset of pressure symptoms averaged 3.6 weeks, and the average interval between the accident and operation was 12.5 weeks. The most frequent symptoms were headache and disturbances in the intellectual sphere, which were present in nineteen cases. I think one very important diagnostic point is the fact that the somnolence and stupor are out of all proportion to the degree of intracranial pressure in the majority of cases. When a patient shows signs of increased intracranial pressure, with a normal spinal pressure, one should always be alert as to the possibility of subdural hemorrhage. In eight cases the neurologic signs pointed toward the side of the lesion, in five there were no localizing signs, in five the signs pointed toward the wrong side of the brain and in four unilateral lesions the neurologic signs indicated bilateral damage. The frequent incidence of homolateral

signs in these cases is due to the dislocation of the brain, with resultant pressure on the cerebral peduncle by the incisure of the tentorium. Two patients showed a homolateral homonymous field defect. I presume that it is also due to the dislocation of the brain with resulting pressure of the lateral geniculate body against the incisure. Two patients died with the condition undiagnosed. Of the twenty patients operated on, two died and eighteen recovered. In fifteen of the cases the symptomatic recovery was complete. This, therefore, represents a most benign, expanding intracranial lesion, and one should be ever alert as to the possibility of this lesion being present, because the patient's life can usually be saved if the surgeon is fortunate enough to get him before he is moribund. Eight patients, two of whom died, were treated by a single drill hole located about midway between the sagittal suture and the ear. The two who died had bilateral involvement.

DR. PETER BASSOE, Chicago I will mention one case that I think may be of some interest. A farmer in a fall struck the left side of the head on an iron roller. An hour later he staggered into the house and was quite stupid, but he recuperated. He kept on working, complaining of headache every day. He had to give up in about a month. He had dizzy spells, his headache was terrible, and he became more and more stupid. Headache and stupor were the main symptoms. I saw him in consultation. His physicians were in doubt about the diagnosis because the family said that the man had been queer. He was 56 years old, and eight or ten months previously he had married a woman who was pregnant, although he knew that somebody else was responsible for the pregnancy. They thought that there had been something wrong with his brain before the injury. When I saw him he was in a stupor. I could not examine his sensation. He had a slight choked disk on the left side and a partial right hemiplegia. His pulse rate was from 45 to 50. I made the mistake of making a lumbar puncture and got perfectly clear normal fluid. The man grew worse and worse. I advised at the time that he should be brought to Chicago to a neurosurgeon, but he failed rapidly and died six days later. The right hemisphere was entirely covered by a quite thick subdural clot, so that this was a very fine simulation of a case of meningioma.

DR. WALTER FREEMAN, Washington, D. C. I have seen at least thirty of these subdural hematomas among some 1,500 cases coming to necropsy. They were practically all free from symptoms until shortly before the end, probably because the patients were already so tangled up in their mental processes that they didn't give clear indications of the trouble within. There is a certain tendency for these lesions to occur in older persons. I question the interpretation that Dr Gardner has given. I think it is not so much the fragility of the veins that is responsible for the rupture as it is the atrophy of the brain, carrying the cerebral cortex away and leaving a longer stretch of vein to be injured. Often no history of injury is found. Is it Dr Grant's impression, or just a slip of the tongue, that cerebrospinal fluid is found in these cysts? It is my impression that the fluid is much more like blood plasma mixed with autolyzed blood. These subdural hematomas do not progress slowly over a period of time but by leaps and bounds, quiet for a while, then starting up again as shown principally by the layer after layer deposited in the clot. In my experience the clots are fairly frequently bilateral. In a few cases in which the history of trauma was not very clear, encephalography revealed yellowish fluid. In two of these cases the sac was apparently ruptured, because after withdrawal of 50 or 60 cc. of fluid by the lumbar route there was a sudden gush of brownish fluid. These patients did badly. The cause of the stupor has a particular relationship to the type of lesion. I believe that I have shown one mechanism by which this might occur, namely, compression of the corpus callosum by herniation of the brain, beneath the falx. There is a marked tilting up of the corpus callosum with considerable pressure in that region. This is the only remarkable manifestation, I think, that occurs in the displacement of the hemispheres toward one side.

DR. J. W. WATTS, Philadelphia After removal of the hematoma in some of these cases the brain fails to expand, and I should like to ask Dr Grant whether he has an explanation for that, and also what he does in the cases in which

the brain fails to expand I believe that these patients usually do rather poorly

DR. C. C. NASH, Dallas, Texas I have had one case of chronic, mild headache that follows a mild injury and suddenly becomes very severe. The interpretation was that the hematoma sac had ruptured into the subdural space, spreading the blood. Another thing is the explanation of the so called latent interval. I can understand why it gradually increases. Why do these patients carry this large sac so long and suddenly become worse, as has been brought out? In my oldest case the operation was performed two years and four months following injury. It has been my experience that the spinal fluid pressure has been increased, in some cases quite high, up to 28 or 30 mm, and that high pressure is not an indication of choked disks, as I have had many indications of high pressure due to brain tumor without the presence of choked disks. The thing that has been very valuable to me in diagnosis is the use of ventriculography, particularly in cases of unconsciousness.

DR. MAX M. PEET, Ann Arbor, Mich. A few years ago Dr. Ernest Sachs of St. Louis presented a patient with a cerebellar subdural hematoma exactly simulating in appearance and apparently exactly the same in etiology as the type that has been described today. This man had struck a wall with his forehead and the curbing with his occiput and presented symptoms of a cerebellar tumor, but at operation a suboccipital hematoma was found. So far as I know it is the only one that has been mentioned.

DR. EDGAR A. KAHN, Ann Arbor, Mich. With regard to the difference between children and adults I think that this answers the question brought up by Dr. Watts. In children there will sometimes be seen a very tough membrane holding the brain down, and the brain does not expand until the membrane has been incised. I cannot imagine fluid passing from the subarachnoid space into the sac through this tough membrane. The fluid that gradually accumulates in the sac, increasing the intracranial pressure, comes as a dialysate through the thin walled vessels of the membrane adherent to the dura.

DR. FRANCIS C. GRANT, Philadelphia. Dr. Putnam questions the severity of the injury. All these reported cases have been chronic cases in which there has been a well encysted clot and no fresh blood. They would fall into the groups, probably V and VI, of the classification that McGrath recently made of chronic subdural hematoma. I quite agree with Dr. Putnam that subdural hemorrhage is unlikely to occur after severe injury, for there is an edema of the brain following severe injury that prevents severe bleeding. Furthermore, a contusion of the brain occurs rather than rupture of the small vessels on the cortex. In chronic subdural hemorrhage it is the rupture of the small vein running from the dura to the cortex that is the etiologic factor. Dr. Kahn has given an explanation for lack of expansion of the brain: that part of the cyst wall which adheres to the arachnoid may be firmly attached to the arachnoid at two widely separated points in a tight band across the brain. If one reaches in and ruptures this membrane, the brain will expand. I have never seen this condition, but it appeals to me as a possible explanation. I have no particular method for handling the situation when the brain doesn't expand. I would certainly drain. It has been suggested that the use of hypotonic solution by vein might cause expansion of the brain. Ringer's solution has been used in the spinal canal to push the brain up. With regard to Dr. Freeman's question I said cerebrospinal fluid and I meant cerebrospinal fluid. I think that the cyst fluid is broken down blood diluted with spinal fluid. It has a lot of protein and a lot of blood clots in it but I think that the reason for the steady slow expansion is the entrance of cerebrospinal fluid into the sac. Furthermore, I have never seen a clot that had layers. All the clots have been examined microscopically and they have been entirely cohesive and entirely uniform, and there hasn't been anything suggesting a second hemorrhage following on the first. As to the question about cephalograms these were made in one case. The patient had headaches for two years and a half, and curiously enough, the cephalogram was apparently negative. The man had a right and left subtemporal decompression. A rather large left-sided subdural hematoma was found which was evacuated.

THE BIRTH ORDER OF 582 MALFORMED INDIVIDUALS

DOUGLAS P. MURPHY, M.D.

AND

MILTON MAZER, M.D.

PHILADELPHIA

The cause of congenital malformations remains unexplained. It is not known whether they are due to defects in the germ plasma of the parents or to injury of the growing embryo. In order to throw light on the question, an investigation of a series of families, each possessing a defective child, has recently been made. Among the characteristics studied in these families was the birth order of each normal and of each malformed child. An analysis of the data on this point forms the basis for the present report.

Still¹ has studied the birth rank of malformed children seen by him in private practice. He concludes that congenital heart disease, congenital pyloric stenosis and various other defects appear more often in the first born than in the later born.

Macklin² has studied the place-in-family in a series of malformed individuals reported in the literature. Contrary to Still, she concludes that congenital heart disease and pyloric stenosis do not show a bias for the first birth rank. As a result of her analysis of the birth positions of a thousand malformed individuals who exhibited defects similar to the ones in our series she believes that defects are no more likely to appear in one birth rank than in another.

A number of studies have been made on the birth order of mongols. Physicians have long noted that mongols are most often born late in large families. Statistical studies on mongols, in which a reconstruction was used to correct for variations in the size of the family, have been made by Pearson,³ Penrose⁴ and Ordahl.⁵ These observers agree that mongols appear more often in later birth ranks than would be expected by chance. It is thus quite evident that as yet there is no agreement as to the place-in-family in which malformed individuals are most likely to occur.

MATERIALS AND METHODS

Collection of Data—There were found in the files of the Bureau of Vital Statistics, Department of Health of the State of Pennsylvania, 130,132 death certificates for still-born and live-born individuals who died in Philadelphia during the five years between Jan. 1, 1929, and Dec. 31, 1933. Each of these certificates was examined, and the data on those noting the existence of any congenital defect were transcribed to duplicate official forms, 1,476 such certificates were located.

From the Gynecean Hospital Institute of Gynecologic Research and Department of Obstetrics and Gynecology University of Pennsylvania School of Medicine

The authors are indebted to Dr. Emlin Jones, director of the Bureau of Vital Statistics, Department of Health of the State of Pennsylvania, to Miss Florence G. Hardy, chief statistician, and to Miss Mary A. Cleckner for their continued help on the project.

The investigation of which the present report forms the first contribution was aided by the John G. Clark Fund of the University of Pennsylvania, the Federal Works Administration and the Local Works Division through the cooperation of the State of Pennsylvania Department of Health.

* An example of the interpretation of this table follows. In the case of the 116 families (column 2) in which there had been three conceptions each 108 families possessed one defective child each six possessed two defective children and one possessed three defective children.

† One of the pregnancies resulted in malformed twins.

located. The group forms a consecutive series. The defective children all died within a given geographic area and a given period of time.

THE DATA

The birth rank of all siblings was determined for a total of 539 families (table 1). There were 2,057 conceptions, or an average of 4 per family.

All abortions and miscarriages were utilized in determining the ordinal number of subsequent pregnancies. When no mention was made of a defect in the embryo, it was classified as being normally developed. Of the 2,057 conceptions, 1,475 resulted in normal offspring.

The distribution of the malformed siblings by size of family and by number of defective siblings in each family is recorded in table 2. Five hundred and six

families contained one malformed sibling, twenty-three contained two and ten contained three.

The location of the chief malformation in the 582 defective individuals is shown in table 3. Of these, 77.5 per cent were external defects. Hydrocephalus and spina bifida constituted nearly one half of the total group.

There were only four patients with mongolism, which, as has been mentioned, shows a bias for the later birth ranks. These four are obviously too few to affect the attributes of the series.

The distribution of the observed malformed individuals, arranged according to birth rank, is shown in table 4, column 2, together with the theoretical distribution of the same individuals (column 3) if they had been distributed by birth rank according to the

14	1	0.1	
Totals	482	582.8	

* Malformed individuals distributed according to birth rank. Column 2 the observed rank of the 582 malformed individuals. Column 3 the theoretical rank of the same individuals computed on the assumption that they occurred at random by the use of the Greenwood-Yule reconstruction method. Column 4 the ratio of the observed (column 2) to the expected (column 3). If the malformations were distributed at random throughout the various ranks the expectancy factor (column 4) would be 1.0 for each birth rank. Note that in the first four ranks the malformed individuals occur less often than would be expected by chance and in the later ranks more often than would be expected by chance.

in a family of two siblings, there is one-half chance that each will be affected, in a family of three siblings, only one-third chance, and so on.

6 Greenwood, M. and Yule, G. U. On the Determination of Size of Family and of the Distribution of Characters in Order of Birth from Samples Taken Through Members of Sibships. *J. Roy. Stat. Soc.* 77: 179 (Jan.) 1914.

The fractions contributed to each birth rank by each family were then totaled by birth rank for the entire group of families. In families in which defects were observed in two siblings, each birth rank was allotted double the fractional value given to families with only one defective sibling. In families with three defective siblings, each birth rank was given triple the value of that allotted to families with only one defective child.

The relation between the distribution of the observed malformed individuals (table 4, column 2) and their expectancy if they had occurred at random (column 3) is expressed as a simple ratio in column 4 and graphically in the accompanying chart. These show that in the first four ranks the defective individuals occurred less often but in the later ranks more often than would be expected by chance. In the seventh rank the defects occurred twice as often and in the ninth rank three times as often as would be expected.

In order to determine whether these two distributions differed to a significant degree, they were compared by means of the method of Penrose.⁴ The distribution of the observed normal individuals (table 1, column 4) was determined by subtracting the observed

Graphic presentation of figures in table 4 column 4. The base line represents birth rank. The vertical line represents the expectancy factor which is derived by dividing the number of observed malformed individuals in each birth rank by the number of expected malformed individuals. This factor indicates the relative frequency with which observed malformed individuals occurred. If they had been distributed at random all the bars would have ended at the horizontal line marked normal expectancy. Note the increasing expectancy from the fifth rank onward. The malformations appeared in the seventh rank twice as often and in the ninth rank three times as often as would be expected by chance.

defective individuals (column 3) in each birth rank from the total of all individuals in that rank (column 2). The following values were then computed for the observed distributions (table 5)

TABLE 5—Observed Distribution

	Number	Mean Rank	Standard Deviation
Malformed (M)	1,82	3.02	
Normal (N)	1,475	3.35	
All (T)	2,037	3.20	± 2.32

The standard deviation of the difference between the mean ranks of the observed normal and the observed malformed individuals was calculated by the formula given by Penrose ($\sigma_{(T)} \sqrt{\frac{MN}{T}}$) and found to be ± 0.12 .

The distribution of the expected normal individuals by birth rank was then determined in the same way as for the observed normal individuals from the data in table 4 column 2, and table 1, column 2. The mean

birth ranks for both the observed and the expected distribution are given in table 6.

The mean rank of the expected malformed (2.46) is 1.13 ranks ahead of the expected normals (3.59). In other words, if it is assumed that the malformed are distributed at random by birth rank, one would expect that the mean birth rank of the malformed would, in our families, be 1.13 ranks ahead of the mean birth

TABLE 6—Observed and Expected Distributions

	Observed	Expected
Malformed	3.02	2.46
Normal	3.35	3.59
All	3.26	3.26

rank of the normal individuals. The observed malformed, however, are only 0.33 rank ahead of their normal siblings. Therefore, the observed malformed individuals occurred 0.80 rank later than would be expected, if they were distributed at random. Since the average displacement of the observed malformed in relation to their normals (0.80) is more than six times the standard deviation of the difference between the mean ranks of malformed and normals (± 0.12), this displacement is statistically significant. It may be concluded that the malformed individuals in this group are on the average later born than would be expected by chance.

COMMENT

It appears evident that congenital malformations of the types that constitute our data are, on the average, much more likely to occur in the later than in the earlier birth ranks. They took place less often than is predicted in the first four ranks but considerably more often in all other ranks. The relative probability of their occurrence rose rapidly from the fourth rank on, being twice the expected value in the seventh rank and three times this value in the ninth rank.

Our observations should not be interpreted as meaning that each of the types of malformation in the group necessarily shows a bias for the later birth ranks; they merely supply an average result. It is quite possible that some of the defects may show a preference for the first rank or may be distributed at random. These two possibilities, however, are likely only for those malformations which constitute a small part of our data, since the average is in the direction of the later ranks. While it seemed desirable in view of the work of Still¹ and of Macklin² to treat congenital heart disease and congenital pyloric stenosis as separate groups in order to determine their distribution by birth rank, the number of cases of each proved too small to justify such a procedure.

Though the frequency of congenital malformations appears to vary with birth rank, a causal relationship between the two cannot be assumed to exist. It may well be that the occurrence of malformations is actually influenced by some factor that is correlated with birth rank. Possible factors that have been suggested are paternal and maternal age. For example, Penrose⁴ has shown that the occurrence of mongols is related to maternal age and appears to be influenced by birth rank only because birth rank and maternal age show a fair correlation.

CONCLUSION

Congenital malformations of the types that constitute our data occur on the average less frequently in the earlier birth ranks and more frequently in the later birth ranks than would be expected by chance.

TOTAL CYSTECTOMY AND URETERAL TRANSPLANTATIONS IN MALIGNANT CONDITIONS OF THE BLADDER

WITH A DESCRIPTION OF A NEW OPERATIVE PROCEDURE

REED M. NESBIT, M.D.
ANN ARBOR, MICH.

The surgeon who is in constant contact with cases of bladder neoplasm is singularly struck by the paradox of curability of this disease. Whereas simple fulguration or irradiation provides absolute cure in many malignant conditions of varying size and location, one frequently sees one's best directed efforts go for naught in situations which at their onset seem the most hopeful. The Cancer Registry¹ is providing valuable data regarding progress in dealing with this problem, but a scrutiny of the reports offers a shocking reminder that in too vast a proportion of cases the generally accepted criteria of treatment are inadequate. Compared to other visceral neoplasms bladder carcinomas do not tend to become metastatic at an early date and should perhaps therefore be more often cured than is obviously the case. One might reasonably raise the question as to whether early radical surgery in the form of cystectomy might not prove advantageous in the long run. Success in the treatment of malignant conditions of the rectum has progressively followed an increase in radicalism and perfection of technic in that field during the past two decades.

Edwin Beer² and Quinby³ have pointed out that removal of the bladder with a malignant tumor is not a very formidable procedure. Were it not for the difficulties involved with the disposal of urine, it is safe

to say that cystectomy would long since have been the accepted treatment of the majority of malignant growths of the bladder.

The accepted indications for cystectomy are

1 Cases presenting involvement of the trigon⁴ so that the ureteral orifices cannot be spared when destructive methods of treatment are used

2 Those presenting infiltrative involvement of the vesical outlet,² so that adequate attack locally is destructive to the sphincters

3 Multiple infiltrative tumors

4 Neoplasms of low malignancy which show a marked tendency to recur and spread all over the bladder in spite of all conservative treatment and eventually become penetrative or highly malignant⁴

Several techniques have been described for removal of the bladder. The Coffey⁵ procedure consists of dissection downward from the fundus of the bladder to its base. Next the membranous urethra is severed between clamps, and the base of the bladder along with the prostate and seminal vesicles (in the male) is separated from the rectum by blunt dissection, completing the operation. George Gilbert Smith⁴ begins with a perineal incision, severing the urethra and dissecting the base of the bladder from surrounding structures and cutting the vasa. He then completes the operation from a suprapubic approach. One distinct advantage of this procedure is dependent drainage of the pelvis through the perineal wound. The technic recently described by Hinman⁶

appears to have distinct advantages over any heretofore offered. The method is a retrograde suprapubic dissection beginning at the urethra and is facilitated by a balloon catheter, which is retained in the bladder during operation, providing a means of traction and reducing trauma to the lesion. In performing cystectomy in the female it is advantageous to drain the vesical space dependently through a stab wound in the anterior vaginal wall.

There are three available methods of urinary disposal

Drainage of the kidney by nephrostomy or pyelostomy presents objections that contraindicate its use if other methods can be utilized

Cutaneous ureterostomy has long been in favor among European surgeons, while in this country Edwin Beer⁷ and Hugh Cabot⁸ have both stated the belief that this method is safer and therefore better than uretero-intestinal anastomosis. The drainage tubes and other apparatus necessary following the latter procedure are difficult to manage and can rarely be fitted sufficiently well to prevent some leakage of urine. Wade⁹ reported that in six cases in which he had performed cystectomy with cutaneous ureterostomy his collecting apparatus was never entirely successful in preventing leakage and therefore never satisfactory.

The ideal method from the standpoint of functional results is uretero-enterostomy. In most common use today are the three technics described by Coffey⁹ or modifications of them.

Technic 1 is probably the safest of the three, but since the transplantation is carried out in two stages, cystectomy requiring a third operation, the prolonged hospitalization period is a distinct disadvantage. This method has been utilized successfully in two cases at the University Hospital, but the objection mentioned led to the procedure being dropped.

Technic 2, in which bilateral simultaneous transplantation with ureteral catheters is done, was used in nine cases. Three of these patients died before leaving the hospital, one as an immediate result of operative shock, one of pneumonia on the sixth postoperative day, and the third on the thirtieth postoperative day of a massive collapse of the lung. The anastomoses were functioning perfectly and the patient had been afebrile for twenty-one days. The other six cases of this group did exceedingly well.

One patient was treated by a modification of the Coffey transfixion technic as recently described by Higgins¹⁰. This patient died on the fourteenth day following the first stage. Autopsy revealed the cause of death as peritonitis, probably due to a leak at the trans-fixed area.

This high mortality rate has led to search for a method offering less hazard to patients. A two-stage method was developed, which proved so satisfactory in laboratory animals that it was employed recently on two patients having malignant conditions of the bladder.

At the first stage both ureters are mobilized for a distance of 4 inches (10 cm) at about the level of the pelvic brim and are embedded between the muscularis and the mucosa of the upper part of the rectum without opening the lumen of the intestine or interrupting the continuity of the ureter, as shown in the accompanying illustration. Healing of this implantation area takes place by primary union. The second stage is done from fourteen to twenty-one days following the first. The ureters are severed an inch distal to the area of implantation. A purse-string suture is now laid in the intestinal wall about the base of the severed ureter. A small incision extending into the lumen of the intestine is made as closely as possible to the base of the stump of ureter. The end of the ureter is introduced into the lumen of the bowel and the purse string drawn,

completing the anastomosis. A procedure utilizing this principle was described by Winsbury-White in 1933.¹¹

Advantages of this method have been demonstrated experimentally. There is no interruption of urinary flow at any time. Primary union of the first-stage implantation area prevents the constriction in that area, which is so commonly seen following direct implantation operations. Ascending infections in the ureteral wall have been strikingly absent in experimental animals.

The patients operated on at the University Hospital have not been observed over sufficiently long periods to evaluate the end results. Thus far they have done exceedingly well and offer encouragement for the use of the method employed.

SUMMARY

1 Removal of the bladder with a malignant growth is not a very formidable procedure.

2 The greatest obstacle to radical surgery for the cure of cancer of the bladder is a lack of safe and satisfactory methods of urinary disposal.

3 Cutaneous ureterostomy is probably the safest method available at this time.

4 Uretero-intestinal anastomosis provides the best functional results.

ABSTRACT OF DISCUSSION

DR EDWIN BEER, New York. In doing a total cystectomy, one should remove the organ working against the lymphatic stream. This is a fundamental surgical principle, and the perineal approach or the recent suggestion of Hinman violates this principle, as they are bound to squeeze carcinoma cells into the lymphatic stream. The method of disposing of the ureter in the rectum or sigmoid prior to total cystectomy is essentially a modification of the Higgins technic but theoretically has the disadvantage that, at the second operation when the cystectomy is performed the intestine is opened at two points, with the dangers incidental to such a procedure. I believe, moreover, that it is objectionable to divide into two steps the operation for carcinoma of the neck of the bladder, carcinoma involving both ureters or diffusely infiltrating carcinoma. The final decision in any case must be made at the operating table by palpation and at times by visualization of the growth. If one transplants the ureters prior to this decision, one's bridges are burned and one is committed to a secondary total cystectomy. The mortality in this procedure seems to be more than 30 per cent, according to a recent statement published by Hinman in reviewing some 800 published case reports. When one adds to this the mortality of the essential part of the whole procedure of total cystectomy, the combined mortality rises considerably and may be too high to make this procedure in any sense popular. I have usually transplanted the ureters into the skin at the same time that I have removed the bladder, and it is a mistake frequently made to consider these patients with intubated ureters miserable, uncomfortable and ostracized from society, as most of them lead a fairly or absolutely normal existence, relieved of distressing pain which an incomplete resection might lead to. If the patients treated as just mentioned are uncomfortable and miserable, they can have a ureterocolostomy performed in the lumbar region, with comparatively little danger that the peritoneal cavity will be infected. I believe that total cystectomy for certain cases of carcinoma of the bladder is justifiable. The mortality is not prohibitive, carried out as I have suggested, and, successfully carried out, prolongs life and cures the malady, in fact, in my series of cases prior to 1930 I found that four out of seven patients lived for five years.

DR JEROME LYNCH, New York. The dual interest in this subject for both the urologist and the proctologist is clear. The trigon of the bladder is closely associated with the internal sphincter, and this can be proved by an injection of epinephrine,

which causes a contraction of the trigon and also of the internal sphincter and accounts for many of the reflex symptoms, such as trigonitis, whereas if acetylcholine is injected contraction of the fundus of the bladder and the rectum and colon occurs. I was wondering, hearing about Dr. Lowsley's operation, whether perhaps acetylcholine wouldn't be just as good. I was struck today by the multiplicity of suggestions for the cure of these tumors of the bladder, and, while I think that it is all very well in this society of specialists to discuss it, it is unfortunate when men who are hanging on our words as to what they should do are told that there are so many methods of treating these tumors. I think it would be better to come to some conclusion beforehand as to what procedures are believed to be best and to grade them 1, 2, 3.

DR. C. C. HIGGINS, Cleveland. I believe that cystectomy and transplantation of the ureters into the rectosigmoid will be employed much more frequently in the next few years than they have been in the past. However, I feel strongly that a critical evaluation of the methods of treatment should be considered before this radical procedure is advised. If a small tumor of the bladder can be treated adequately by radium, segmental resection or the type of treatment discussed by Dr. Beer, I do not believe that there is justification for advising cystectomy. The excellent results which Dr. Pfahler has secured by roentgen therapy in cases of carcinoma of the bladder are most gratifying, and I am at a loss now to tell what type of tumor should be treated by the radical operation. In the cases that he has presented, the cystograms show extensive involvement of the bladder and they represent the type of case for which I have advised cystectomy and transplantation of the ureters in the last two and a half years. I have not secured such striking results after the use of roentgen therapy. In the past, some fundamental observations, which have proved the advisability of transplantation of the ureters into the rectosigmoid, have been the impossibility of performing a bilateral, simultaneous transplantation of the ureters without interruption of the function of the kidney and infection, which has been the most common cause of death regardless of the technic employed. Coffey's modification of Martin's technic did not permit bilateral transplantation without some danger of the interruption of renal function. By the technic that I presented in 1933, an operation can now be performed by which the two ureters can be transplanted simultaneously without any danger of obstruction if the submucous principle is used. There is practically no danger from peritonitis and the valvular mechanism is maintained. Recently Dr. Nesbit has further modified my operative procedure in a technic similar to that which has been presented by Dr. White. I believe that too much time is being devoted to the perfection of various technics for the operative procedure and that sufficient attention has not been given to investigations of the cause of hydro-ureter, hydronephrosis and renal sepsis, which have followed transplantation of the ureter. The theory of Dr. Coffey that the intrarectal pressure is responsible for the dilatation of the ureter has not been substantiated or verified by my work in the experimental laboratory.

DR. HARRY O. LEPSKY, Cincinnati. With my associate Dr. Henry Freiberg I shall report at the American Urological Association in San Francisco a new technic for total urethrocystectomy in the female for carcinoma of the bladder. The operation removes the entire urethra and bladder by a combined vaginal and suprapubic operation. In contradistinction to the average opinion that the operation of total cystectomy is a formidable one, we wish to present evidence to the contrary, because our operations have been attended with a minimum of surgical shock and absolutely no hemorrhage. Our operation also conforms to the postulates as just set forth by Dr. Beer in that the removal of the bladder should not milk out carcinomatous tissue or little nests of cells either through the lymphatics or through the blood vessels, and we obviate this by taking care of the blood supply immediately before any attempt is made to remove the bladder itself. The lateral ligaments of the bladder are doubly ligated and severed and the bladder is removed by a retrograde dissection which has been started previously in the vagina. A second feature that we have introduced in our operation is that we remove an empty bladder. The advantages of removing the empty bladder

are that we have a smaller mass to contend with in the pelvis, that the lateral ligaments are more easily accessible and that the blood supply is much more easily taken care of. The operation to which I refer is surgically correct in that we do not open the bladder at any time during the operation, and, as has been mentioned by Dr. Nesbit and others, the problem of drainage after cystectomy is certainly a very important one.

DR. WILLIAM C. QUINBY, Boston. I am in agreement with treating tumors of the bladder that are susceptible of being so treated by less radical methods, but there is no question what ever in my mind that total cystectomy is an operation that should be carried out in instances of more malignant tumors (grades 3 and 4) when they are situated at the lower segment of the bladder and when, being so situated, their resection would definitely interfere with subsequent normal function of the bladder. The method of disposition of the urine after cystectomy is a correlated subject. Transplantation of the ureters into the skin, as Dr. Beer assures us, is a comfortable procedure for some persons, but in other patients it may create a very disagreeable condition. Though a wise procedure in some instances, it is most certainly not an ideal disposition of the ureter. The methods of transplanting the ureters into the intestine vary according to whether the two must be transplanted at once or only one at a time. In the majority of experimental observations on ureteral transplantation it seems to have been forgotten that such a plastic operation depends for its success in large measure on its simplicity and absence of trauma, together with conservation of blood supply and avoidance of infection. In my opinion all so-called prosthetic aids, as buttons, catheters and electric cutting wires, only complicate and jeopardize the success of the procedure. The method of anastomosis advocated by Dr. Nesbit fulfils these postulates and so deserves commendation.

EXPERIMENTAL PERIPHERAL GANGRENE

EDWARD J. McGRATH, MD
CINCINNATI

The intense interest which in recent years has centered about the problems presented by peripheral vascular disease has thrown into painfully clear relief the meager limits to present knowledge of the nature of these maladies. Particularly is this true of the more obscure presenile peripheral arterial disturbances. Clinician and experimentalist alike appreciate the blindness of the fight being waged with thrombo-angitis obliterans. Clinically, physicians seem to be merely marking time, while experimentally they are little nearer the solution of the etiology of the disease than they were when the disease was first described in detail by Buerger.

This is quite intelligible when one considers the fact that there is as yet no clear knowledge either of the character of the initial lesion in the disease or of its chronological development. Patients present themselves in what is essentially the end stage of the process, and the physician's concept of what has gone before is a purely hypothetical reconstruction, on which there is no unanimity of opinion. Two major schools of thought exist. The one holds that the disease begins as an acute panarteritis, associated with thrombosis, the process gradually becoming chronic and being characterized by periods of acute exacerbation relieved by stages of quiescence. The second group believes that thrombo-angitis obliterans is a chronic process from the outset,

beginning as a chronic inflammatory reaction in the adventitia of the vessels associated with intimal proliferation and secondary thrombosis, that all coats of the vessel wall are progressively involved, but that the disease always remains an essentially chronic disturbance. More recently, Popoff has suggested that a congenital anatomic abnormality may be the basis for the disease.

With such heterogeneity of opinion, experimental duplication of the initial lesion of thrombo-angitis obliterans presents a practically insuperable difficulty. Laboratory workers have been satisfied to accept as adequate criteria on which to base their studies the phenomena of intimal proliferation and thrombosis, together with gross trophic changes in the area distal to and supplied by the occluded vessels. Even with these relatively simple criteria, however, previous experimental attempts, directed for the most part toward the establishment of a specific bacterial etiologic agent, have been, to say the least, disappointing. It occurred to me that possibly the direct character of previous approaches to the problem was defeating its own end. Examining the clinical nature of the disease, I felt that there could be found some salient characteristic which might offer a new experimental approach, less direct but more promising of results.

It was first necessary, however, to produce a lesion which would reasonably approximate that postulated as the early pathologic change in thrombo-angitis obliterans. Furthermore, in order to analyze mathematically whatever results might accrue from an experimental manipulation of such a lesion, it was necessary that the desired change be constant in its occurrence. The answer to this phase of the problem was suggested by the work of Kaunitz, who for several years has been studying the vascular phenomena associated with ergot gangrene in fowl. For various reasons the chicken was not satisfactory for my purposes. I therefore utilized the method of Rothlin and Polak, namely, the production of gangrene in the tail of the albino rat by the use of toxic quantities of ergotamine tartrate.

White rats, male and female, weighing between 140 and 170 Gm, were used. To them, in successive series, ergotamine tartrate (gynergen-Sandoz) was administered in doses varying from 25 to 100 mg per kilogram of body weight. The results coincided with the initial experiences reported by Rothlin and Polak. In both male and female rats there was a uniform, regular production of gangrene of the end of the tail in from ten to twenty-eight days. The gross phenomena consisted in the successive color changes of pallor, cyanosis, dry gangrene, and demarcation of the gangrenous portion, followed by anesthesia. The time of onset of these changes varied with the amount of ergotamine tartrate employed. When gangrene was definite the tails were amputated and sections for microscopic study were taken at various levels. (It should be noted at this point, lest there be any misconception as to possible dangers arising from the exhibition of ergotamine tartrate in therapeutic amounts, that, translated into clinical terms, the quantities of the drug employed in these experiments represent an enormous amount of the substance, e.g., from 1,250 to 5,000 mg for an average 110 pound [50 Kg] woman, whereas the therapeutic dose varies from 0.25 to 1 mg.)

Microscopically, the most pronounced change was the marked cellular proliferation and swelling of the intima of the small arteries, where in some sections the lumens were

almost completely occluded. To a lesser extent this process involved the veins and the large ventral artery of the tail. In the latter vessel the characteristic finding was the presence of a thrombus to which the intima was adherent. In some sections the intima seemed to have been drawn completely away from the internal elastic membrane, while at other points there was a definite attachment to the wall of the vessel. In sections taken from tails in which demarcation had occurred, the thrombus had been organized and canalized, the penetrating channels demonstrating in high magnification a definite endothelial lining. Leukocytic reaction, either in the coats of the arteries or arterioles or in the periaarterial tissues, was not appreciable.

In the veins, contrariwise, in addition to the previously mentioned changes, were found areas of marked thrombophlebitis, especially in those veins superficially placed. Here the perivenous tissues were all involved in an intense polymorphonuclear leukocytic infiltration. The only noticeable alteration in the nerves was that in high magnification there appeared to be a vacuolization of the myelin sheaths.

Thus I had found an agent that satisfied the two basic requirements essential to the experiments I had in mind. First, the lesion produced by ergotamine tartrate in toxic doses fulfilled the criteria usually accepted by workers in the field of thrombo-angitis obliterans, second, these changes were produced regularly, so that any experimental manipulation could be quantitated mathematically and the stability of the result studied by standard biometric tests.

Returning to the original objective, namely, an indirect approach to thrombo-angitis obliterans by way of some salient clinical constant of the disease, I was impressed, as all other students of the malady have been, by the fact that with the exception of hemophilia there is no other disease so markedly sex limited as thrombo-angitis obliterans. Many explanations have been offered to account for this. I chose to investigate the most obvious of these, i.e., the difference in the sex hormone.

Four series of animals were employed, series 1, 2 and 3 being composed of males and females from 140 to 170 Gm in weight, and the dosages of ergotamine tartrate being 25, 40 and 60 mg per kilogram of body weight in the respective series. The rats were divided into three groups (a) normal controls, (b) control groups in which ergotamine alone was used and (c) experimental groups to which an initial dose of ergotamine tartrate was administered, followed after an interval of twenty-four hours by daily injections of theelin in aqueous solution. The amount of theelin employed was 2, 3 and 3 rat units in the respective series. These theelin administrations were continued over a period of thirty days, and the rats were observed for an additional twenty days. The results were invariably the same. In the males there were no changes in the normal controls, and a comparable amount of gangrene appeared in the rats receiving theelin. Again the picture in the female group was quite different. The normal controls showed no change, and gangrene developed in all the ergotaminized controls. In the experimental groups, however, in which theelin had been administered daily there was no gangrene whatever, nor could microscopic evidence of vascular disease be found. Finally, the fourth series, composed entirely of females, was given the maximum amount of ergotamine

tartrate that I cared to use, that is, 100 mg per kilogram of body weight. The theelin dosage was 5 rat units daily. In this series, all but four of the experimental animals behaved as in the preceding series. In four of the rats, however, cyanosis quickly developed at the end of the tail. The theelin dosage was promptly doubled. In two of the four gangrene developed despite all efforts to allay the process. It is to be noted, however, that in these two rats the amount of tail involved in the gangrenous change was less than half that occurring in the unprotected animals. The other two animals recovered from the impending local disaster and at the end of the experiment could in no way be differentiated from the other theelinized rats. Application of the chi square test for probability to these results indicates that the probability of such a phenomenon accruing from the operation of chance alone is less than 1 in 400 billion.

The effect on the peripheral vascular system of estrogenic substances, such as theelin, is as yet too little known to offer any satisfactory explanation for the phenomena that I have observed. In point of fact, the alterations, physiologic and anatomic, in the peripheral vascular bed following the use of ergot or of its specific alkaloids in toxic quantities have given rise to a most confusing difference of opinion, which space does not permit me to discuss. I shall content myself at present with simply recording the results of the experiments.

RECAPITULATION

I do not claim to have reproduced thrombo-angitis obliterans, nor do I offer these experiments in support of the theory that the basic lesion in thrombo-angitis obliterans is attributable to ergot intoxication. I have merely utilized ergotamine tartrate as an agent to produce a lesion comparable to what is usually postulated as the initial lesion in thrombo-angitis obliterans. Nor do I offer the theory that there exists a necessary connection between the sex limitation of thrombo-angitis obliterans and the phenomena observed that female rats, protected with sufficient doses of theelin, failed to develop the gangrene which in my hands invariably resulted from the administration of toxic quantities of ergotamine tartrate. I do feel, however, that this curious phenomenon suggests the possibility that the failure of thrombo-angitis obliterans to manifest itself in the female may be associated with a protective action of the estrogenic substance in the internal secretion of the ovary. Finally, I believe that this experience offers a new, or at least rehabilitates an old, approach to the problem of the etiology of thrombo-angitis obliterans.

Cincinnati General Hospital

ABSTRACT OF DISCUSSION

DR. D. W. G. MURRAY, Toronto. I find it difficult to add much to this interesting paper. I believe that it has opened a method of investigation which may prove useful in developing some method of dealing with this important group of vascular diseases. It is well known that ergotamine in physiologic therapeutic doses has a reversal effect on blood vessels. That is, in an area of the vascular tree which is under the effect of epinephrine the vessels that are in spasm and that are placed under the influence of ergotamine will undergo extreme dilatation. It is known that the coronary vessels of the heart, instead of being constricted by epinephrine, are dilated. I should like to ask Dr. McGrath whether ergotamine reverses this effect or if a similar effect might be expected on the coronaries, which would be a very helpful approach to the investigation of coronary disease. The length of time between the administra-

tion of ergotamine and the development of the lesion was interesting. I should also like to ask whether it is known what part of the ergotamine produces the intimal changes. This interval of eight to ten days during which time theelin is administered may provide the opportunity for the neutralization of the ergotamine by the theelin. Does the ketone group or the hydroxyl group change this ergotamine so that it does not have its important pathologic effect on vessels?

DR. E. J. McGRATH, Cincinnati. As to the effect of ergotamine on coronary vessels, I am unable to say. There has been a theory since 1927, advanced by Regniers, that the production of gangrene in the extremities, accidentally, in therapeutic doses is dependent on the blood index of epinephrine. I believe Dr. Murray had this in mind in mentioning the fact that there seems to be a reversal action in the presence of epinephrine by ergotamine. As to what fraction of the drug has its effect in producing this organic pathologic change, the Sandoz Chemical Works is unable to inform me. It is true that it has recently developed a fractionation of ergotamine with a molecule much smaller than the present one. As Dr. Rothlin himself has been unable to inform me as to which of these is the active factor, I am again unable to answer Dr. Murray's question. Concerning these particular experiments, I would again emphasize the fact that they represent merely a preliminary study. In and of themselves they probably have no definite significance, but, as I tried to indicate at the beginning of this discussion, they point a way to a new approach to what has been heretofore a most difficult problem. In view of the attitude of some workers, particularly the recent researches of Dr. Popoff, that this disease represents a congenital anomaly rather than some superimposed dyscrasia, I feel that, if anything, my observations offer a more hopeful approach to the disease than by considering it something with which a person is born and therefore with which he will ultimately die.

RODENT PLAGUE IN CALIFORNIA

W. H. KELLOGG, M.D.

Chief, Division of Laboratories, California State Department
of Public Health
BERKELEY, CALIF.

Not long after the present pandemic of plague reached the shores of America in 1900, where it was recognized in the Chinese colony of San Francisco, it was found to be present among the ground squirrels in Contra Costa County. At that time the close association of rodent and human plague was not so clear as it is at present. In 1900, when my plague experience began, the work of the English and the German plague commissions in India was only fairly begun and the idea of flea transmission was new and not generally known.

In the early days of any revolutionary discovery there is a period when those who accept it have their thinking partially clouded by the holdover of ideas from the past, and we who took part in the early history of plague in America¹ were in that transitional stage. We knew that the rat was important, but we did not proceed as if we did. The trouble probably was that the full significance of the combination of rat and flea had not become thoroughly established. I remember of Dr. Kinyoun, than whom there was no better bacteriologist probably in the country, relating the occurrence of an outbreak of plague in Hawaii in the Chinese colony immediately following the opening of some shipments of sweets from China for the New Year's celebration. There was in our minds some mysterious connection with this shipment, notwithstanding our knowledge of the fragility of the plague bacillus and its lack of resistance to drying.

Read before the Western Branch of the American Public Health Association, Helena, Mont., July 3, 1935.
¹ Kellogg, W. H. Present Status of Plague with Historical Review. *Am. J. Pub. Health* 10:835 (Nov.) 1920.

By the time the second epidemic occurred in San Francisco, the epidemiology of plague was becoming more crystallized and Dr Blue, the federal officer in charge, ordered an examination of ground squirrels when two cases of human plague occurred in rural districts of Contra Costa County. Infected squirrels were found in 1908, and plague has been enzootic among the squirrels of California ever since. At that time an acute and very severe epizootic ensued, the number of plague infected squirrels picked up in that county being over 1,700 during the few years following 1908. This epizootic extended in the neighboring counties of the Bay area and it was accompanied by a human epidemic in San Francisco and Oakland, the number of cases between May 1907 and June 30, 1908, when the last case of this second epidemic of human plague occurred, being 160 and the number of deaths seventy-seven. A rat epizootic in the same cities was in progress at the same time, as is usual, the human outbreak being secondary to that among the rats.

Eradicative efforts were carried on by both the state board of health and the United States Public Health Service and at one time it appeared that these efforts might be successful and that the chapter would be shortly finished. In 1914 an authority in public health who was experienced in plague published an article on plague in California in which he ventured the prediction that plague was gone. The occasion for his optimism was the apparently complete suppression of plague as the result of the work of squirrel eradication that had been carried on jointly by the Public Health Service and the state health department. This campaign included a survey for the presence of plague infection beginning in 1908 covering most of California and parts of adjacent states and lasting until 1912, up to which time nine counties in California had been proved plague infected. Eradicative measures were concentrated on the nine counties and during 1914 plague was found only in four, the number of foci being seven, the number of ranches involved twenty-one, and the number of infected squirrels found sixty-nine. At the time of writing, all these ranches had been thoroughly poisoned and hunted over from three to five times with the result that on only one ranch was a plague squirrel found after the work was recorded as completed. With this cheerful picture in mind and with complete neglect of the history of plague, this author said "In view of the facts just set forth it is believed that the statement can safely be made that all discoverable plague has been eradicated from the state of California and that danger of its further spread has been removed."²

Now, what are the facts today, twenty years after the supposed complete extermination of the disease? Instead of nine known counties involved the number is nineteen, and last summer three new counties were added, in all three of which a virulent epizootic was in progress.

THE PRESENT EPIZOOTIC

March 16, 1934, on receipt of a communication from the state department of agriculture to the effect that some unknown disease was killing off the ground squirrels in certain sections of Kern and Tulare counties the bureau of sanitation of the state department of public health, under Mr Ross, launched an investigation. The plague survey crew operating with a motor truck was dispatched to the area and soon specimens

were coming in to the laboratory. Forty-one squirrels were shot and five found dead on the first day the crew started work and during the next three days 306 squirrels were shot and sixteen found dead on various ranches within a few miles of the town of Delano. These animals shipped to the laboratory were soon proved by animal inoculation and cultures to be heavily infected.

After the prosecution of work in this vicinity by our own men with the cooperation of the state department of agriculture, the latter being in charge of the exterminative measures, the chief of the bureau of sanitary inspections reported on July 21 that 5,973 squirrels had been shot and 2,853 found dead in the Kern-Tulare region, and of those sent to the laboratory 118 were reported positive. The number of plague foci located was forty-one, the area covered by the survey was about 2,421 square miles, and the extent of plague infected territory within this surveyed area was approximately 896 square miles.

While engaged in this work, about the first of June, Mr Ross received word from a representative of the United States Biological Survey that squirrels were dying in the vicinity of Alturas, Modoc County. An inspector was sent to that place at once and his first investigation resulted in the finding of twenty-eight dead squirrels and five dead wood rats on one ranch. Four of the squirrels and one wood rat were shipped to the laboratory, which soon confirmed the diagnosis of plague. This region, it should be noted, is fully 400 miles away from the Kern and Tulare focus and on the eastern slope of the Sierras.

The method of conducting the field work may be of interest. The truck is equipped with all the paraphernalia required for shooting and for postmortem dissection of the rodents. When they are brought in from the field by the hunters they are dumped into a large container in which there is compound solution of cresol, and for the transportation from the field to the headquarters at the truck milk cans with tight covers are used in which some chloroform is placed to destroy fleas in the interests of the safety of the men. From the solution the operator takes the squirrels one at a time, mounting them on a specially constructed metal tray provided with adjustable clips that hold the animal extended and with a sharp scalpel the skin is laid back completely, the lymphatic regions are inspected, the body cavities are opened and, when a suggestion of plague exists, organs are taken and placed in 6 ounce, wide mouthed, glass stoppered bottles, each bottle provided with a slip giving a description of the gross pathologic changes of the animals represented and giving the location from which they were secured, and they are then packed with ice in copper shipping cases and forwarded to the laboratory. The men in this squad have become truly expert in the skill and rapidity with which they can dissect the animals and the certainty with which they recognize the gross appearance of a plague infected animal.

On arrival at the laboratory the organs are spread out in petri dishes and examined by a bacteriologist experienced in rodent plague, as to both the macroscopic appearance and knowledge of its bacteriology. Smears are made and, when necessary, guinea-pigs inoculated. If the squirrels are from a district already proved and the appearance of the organs and the microscopic examination of the smears are definite, a positive report is

² Long. Pub Health Rep 29 3106

made forthwith. If, however, the locality is new or smears are negative in the face of suggestive pathologic changes, animals are inoculated.

THE NATURE OF PLAGUE

Plague is primarily a disease of rodents and characteristically it lies dormant in certain continuous foci of the disease, whence at intervals of decades or centuries it sallies forth in the form of human pandemics, which are not only world wide but may be century long. In these endemic foci the infection resides in some wild rodent of hibernating habit. Historical foci are those of Arabia and Mesopotamia, whence the black death of the Middle Ages emerged, and in Tibet and in Uganda in Africa. In Yunnan, in the interior of China, is the focus from which is supposed to have originated the present pandemic, which began with the appearance of plague in epidemic form in Hongkong in 1894. Calcutta was the next port of call, since which time most of the world has been visited, and plague is still active in a dozen or more countries.

The rat is the particular rodent usually thought of as the source of human plague. It is true that rats are, with an exception to be noted later, the immediate origin of human outbreaks, but they are not the remote source. The rat is the disseminator of plague by reason of his traveling propensities, and the beginning of a human pandemic nearly always is the infection of rats at some point of contact with rodents of a wild species in an endemic area. Human epidemics of bubonic plague result when plague has been introduced into the rat population, the infection spreading from rat to man and from rat to rat through the medium of the flea. The mechanics of the transfer is as follows. Fleas feeding on a rat with septicemic plague take up the bacilli with the blood. The plague bacilli do not infect the flea, but they multiply in the proventriculus, resulting in obstruction so that, on repeated efforts at feeding, blood is regurgitated onto the skin. Infection then takes place by entry of the organism through the bite puncture or other abrasion.

Plague in man assumes two clinical forms, the bubonic and the pneumonic. The former, characterized by involvement of the lymphatic glands forming buboes, is the commonest form and the one that principally prevailed during the epidemics of the Middle Ages called the black death. The pneumonic form, in which there is a pneumonia but usually no involvement of the lymphatic glands, is highly infectious from man to man direct without the mediation of rat or flea, because, the bacilli being in the sputum, transfer takes place by droplet infection. The case fatality rate of pneumonic plague is very high, almost 100 per cent, and the duration of the illness very short, from a few hours to two or three days. Since the same bacillus is concerned in the two types of infection, the reason for the occurrence of pneumonic epidemics is not clear, but there is some ground for believing that causes are both extrinsic and intrinsic. All pneumonias are favored by cold, damp weather and it is to be noted that the largest outbreaks of pneumonic plague, at least in modern times, have been in cold seasons. In India, where the climate is warm, only 2 to 5 per cent of the cases have been pneumonic except in Kashmir at an elevation of 5,000 feet, where an epidemic of 1,400 deaths occurred in very cold weather. Likewise the big pneumonic epidemics in Manchuria in 1911 occurred in winter weather. But there are manifestly other influences and these are of particular interest in relation to the present

epizootic in the new foci uncovered in the lower San Joaquin Valley and in the mountainous Modoc County district. I refer to the theory that a specific lung virulence is developed by the plague bacillus on passage through rodents of squirrel and ground hog type. This is suggested by the fact that in our experience pneumonias among rats are uncommon, but among squirrels they are very common and the character persists in guinea-pigs inoculated from these animals. Guinea pigs inoculated subcutaneously from rats and human beings during the 1907 bubonic epidemic in San Francisco, according to my recollection, never showed lung involvement, whereas in Los Angeles during and following a human pneumonic outbreak, when squirrels also were found infected the guinea-pigs frequently showed a pneumonia. Further testimony is seen in the Oakland pneumonic plague epidemic, which was started by a man who contracted an axillary bubo by contact with a squirrel and then developed a secondary pneumonia. The disastrous epidemic of pneumonic plague in Manchuria in 1910 and 1911 was not rat borne. It had its origin in trappers of tarbagans in the mountains. The tarbagan is the wild rodent that harbors plague endemically in that country.

ASPECTS OF THE PRESENT EPIZOOTIC

There are two particularly disturbing aspects of the present ground squirrel epizootic. One of these is the demonstration that the ground squirrel infection not only is not decreasing after thirty years but is, on the contrary, increasing and expanding over a much wider territory. Not only in the Coast Range and the interior valleys but now in the Sierras it is found. The establishment of a permanent endemic rodent focus is thus thoroughly demonstrated. In Asia such foci are apparently permanent. Perhaps in this country with our supposedly enlightened outlook on public health we may be able to root it out. The history of progress so far is not encouraging, however, and the more extensive the infected territory grows the more difficult and expensive will be the job.

The second important consideration relative to the appearance of plague in Kern, Tulare and Modoc counties is the evidence of renewed virulence and of increasing pulmonary tendency on the part of the prevailing strain of organism. The gross appearance of plague in ground squirrels is somewhat different from that in rats. In the latter animal there are five signs that may be encountered, rarely all at one time, frequently two, sometimes only one. These signs are subcutaneous injection, buboes, granular liver, large, dark spleen, and pleural effusion. In ground squirrels the subcutaneous injection that is of so much importance in rats is less noticeable. The liver, as in the rat, may show enlargement and a granular appearance. The spleen frequently resembles that organ in an inoculated guinea-pig, being greatly enlarged and studded with yellowish specks of focal necrosis, thus differing notably from the rat, in which animal the spleen rarely shows any specks but is smooth, dark and glistening and has a tense swollen appearance. Buboes, usually solitary, are common in squirrels, and the appearance of the bubo more often than in rats resembles the acutely necrotic and hemorrhagic bubo seen in man and in guinea-pigs. The most characteristic difference of all between rats and squirrels is the finding of nodules and hemorrhages in the lungs of squirrels but not in rats. The squirrels received from Kern and Tulare counties

have been remarkable in the number that have shown acute pulmonary plague, the appearance of the lungs being that of a lobular pneumonia with considerable edema exactly as in the human disease. Furthermore, the virulence of the strain is manifested by cases which are so rapid in their progress that no well developed pneumonia or characteristic focal necrosis of either spleen or liver had developed and no buboes, the animal dying of septicemia in a short time. This is a striking parallel to the course in human cases at the height of the epidemic of 1910 in Manchuria. There, cases were seen in which the lung involvement had not progressed beyond a stage of congestion, the victim dying of a septicemia, the progress of the condition being so rapid that death occurred within twenty-four hours, no glandular involvement whatever being found.

CONCLUSION

I will point out two or three matters that seem obviously to contradict any ideas that may have been previously entertained concerning the simplicity of the problem or its lack of public health importance.

At present there is a lighting up of enzootic plague, which had become a commonplace, into a rather alarming epizootic, which is the most extensive outbreak of squirrel plague since the peak of the epizootic in Contra Costa and Alameda counties in the period between 1907 and 1919. Other sharp outbreaks have doubtless occurred that burned themselves out without the condition being brought to attention in time to prove the nature of the epizootic. The present outbreak, however, has certain aspects that are not entirely reassuring. It is not without significance that after a considerable period of quiescence plague is found to be actively spreading among the wild rodent population of rural areas in widely separated districts and in areas far from any formerly known focus of infection. The prevalence of infected squirrels near the borders of Oregon and of Nevada and on the other side of the mountain range suggests that there is no natural limitation to the spread of plague through wild rodents to places far distant from its original entry into this country in the Bay district of California.³ Plague is very evidently a permanent problem on the Pacific Coast and the prospect of its becoming a problem in other states appears at the present time to be good. Especially to be feared so far as man is concerned is the pneumonic form of the disease, which, as I have already indicated, may be directly related to plague in animals of the squirrel and ground hog type.

³ Rodent plague has been reported by the U. S. Public Health Service, since the writing of this article in the state of Montana and in three counties of Oregon.

Buoyant Health.—More recently, the work of Dalldorf in this country and of Göthlin and of Gedda abroad seems to have shown a definite relation between the vitamin C value of the food and the resulting strength and healthy resilience of the capillary arteries or arterioles. These capillaries allow the escape of blood and the resultant formation of minute subcutaneous blood spots (petechiae) more readily in cases of shortage of vitamin C even when the deficiency is not sufficient for the development of manifest scurvy. Thus even a relative shortage of vitamin C tends to a condition of capillary fragility such as also develops with advancing age and in some diseases. Such observations lend force to the view that liberal intake of vitamin C may be a factor in the preservation of the characteristics of youth and in the development and maintenance of positive or buoyant health.—Sherman, H. C. *Food and Health*. New York, Macmillan Company, 1934.

RECOVERY FOLLOWING JAUNDICE WITH ASCITES

REPORT OF TWO CASES

JOHN McCABE, MD

AND

JAMES FINLAY HART, MD

NEW YORK

Meyer and Learner¹ have recently pointed out the rarity of recovery when jaundice and ascites occur at the same time. They review the rather scanty literature on the subject, give the small number of reports of recoveries on record and report one new case.

In this communication we report two more cases of recovery following jaundice with ascites. We shall in addition discuss our cases and those reported in detail in the literature.

REPORT OF CASES

CASE 1 (reported in August 1933 as a case of cirrhosis helped by insulin²)—Wilfred A., a carpenter, aged 36, was admitted to the New York City Hospital, Jan. 9, 1932, as a transfer from Bellevue Hospital. He stated that early in December 1931 he began to lose his appetite and to become distressed after eating even small amounts of food. About December 15 he became jaundiced. He then entered Bellevue Hospital, where he was given gallbladder dye by mouth. On January 1 he began to vomit and lost about 20 pounds (9 Kg.) by the middle of January.

The patient was well built, and examination revealed marked jaundice, mental dulness and edema of the ankles. The pulse rate was 44 and the blood pressure was 116 systolic and 56 diastolic. There was no ascites or distention. There were no visible masses or rigidity noted on palpation. Pressure over the gallbladder, however, elicited nausea and pain. The edge of the liver was not felt and the spleen also was not palpable. At no time was there diarrhea or bloody stools.

On January 11 an electrocardiogram was normal. The urea content was 20 mg. and the fasting blood sugar was 100 mg. per hundred cubic centimeters of blood. The icteric index was 200, the van den Bergh direct delayed reaction was positive and the bilirubin content was 12.5 units.

On January 12 the benzidine test revealed no blood in the stools. The Wassermann reaction was negative. Because of excessive vomiting the patient was given by vein at 11 a. m. and again at 4 p. m. 300 cc. of a 10 per cent solution of dextrose and 15 units of insulin.

On January 14 the icteric index was 150, the van den Bergh direct and indirect reactions were positive. The bilirubin content was 13 units. The patient was restless and made twitching, clonic movements. The degree of jaundice was increased. The diagnosis was acute hepatitis (subacute yellow atrophy) with early cholemia.

On January 18 the patient was better but the jaundice was still marked. An intravenous injection of 400 cc. of a 10 per cent solution of dextrose was given on January 27. On February 2 the patient was much better and the jaundice was improved, but cirrhosis was suspected. On February 5 there was evidence of ascites and of edema of the legs and scrotum. The icteric index then was 100 and the nonprotein nitrogen content was 30 mg. The van den Bergh reaction was immediate and the indirect reaction was positive. The serum albumin content was 4.3 per cent and the serum globulin 2.6 per cent.

Paracentesis was performed on February 13 and 3,300 cc. of cloudy green fluid was removed. The patient was then placed on a high carbohydrate diet and 5 units of insulin was given twice daily. The insulin was discontinued on February 23. On February 28 it was resumed and given until March 12, inclusive. A second paracentesis was performed on March 8 and 1½ quarts (1,420 cc.) of fluid was removed. The next and last tapping was carried out on March 25 and 3,500 cc. was removed.

¹ Meyer, Jacob and Learner, Aaron. *Ascites Occurring During Jaundice with Recovery*. J. A. M. A. 104:114-116 (Jan. 12) 1935.
² McCabe, John and Hart, J. F. *Treatment of Hepatic Cirrhosis with Insulin*. New York State J. Med. 33:924-929 (Aug. 1) 1933.

On March 28 the icteric index was 35, the van den Bergh direct reaction was immediate and the indirect reaction was positive. On April 2 the icteric index was 20 and on May 25 it was 10. Both van den Bergh reactions were negative.

The patient was discharged on May 26. He had at that time no complaints except tenderness about the region of the liver and a continuous itching over the entire body.

CASE 2—Mrs. R., a housewife, aged 55, had been on a low carbohydrate, low insulin diet for a number of years for diabetes. About Jan. 15, 1933, she was placed on a high carbohydrate diet with 15, 0, 15 units of insulin in twenty-four hours. Her general condition improved. About the beginning of November she sought advice because of recently noted indigestion, manifested by excessive gastro-intestinal fermentation. On November 25 jaundice of the painless type developed. An abdominal examination revealed no abnormality. The jaundice became darker, resembling that seen in carcinoma of the head of the pancreas. On January 1 the feet began to swell and in about a week the abdomen filled up with fluid under great tension. On January 16 the patient vomited dark blood and continued to do so for more than a week. The stools were tarry.

A subsidence of the ascites made tapping unnecessary. Gradual improvement continued but the jaundice did not clear up until the middle of April. Toward the end of the illness the patient stated that she had taken three tablets of cinchophen a day all through the month of September and most of October. Her present condition (two years later) is good.

COMMENT

Both our cases started like ordinary cases of catarrhal jaundice. There was a preliminary period of several weeks of gastro-intestinal symptoms followed by painless jaundice. The first patient became worse shortly after taking gallbladder dye, and it is possible that the dye increased the injury to the liver. The second patient gave a history of taking cinchophen for several weeks preceding the onset of the gastro-intestinal symptoms. There was, therefore, a justifiable cause for yellow atrophy, either acute or subacute.

Definite mental symptoms with restlessness and clonic twitchings were manifest in the first patient, while the second patient showed only mild mental aberrations. Such symptoms, in a greater or less degree, are almost pathognomonic of yellow atrophy and are a reliable clinical guide to its detection.

The jaundice in both cases was present over a long period, each patient giving signs of it for more than five months. This is many times the duration of the average infectious jaundice.

The ascites began in the first patient after seven weeks of jaundice and in the second patient following the sixth week. Toxemia was prominent in the first patient, while the second showed evidence of impairment of the hepatic corollary circulation when the gastric hemorrhage occurred.

REVIEW OF CASES PREVIOUSLY REPORTED

The first case of recovery from combined jaundice and ascites in the available literature was reported by Jones and Minot³ in 1923. From the history this case could have been termed an infectious (catarrhal) jaundice. There was an abrupt unaccountable onset without pain, followed in two weeks by jaundice. During the first four weeks the jaundice varied in intensity. The liver became palpable and tender early and as time went on grew larger. The spleen could be recognized after the liver became definitely enlarged. An exploratory operation showed the evidence of well established

cirrhosis—gross lobules and large bands of fibrous tissue. There was no sign of an obstruction, rather that of a general infection.

Bauer⁴ reported the next two cases in 1926. The first was a typical case of infectious jaundice. Ascites developed and was relieved by tapping. The patient recovered slowly and in two months was well, except that the liver and spleen showed enlargement. Bauer was strongly suspicious of the presence of subacute yellow atrophy in this case.

In his second case jaundice was noted two months after a course of arsphenamine treatment had been completed. When the patient arrived at the hospital he showed some mental symptoms. There was deep jaundice with ascites, and the liver and spleen were definitely enlarged. For thirteen days he was given 20 units of insulin daily and liberal amounts of dextrose. Considerable improvement followed. Several doses of salyrgan were given and the ascites disappeared. The patient was examined six months later and his condition was found to be good except that the liver and the spleen still showed enlargement.

Weir⁵ in 1928 added four more cases to the list. His first case was that of a patient who had partial biliary obstruction for a long time with periods of complete stoppage of bile. Finally, after about eight months of more or less continuous colic in the upper portion of the abdomen, gradual progressive enlargement of the abdomen was noted. There was tenderness in the region of the gallbladder, and the liver was enlarged, firm and somewhat nodular. The symptoms continued for more than eleven months more, during which time there was a slow but progressive enlargement of the liver. The patient was then taken to the hospital for an exploratory laparotomy. The ascites disappeared spontaneously just before operation. When the abdomen was opened, definite evidence of biliary obstruction was found in the form of a large, soft stone in the common duct. The liver was hobnailed and twice its normal size. Ascites occurred four months after operation but soon disappeared.

The next case was one of painless jaundice following two weeks of cinchophen treatment. After two weeks of jaundice there was rapid and distressing enlargement of the abdomen. At this stage neither the liver nor the spleen was enlarged. The ascites responded to the administration of merbaphen and ammonium chloride. The jaundice continued but finally disappeared.

The third case was that of a woman who suffered from a gastro-intestinal upset of apparently short duration followed by deep jaundice. She had no pain or fever. The icterus continued for three months and then cleared up. Ascites developed and required tapping about three weeks after the jaundice disappeared, and again two weeks later. The liver was not palpable at any time and was apparently not tender. The spleen, however, was markedly enlarged. Two months after the last tapping, the ascites had not returned.

The fourth case started with gastro-intestinal symptoms. Drowsiness became marked and in about a month deep jaundice appeared and continued for three months. Just before it disappeared, ascites developed rapidly. About that time there was tenderness at the right costal margin. The ascites responded to ammonium chloride and merbaphen treatment. For six months the patient

³ Jones, C. M. and Minot, G. R. "Infectious (Catarrhal) Jaundice," *Boston M. & S. J.* 189: 531 551 (Oct. 18) 1923.

remained well but then suffered from mild jaundice and some ascites, which responded rapidly to treatment.

Meyer and Learner presented the next and latest case, that of a man in whom jaundice developed after more than a year of gastro-intestinal symptoms. This continued for about five weeks and then started to subside. About that time, however, ascites appeared and progressed to a marked degree in two weeks. Salyrgan was administered for the following two weeks and the ascites disappeared. The liver showed signs of tenderness and was enlarged. The spleen was not palpable. An operation performed after the ascites had disappeared showed a distended gallbladder that was edematous and thickened but not inflamed. The common duct was markedly dilated, though no stones were found. The liver was enlarged. An enlarged gland was found behind the common duct.

COMMENT

A perusal of the etiologic factors in these ten cases, as given, shows a wide divergence. One case was due to arsphenamine, one to a stone, one apparently to the pressure of a gland against the common duct, two to cinchophen, two were infectious, and three had no specific cause but acted like the usual catarrhal jaundice. Though ten cases constitute a small number on which to base a generalization, it is evident from these cases that jaundice with ascites can follow many of the well known causes of hepatic dysfunction.

The prodromal gastro-intestinal period was short in seven of the cases, two to three weeks being the average. In two others it lasted for over eight months. The first of these cases was due to a bivalve stone that caused intermittent obstruction. It is within reason to suspect that in that case and perhaps in the case reported by Meyer and Learner disorganization of the hepatic cells was not complete until a few weeks before jaundice appeared. The period of gastro-intestinal symptoms preceding jaundice was therefore fairly constant in this group.

The jaundice in practically all the cases was of long duration, much beyond that seen in the usual catarrhal type of case.

There was evidence of tenderness of the liver in four of the cases, and five patients showed definite signs of enlargement. In the three cases in which an operation was performed, the liver was found to be enlarged, while in two of the cases there was definite evidence of cirrhosis.

Three types of treatment were given. The etiologic factor was removed in four cases (cinchophen in two, stone in one and an enlarged gland in one). Supportive treatment, high carbohydrate diet and insulin were given in three cases. The ascites was tapped in three cases, organic mercury and ammonium chloride were administered in three, and there was spontaneous disappearance of the ascites in three.

At this time certain questions naturally arise. Why do some patients with hepatic disease have both jaundice and ascites, and why do so few of them recover? Also, what seems to be the reason for the favorable results herein described?

We shall first consider why some patients with hepatic disease present jaundice and ascites. We cannot account for the simultaneous occurrence of these two signs from an etiologic standpoint, for we have just shown that this syndrome followed each of the well known causes of hepatic disease. We suspect, however, that the intensity of the irritation coupled

with its duration regulates the presence of jaundice or of ascites, or of the two together. For example, one notes cases of common infectious jaundice with a mild course followed by complete recovery in a few weeks, while at the other extreme, in a case of acute yellow atrophy there is rapid stormy progress to death. Yet one is familiar with an intermediate course pursued in certain cases in which the symptoms are suggestive of subacute yellow atrophy and in which, after a more or less prolonged duration, cirrhosis appears.

Of the ten cases reviewed, seven easily fall into the group showing subacute yellow atrophy and hence suggest a moderately severe irritation. The three others, cases 3, 6 and 10, showed definite evidence of prolonged cellular dysfunction by the jaundice, which lasted for four months, nineteen months and more than five weeks, respectively. In the last case, 10, in addition there was a history of irritation of the liver for over a year. Hence, in this series every patient showed either moderately severe irritation or prolonged jaundice or both.

Summary of the Ten Cases Reported

Etiology	Prodromal Period	Duration of Jaundice	Condition of Liver	Treatment
Obscure, dye (?)	2 weeks	Over 4 mos	Edge not felt	Dextrose insulin tapped
Cinchophen	3 or 4 weeks	Over 4 mos	Normal	High carbohydrate diet insulin
Infectious	2 weeks	Over 4 mos	Tender and palpable at operation gross lobules large fibrous bands found	Not stated
Infectious	About 2 weeks	Not stated	Enlargement continued	Not stated tapped
Arsphenamine	Questionable	Not stated	Enlargement continued	Dextrose insulin
Bivalve stone	Over 8 mos	Intermittent long period	Tender enlarged firm nodular at operation found to be bivalved twice normal size	Stone removed
Cinchophen	Short time	3 months	Normal	Cinchophen stopped
Obscure	Apparently a short time	3 months	Normal	Not stated tapped
Obscure	3 weeks to 1 month	3 months	Tender	Not stated
Obscure	Over 1 year	Over 6 weeks	Tender and enlarged	Operation a possible aid

The presence of ascites in each of these cases is excellent evidence that the stage of cirrhosis had arrived. Further proof was apparent in several cases. Gastric hemorrhages were suggestive of an engorged coronary circulation in case 2, and in cases 3 and 6 definite evidence of cirrhosis was found at operation.

In the ten cases reviewed in this communication, definite signs of jaundice were present before the ascites occurred. There is a common type of hepatic disease in which the ascites appears as the first clinical sign. This is usually called portal cirrhosis, and it is noted for the fact that it is rarely, if ever, accompanied by jaundice even in its final stages. The exact cause of the condition is not known, but it is generally accepted to be the result of mild long continued irritation.

From the observations in these cases one may say that the etiology is no guide to an explanation of the presence of both jaundice and ascites. Any moderately

severe irritation, however, that was present for a prolonged period brought about jaundice that was followed by cirrhosis

One is interested to know why so few patients with jaundice and ascites recover. It has long been recognized that ascites is a terminal sign of hepatic disease. In fact, the majority of students of hepatic ailments have long held that once ascites appears the patient is doomed. However, an occasional case of recovery has been reported and the ten cases gathered together here may also be considered as instances of recovery after ascites has appeared. Clinical experience and pathologic studies have shown that ascites in hepatic conditions is an exhibition of an advanced stage of cirrhosis. It is the sign of a decompensation of the organ after an extensive change in its architecture has been completed. When such a pathologic stage has been reached, it is remarkable how any patient can recover.

Finally, one would like to know why in these cases favorable results are obtained after such a dangerous stage has been reached. On analysis one notes that in four cases the etiologic or irritating factor could be determined and was thereby removed or stopped. The stone was a concrete and measurable factor, while the arspenamine and the cinchophen, though measurable in the introductory doses, could not be assayed for their toxins. Clinical experience and pathologic studies, however, show that both of these drugs, when they pass the threshold of safety, act intensely on the liver. Two cases were diagnosed as resulting from an infection and the four others gave no positive evidence of their etiology and for that reason might well be classed with the infectious type. In the last six cases then the etiologic factor was an irremovable type of irritant. It is within reason to assume that there was a similar causal factor and that it closely resembled the causal factor present in cases of common benign infectious jaundice. Then if this assumption is true, one is dealing with a factor which in the vast majority of cases is self limited. Just as there are mild types of infectious jaundice, there may well be severe and prolonged ones. Following this reasoning, it is possible that the patients who recovered without any outside aid did so because the toxin involved wore itself out just at the point where the liver became decompensated. Then, in the other cases in which help was given, such help may have turned the tide. This may account for the favorable outcome in cases 1, 2 and 5, in which insulin and dextrose were employed.⁶

IMPRESSIONS

1 Jaundice with ascites may follow any known type of irritation to the hepatic cells

2 The intensity of the irritation coupled with its duration regulates the degree of jaundice or ascites or both

3 A moderately severe injury to the hepatic cells prolonged over many weeks produces subacute yellow atrophy

4 Subacute yellow atrophy continued for a number of weeks produces cirrhosis

5 An irritant intense enough to cause subacute yellow atrophy, and prolonged enough to bring about cirrhosis, will within a reasonable time, if it continues to act, cause the cirrhosis to reach the ascitic stage

6 It is evident that the removal of the etiologic factor is essential when possible. If the irritation is

intense or if it has acted for a long time before it is removed and if the factor is undeterminable, auxiliary measures should be employed. These consist of the administration of dextrose, insulin and cholagogues and biliary drainage.

THE ETIOLOGY OF VULVO-VAGINITIS INFANTUM

A. CHARLOTTE RUYSS, MD

AMSTERDAM, HOLLAND

In cases of children suffering from vulvovaginitis, the first question is whether or not it is a gonorrheal infection. The clinical picture of this infection is not typical enough to allow a diagnosis to be made without a bacteriologic examination. The diagnosis is almost always made on smears of the pus stained by Gram's method or only with methylene blue. Cultures are not considered necessary. As there are some cocci that resemble the gonococci more or less when different staining methods are used, the way to a faulty diagnosis is open. Clauberg¹ pointed out that many cases of vulvovaginitis were falsely considered gonorrheal infections. From seventy children with vulvovaginitis he could not cultivate gonococci. Gradwohl^{1a} cultivated gonococci in only two out of twenty-five cases. As I had found the ascites-Levinthal-agar plates and blood-water-agar plates excellent mediums for the isolation of gonococci, I tried to find out which part this microbe plays in the vulvovaginitis of children.

TECHNIC

All smears are stained by van Loghem's² Gram method. In this method the material is evenly and thinly spread on a slide and fixed by heat. Then it is stained with carbol-gentian violet for five minutes while it is warmed a little every minute (to nearly 37 C). The stain is poured off and the film is treated with compound solution of iodine for forty-five seconds. The iodine is poured off and the film is decolorized intensely in 96 per cent alcohol for exactly thirty seconds. When some part of the film is too thick, it must be removed mechanically during decolorization. After this, the film must be rapidly rinsed in water and counterstained with a watery fuchsin solution.

For the isolation of gonococci I used Levinthal-agar plates with 20 per cent ascitic fluid and a modified blood-water-agar medium of Bieling, which was prepared as follows. Blood drawn from the vein of a horse into distilled water, equal parts, is kept at 60 C for thirty minutes. Two parts of this fluid are mixed with three parts of 2 per cent nutrient agar.

VULVOVAGINITIS GONORRHOICA

In the course of a few years I examined 292 children with vulvovaginitis. I could demonstrate by the culture that only fifty-seven were suffering from gonorrhea. These fifty-seven were all patients with a severely acute inflammation of the vulva and vagina with an abundant secretion of yellow mucopus. In the films of the pus colored with the Gram method of van Loghem I invariably found the typical gonococci. In the acute stage

2 van Loghem J. J. Nederl. tijdschr. v. geneesk. 76: 2193 (May 7) 1932.

of the disease neither the culture nor the smears ever failed to show the gonococci. On several occasions only after the patients had been treated for a long time and the clinical symptoms had disappeared did I get positive cultures when no more gonococci could be demonstrated by microscopic examination. Very rarely did an overgrowth of other bacteria spoil the cultures, as is shown in the following smears taken from the vagina: smears positive, culture positive in 111, smears negative, culture positive in fourteen, smears positive or doubtful, culture negative in seven.

Several German authors describe a gonorrheal infection of the rectal mucosa in children suffering from genital gonorrhea. Their figures as to the frequency of this complication differ widely, but as they are always founded on microscopic examination alone they are never convincing. Dietel³ made smears from the mucus he found on the surface of the feces and got almost 100 per cent positives. Temesvary⁴ obtained his material with a rectal curet and got 28.9 per cent positives. The method of Glingar⁵ of rinsing the rectum and looking for flocks of mucus in the water is now used by several workers. Only Joachimovits⁶ and Bloomberg and Barenberg⁷ tried to grow the gonococci from the rectum. They did not use the best mediums and so their experiments were not successful enough for this method to be used in routine practice.

I tried to make the diagnosis by cultivation on the mediums mentioned. After I had tried in vain to obtain the right material by the rinsing method I succeeded very easily by taking it directly from the rectum by scraping softly along the mucosa with a strong loop while the anus was held open by an assistant. With this method I could grow the gonococci from the rectum of every child who suffered from genital gonorrhea.⁸ Up to the present I have examined the rectum of thirty-eight children with this infection. The direct examination of smears from material from the rectum also often reveals typical gonococci, but in most cases it is rather difficult to make a diagnosis, and on several occasions the smears were negative with a positive culture: smears positive or doubtful, culture positive in forty-nine, smears negative, culture positive in sixteen, smears positive, culture negative in five.

The children never complain of pain or other symptoms. Formerly nothing had attracted my attention to this complication. But although the course of the infection is very mild it is also very obstinate, and in most cases it withstands treatment for a rather long time.

Of these fifty-seven children with gonorrhea, only three suffered from other complications, namely, one from conjunctivitis, one from cystitis and one from a pelvic inflammation, probably a salpingitis. In women with genital gonorrhea I also succeeded in growing gonococci from the rectum, but not in such a high percentage. From sixty-nine women with genital gonorrhea I found forty-three positive at the first examination, of these, forty-two were found by the culture method. The smears were positive only twelve times and in nine cases they gave a doubtful result.

As for the chronic form of this disease, in an experience of several years I never met a nontreated case of chronic vulvovaginitis caused by gonococci. I believe that vulvovaginitis gonorrhoea occurs only in the acute form and can be compared in this respect to the gonorrheal conjunctivitis. All the children were cured after from four to eight months' treatment. Only once did a child have a recurrence or reinfection after treatment.

Since the diagnosis in children with vulvovaginitis is made by van Loghem's Gram method combined with the culture method, the number of children treated for vulvovaginitis gonorrhoea in the Amsterdam hospitals has been reduced from approximately 450 a year to twelve a year.

NONGONORRHEAL FORMS OF VULVOVAGINITIS

Some of the children in whom no gonococci were found were suffering from an acute inflammation, others complained of a more chronic state of irritation with a varying degree of secretion. In most of the cases the faulty diagnosis of a gonorrheal infection had been made in other laboratories on smears colored with a Gram method in which the films had been decolorized too much. I always use the method of van Loghem, already described, in which decolorization is done in exactly thirty seconds. In a rather long experience with all possible bacteria, it proved an excellent staining method. In the nongonorrheal cases of vulvovaginitis it gave far fewer difficulties than most other methods. With van Loghem's method, most cocci from the vagina are gram positive, the gonococci and occasionally some other cocci are gram negative.

In a large series of experiments I tried to alter the gonococci into gram-positive ones, but without success. Neither could the gram-positive cocci from the vagina of children be transformed into gonococci. There is no reason to believe that gonococci can become gram positive.⁹

With the other Gram methods many vaginal cocci are also gram negative, and these are often mistaken for gonococci. In nearly every infection of the vagina these cocci are found. In the acute gonorrheal form they almost disappear, but in several chronic forms they dominate the field with or without other microbes.

The nongonorrheal vulvovaginitides can be divided into two groups: the acute forms and those which are chronic from the onset.

ACUTE FORMS

Vulvovaginitis Scarlatinea.—Now and then during scarlatina or in the course of convalescence an acute inflammation of the vulva and vagina is seen with a seropurulent secretion. In the smears, gram-positive diplococci prevail within or outside the leukocytes. On the blood-agar plates, colonies of hemolytic streptococci grow in an almost pure culture. This complication of the scarlatina often clears up without treatment in a few weeks. In a few cases it took nearly six weeks before the infection had gone. Even in the acute stage the infection was invariably less severe than the gonorrheal form.

Over a period of a year I examined weekly all patients with scarlatina in one ward of the Wilhelmina Gasthuis at Amsterdam. In the vagina of five out of sixty-six patients I found hemolytic streptococci. Only one patient had an almost pure culture of these cocci, and this child was the only one who was suffering from

a real vulvovaginitis scarlatinosa. From 378 children in the hospital with scarlatina in the course of one year, only five suffered from this complication.

Vulvovaginitis with Influenza Bacilli—In several patients with an acute vulvovaginitis I found a seropurulent secretion with many fine gram-negative bacilli. On blood mediums many colonies of *Hemophilus influenzae* with all its typical properties were isolated. The smears always contained other bacteria and cocci, the influenza bacillus never growing in a pure culture. In a few cases this infection was accompanied by fever lasting a few days. In the cases that I could follow this infection cleared up very soon without any treatment.

Diphtheria of the Vulva—In one patient I found the vulva swollen and bluish, with a gray membrane on the vaginal wall. The child was feverish and complained of severe pain when urinating. The films of the exudate contained many gram-positive bacilli. In culture and animal experiments it proved to be a toxic strain of diphtheria bacilli. After serum treatment the pain and other symptoms diminished and soon the child made an undisturbed recovery.

CHRONIC FORMS OF VULVOVAGINITIS

In many cases of vulvovaginitis there is no history of an acute disease. The children suffer from a chronic state of irritation with a varying degree of secretion. They often look pale and complain of vague abdominal pains. Locally there is no severe inflammation. The vaginal wall is red but not swollen, a seropurulent secretion sometimes giving rise to a little redness of the labia. The films and cultures from the pus show different bacilli and cocci in varying quantities. A few times nearly pure cultures of pneumococci were found, which were virulent for mice. Two of the strains belonged to types XIX and XXII. In most cases mixed cultures of different microbes were obtained, namely, *Staphylococcus albus* and *aureus*, *Diplococcus crassus*, hemolytic and green producing streptococci, *Bacillus coli*, *B. proteus*, diphtheroids and once *Neisseria catarrhalis*.

It is difficult to conclude whether these microbes play a role in the etiology of the disease or are merely secondary invaders. Roscher¹⁰ states that constitutional diseases such as exudative diathesis, anemia, scrofulosis, asthenia and also masturbation cause vulvovaginitis. The success of hospital treatment with children suffering from chronic vulvovaginitis is probably due more to the improvement of the general health conditions than to the local treatment. In contrast to the gonorrheal form, which can always be cured by local treatment, these children suffer from an infection that often withstands treatment as long as the general conditions do not improve.

Attention must be paid to the fact that sometimes foreign objects can give rise to symptoms of a more or less severe vulvovaginitis. Once I found a large safety pin and two beads. *Oxyuris vermicularis* may also act as a foreign body in the vagina and give rise to irritation. In these cases the cleaning of the vagina is followed very soon by complete recovery.

SUMMARY

In many cases of vulvovaginitis the etiologic diagnosis can be made only by means of the culture method. For the examination of smears, van Loghem's Gram method gives the best results.

Vulvovaginitis gonorrhoea occurs only in the acute form. Every case of vulvovaginitis gonorrhoea is complicated by gonorrhea of the rectum.

In other forms of acute vulvovaginitis, hemolytic streptococci, influenza bacilli and diphtheria bacilli play a role.

In chronic vulvovaginitis, probably the primary cause is a constitutional disease.

POOLED CONVALESCENT SCARLET FEVER SERUM TREATMENT

OF DIVERSE STREPTOCOCCIC INFECTIONS

WILLIAM THALHIMER, MD

AND

SIDNEY O. LEVINSON, MD

CHICAGO

Not infrequently one encounters a severe or fulminating hemolytic streptococcus infection that does not yield to the accepted methods of treatment. The infection progresses, the patient goes steadily downhill, and the physician realizes that all his efforts have been futile. Under these conditions the physician searches for additional aid in treating his patient.

Our interest in this clinical therapeutic problem was aroused by physicians asking the Samuel Deutsch Convalescent Serum Center for possible help in combating these violent streptococcic infections. We did not have any serum from individuals who had recovered from such infections because it is manifestly impossible to secure an adequate supply of serum from these patients. Since we had available two types of pooled convalescent streptococcus serum, i. e., pooled convalescent scarlet fever and pooled convalescent erysipelas serum, we thought under the circumstances that they were well worth a therapeutic trial.

Apparently there is no sharp line of differentiation between many cases of fulminating streptococcic infections and certain types of septic or complicated scarlet fever. The clinical picture in many instances is identical, with the exception of a rash. In the former there may even be a local or general erythema resembling a true scarlet fever rash. This marked similarity between these two clinical conditions is an outstanding feature. Besides the clinical resemblances of these various infections to one another there are bacteriologic and immunologic resemblances of the strains of streptococci obtained from such multiform infections to those obtained from scarlet fever throats.

In our experience with the routine use of pooled convalescent serum in scarlet fever we had occasion to observe the beneficial effects of such therapy in late septic or complicated cases.¹ Frequently there occurred diminution in fever, alleviation of toxemia and prostration, and cessation or regression of a steadily advancing infectious process. At times these changes followed rapidly and quite dramatically.

It was these similarities and results that prompted us to recommend a trial of pooled scarlet fever convalescent serum for various streptococcic infections.

Recognition of the very slight and brief immunity developed by an attack of erysipelas, coupled with our experience of the inadequate therapeutic response of this disease at times to its own convalescent serum,

¹⁰ Roscher in Jadassohn, Joseph. *Handb. d. Haut u. Geschlechtskr.* Berlin: Julius Springer, 1933.

From the Samuel Deutsch Convalescent Serum Center, Michael Reese Hospital, 1 Hoyne Ave., Chicago. *Illinois Health Messenger* 7: 49 (No. 5) 1935.

made us feel doubtful of obtaining sufficient benefit from convalescent erysipelas serum in these other types of streptococcic infections. Nevertheless, a trial of this serum was made until it was learned that scarlet fever convalescent serum was more effective.

Since, in our hands, human serum, administered by any route, has been an innocuous substance and has not produced foreign protein reactions or sensitization, we felt safe in recommending this form of therapy. Therefore, even if no benefit should be derived, at least no harm would be done to the patient.

Since the latter part of 1931, when this work was begun, the serum has been employed by many physicians. Although most physicians had occasion to use it for treating only one or two patients, others employed it in a larger number.² They all appreciated the fact that it was a clinical therapeutic trial and maintained an attitude of impartial observation or even of skepticism. We believe, therefore, that the results reported to us are highly significant, because these reports come from many physicians independently studying their own cases and uninfluenced by the opinions of others. Their conclusions were based only on their own observations in the course of their own practice.

Killian,³ who has reported convalescent scarlet fever serum treatment of a number of patients with streptococcic sepsis, came to the conclusion that in some instances these patients improved remarkably after such therapy. Boente⁴ also reported with regard to the favorable effect of convalescent scarlet fever serum on the toxemia of patients with streptococcic infections.

Recently Baum⁵ has reported a number of extremely interesting cases. He secured serum from patients recently recovered from scarlet fever or from severe streptococcic infections, most of the serum being obtained from recovered scarlet fever patients. He did not pool the serum but preserved each individual serum separately. He determined the agglutination titer of the serums he had in stock against the streptococcus he had isolated from the patient to be treated. He chose for his therapeutic serum the one that had the highest titer of agglutination and obtained in many instances an excellent therapeutic response. He felt that in his small group of cases there was a correlation between the therapeutic response and the agglutination titer. In a few instances, when a serum of low titer yielded no results, the use of serum with a high titer was followed by a satisfactory response.

Our report is based on a study of 122 patients. This group is made up of a large variety of streptococcic infections, all the patients having been severely ill, the infection not having yielded to other forms of therapy. The following number of cases and conditions were treated: cervical adenitis following a streptococcic sore throat, twenty-eight; sepsis⁶ and septic complications, twenty-six; acute streptococcic pharyngitis, twenty-three; purulent otitis media, ten; streptococcic meningitis, seven; streptococcic phlegmon, six; streptococcic tracheobronchitis, six; streptococcic pneumonia, three; acute vegetative endocarditis, three; streptococcic arthritis, three; "sepsis" with possible streptococcic peritonitis in patients with chronic nephritis, two; acute nephritis and cervical adenitis as a complication of a

streptococcic sore throat, two; streptococcic lymphadenitis, one; streptococcic peritonitis, one; and streptococcic osteomyelitis, one.

As was stated previously, practically all the patients were treated with pooled convalescent scarlet fever serum, because of the general impression that the erysipelas serum was less effective, although in a few instances some benefit was reported with the use of the latter serum. Each pool was a mixture of the serum obtained from fifteen to thirty recently recovered adults. Since at each bleeding about 225 cc of blood was taken, yielding about 100 cc of serum, the pools varied from 1,500 cc to 3,000 cc. The serum is processed strictly according to the regulations of the United States Public Health Service, and under a federal license from this department. The serum was administered in doses of from 20 to 100 cc. It was soon found that, because of the virulence of the infection, large doses were necessary. When the desired effect was not obtained promptly from a single injection, we did not hesitate to recommend a second and a third dose at intervals of from twelve to twenty-four hours. Usually the serum was administered intramuscularly, because conditions in the home were not always suitable for intravenous therapy. Whenever possible, the latter route was employed because of the more rapid response obtained.

A comparable untreated group for control purposes could not be collected because of the diverse conditions encountered and also because each request for convalescent serum was for use in patients so severely ill that the request had to be granted. Therefore, one must depend for an evaluation of the results on the usual experience with these types of infections.

In 11 per cent of the cases treated, the response was considered excellent. This term was employed when there was a critical termination of the infection, with marked decrease in fever and prostration and cessation of the disease process. In 44 per cent a good effect was reported. This term was used to designate a somewhat slower but nevertheless definite and progressive improvement leading to complete recovery. This gives a total of 55 per cent of the patients who were undoubtedly benefited by serum treatment.

In 17 per cent the results were recorded as doubtful, for although the patients eventually recovered the evidence was not sufficiently clear to indicate what role the serum may have played. In the remaining 28 per cent no detectable improvement followed the use of serum and no effect was reported. Of the thirty-four patients making up this group, twenty-three died. Of the patients who died, eight had "sepsis" and septic complications, seven had streptococcic meningitis, three had acute vegetative endocarditis, two had severe streptococcic cellulitis, one was suffering from a mediastinitis that followed an acute streptococcic pharyngitis, one had a streptococcic pneumonia and one had a streptococcic peritonitis.

It is of interest that the group diagnosed as "septic with septic complications" consisted of twenty-six patients, only eight of whom died, the other eighteen patients recovering. However, although all the patients with streptococcic meningitis and streptococcic endocarditis succumbed, we still believe that early cases should not be denied treatment with extremely large amounts of convalescent scarlet fever serum, which might help in an occasional case.

It is impossible to give a graphic picture of the results in tabular form, and limitation of space will not permit

a record of each case. Therefore, short abstracts of a few striking, yet characteristic, cases will be presented, although there are many similar reports in our records.

CASE 1—A boy, aged 2 years, became acutely ill with sore throat and cervical adenopathy three weeks before admission to the hospital. There had been a high, septic temperature during this entire period. For the week prior to entrance he had eaten no food and had taken liquids in small amounts only. The morning of admission the uvula became so edematous that it was necessary to make several punctures to permit adequate breathing and swallowing.

On examination the patient was extremely toxic, responding to nothing in his environment, refusing food or liquids, and lying relaxed and semistuporous. The throat was fiery red and the uvula edematous. The cervical glands were enlarged on both sides, but the swelling on the right was tense and extremely hard, so that it was not felt that incision was practicable at the time. Throat culture revealed *Streptococcus haemolyticus* and *Streptococcus viridans*. Otherwise the examination was negative.

Because of the severe intoxication it was thought advisable to inject 60 cc. of convalescent scarlet fever serum intravenously on the morning of entrance. By late afternoon the patient was talkative and willing to take fluids and nourishment and was sitting up in bed of his own volition. The temperature remained high but was modified. Two days later the glands were incised, following which recovery was uneventful.

CASE 2—An intern at the hospital contracted a severe throat infection with high fever and severe swelling of the glands of both sides of the neck. He became extremely toxic from the start. On the second day the throat became so edematous that breathing was difficult and he had to be fed continuously by tube. The condition became so severe that continuous intravenous dextrose was administered.

On the second day 20 cc. of convalescent scarlet fever serum was given intravenously (100 cc. had been advocated). No improvement was noted, so on the third day 80 cc. of the same serum was given in the same way. Improvement was immediately seen in the temperature and in subjective feelings. The patient stated that he felt better within an hour or two after the injection. Convalescence was uninterrupted.

CASE 3—A child had a severe streptococcal throat infection, complicated by a bilateral cervical adenitis and a cellulitis of the face, neck and scalp, with suppuration of the glands, spiking temperature and marked prostration. Convalescent serum was administered as a last resort, and in thirty-six hours there was definite improvement evidenced by lower temperature and improvement of the cellulitis. From then on, there was complete recovery.

CASE 4—A boy, aged 5½ years, had been ill for two weeks before admission to the hospital. For one week following a mild infection of the upper respiratory tract there was a marked bilateral cervical adenitis and septic temperature. When the glands subsided, a cough developed and the temperature remained high. The urine was cloudy and contained blood. Two injections of antistreptococcus horse serum were administered, but no improvement occurred.

On admission to the hospital the child was severely prostrated, with a purulent sinusitis, beginning right otitis media and manifestations suggestive of a bilateral bronchopneumonia. The urine contained ++++ albumin and many red and white cells and casts. The nonprotein nitrogen was 63, creatinine 2.2.

For the next four days the condition remained critical, the temperature ranging from 98 to 105 F daily. One blood culture was negative. On the fourth day of hospitalization 20 cc. of scarlet fever convalescent serum was administered intramuscularly. There was a very brief temperature rise to 103.4 F six hours after the serum was given, the temperature then dropping to normal within two hours. The patient seemed improved and brighter. The maximum temperature the following day was 100.4 F rectally and after forty-eight hours was entirely normal. The urinary complications rapidly cleared and the patient made an uneventful recovery.

CASE 5—A boy, aged 7 years, had a sore throat with vomiting, diarrhea, high fever and marked prostration. A faint

atypical rash was present. The toxicity increased and the patient became stuporous. On the third day 40 cc. of scarlet fever convalescent serum was injected intramuscularly. Improvement was marked within eight hours. The temperature subsided and the patient recovered.

We used pools of convalescent scarlet fever serum rather than serum from individual patients for the following practical and theoretical reasons. It was practical to use pooled serum because we always had it in stock and available for immediate use, and the results seem to have justified this. The theoretical reason was arrived at in the following way. It is known that, even though various strains of scarlet fever streptococci differ in many ways from one another, their resemblances are more marked than their differences. Because of this we believed it probable that a pool of the serums from fifteen to thirty patients would contain immune substances to enough separate strains of streptococci causing scarlet fever in a given year to have therapeutic value in most, if not all, of the cases in the same year. This is similar to using representative, recently isolated, strains of meningococci for producing potent therapeutic antimeningococcus serum in horses. It seems to us that the same reasoning holds for using these pools of serum for treating patients with various infections caused by hemolytic streptococci which may be related to scarlet fever strains of streptococci.

We believe that the agglutinin titer of a serum is not necessarily an index of its therapeutic potency. That the determination of known and measurable antibodies is not always an accurate criterion of a serum's therapeutic potency is borne out by the fact that pooled scarlet fever convalescent serum, though lower in antitoxin content than the artificially prepared horse serum as measured by the skin test against the specific toxin, nevertheless appears to contain enough antitoxin and other immune substances to render it extremely potent in treating scarlet fever.

We have no definite information as to the manner in which the serum acts to overcome the infection, whether by antitoxin, agglutinins, bacteriolytins or other immune substances that we cannot detect at the present time with our established laboratory procedures. In some of the patients who did not respond promptly and satisfactorily to convalescent scarlet fever serum we supplemented the therapy with direct whole blood transfusions from donors who had recently recovered from scarlet fever. This was done because of the general belief that whole blood has a greater antibacterial action than serum. We have not had the opportunity to observe a sufficient number of cases to draw any definite conclusions. We have, however, the impression that such transfusions are a valuable adjunct to convalescent serum therapy and may be combined with it. If convalescent serum is not obtainable, immune transfusions should be used, and, as in scarlet fever, may give good results.

In evaluating pooled convalescent scarlet fever serum therapy of diverse progressive hemolytic streptococcus infections, which clinically are neither scarlet fever nor erysipelas, adequate consideration must be given to the type of cases. It should be emphasized that these infections were severe or fulminating, usually having a grave prognosis. Significance can be attached to the definite improvement and recovery observed in 55 per cent of the patients and to a mortality rate for the entire group of only 19 per cent. We believe, therefore, that this form of therapy should be given serious consideration.

ERGOTAMINE TARTRATE IN THE PUERPERIUM

M G DERBRUCKE, M D
BROOKLYN

In order to reduce maternal morbidity and mortality, any means to such an end is worthy of a just and fair trial. The results of one such attempt are herein submitted.

After an initial change in size and shape following expulsion of the placenta, the uterus undergoes but little change in the next forty-eight hours. The measurable mass above the symphysis varies from 12 to 15 cm in width, while the canal measures 15 or 16 cm in depth.¹ The cavity is filled with blood clot, remnants of the spongy layer of the decidua and pieces of membrane. The walls of the uterus are the seat of many large patent sinuses in the various stages of collapse and thrombosis. Obviously, if this excellent bacterial habitat is reduced in size and if the fertile cultural mediums are expelled early, it does not seem unreasonable to expect a reduction in the maternal morbidity.

In a previous report² I have shown that the oxytocic action of ergot, and more particularly its alkaloid, ergotamine tartrate, lessened the chances of postpartum infection by hastening involution. In part at least the results were comparable to those independently arrived at by Rech and Raber.³

TABLE 1—Birth Weights

Weight, in Grams	Percentage
Under 2,250	5.3
2,250 to 3,600	63.6
3,600 to 4,000	22.2
4,000 to 4,500	7.6
4,500 to 5,000	1.3

The present study represents a review of an additional 400 puerperas who received a routine course of ergotamine tartrate. There were twice as many multiparas as primiparas. Three sets of twins were delivered. There were 315 occipito-anterior, sixty-four posterior and twenty-one breech presentations in this series. Nine infants were delivered with the aid of low forceps and one with midforceps, and there were five breech extractions, one after bag induction, and one cesarean section. Manual removal of the placenta was necessary in one case. There was an operative incidence of 4.25 per cent. Over 31 per cent of the infants weighed between 3,600 and 5,000 Gm.

The plan pursued in this series was as follows:

1 Immediately after delivery of the placenta, 1 ampule (about 1 cc) of ergotamine tartrate was administered hypodermically.

2 Beginning with the first day post partum and during the succeeding three days, each patient was given orally 50 minims (2 cc) of the alkaloid solution daily in doses of 6 minims (0.4 cc) each, given between the hours of 6 a m and 10 p m, so that all medication was taken during the patient's normal waking hours.

3 Each day, beginning with the first day post partum and thereafter during the patient's hospitalization, the

height of the fundus was measured, the character of the lochia noted and the highest of the temperatures taken every fourth hour charted on a special form.

INVOLUTION

The uniformly small size of the uterus became apparent at once. Although the extremes were 5 and 18 cm, the average height the first day was 11.82 cm. Involution thereafter proceeded steadily. On the tenth day the fundus in every case was less than 1 cm above the symphysis. In the multiparas the average height was 0.4 cm and in the primiparas 0.9 cm.

LOCHIA

The lochial discharge was in keeping with the progress in uterine involution. At the time the patient left the hospital the lochia was recorded as being moderate in amount in 144, or 36 per cent, scant in 206, or 51.5 per cent, absent in 36, or 9 per cent, and unreported in 14, or 3.5 per cent. In over 60 per cent of

Average height of the fundus for ten days post partum

all cases the lochia was either absent or nearly so. The character of the lochia in those in whom it was still present was rubra in 33 per cent, serosa in 56.5 per cent and alba in 10.5 per cent. In only three cases was it foul. Certainly such observations belie any spastic contractions of the uterus.

A comparison with the control cases of the previous series discloses that (1) some form of lochia was present in all control patients at the time they left the hospital, (2) in only four was it termed scant and (3) lochia rubra was present in 79 per cent.

TEMPERATURE

The indication for the existence of morbidity, however, is neither the height of the uterus nor the type and amount of lochial discharge, but the elevation of the temperature. Herein lies the much debated question: When is a patient considered to evidence morbidity? The nationally accepted standard is the one adopted in 1923: a rise in temperature to 100.4 F on two successive days other than the first day is considered

to be evidence of morbidity. The British are slightly more critical, their standard being 100 F on two successive days other than the first. De Lee has expressed the opinion that a temperature of 100 F on any day should be considered as a sign of morbidity. Perhaps he is somewhat too severe in asking for a classification of all first day temperatures as evidence of infection, and therefore of morbidity. It is generally believed that the usual response to a sudden flooding of the

TABLE 2—Maternal Morbidity in Four Hundred Patients

* The corrected morbidity rate according to American standards was 2.25 per cent (nine patients).

system with a foreign protein is that of an initial rise in temperature, and such a condition may prevail at the time of parturition.

Table 2 shows the uncorrected morbidity rate in the present series according to the accepted American, British and De Lee standards. De Lee's standard has been subdivided to show those patients with only first day temperatures of 100 F or over, and those with one day of temperature of 100 F or over occurring on any other day but the first.

The morbidity in this series, judged by any or all of the aforementioned classifications, I feel, compares quite favorably with that in other series. Among the fifteen febrile patients, as judged by the American standard, were two with acute mastitis, one with acute pharyngitis and rhinitis, one with influenzal pneumonia (admitted in that state), one with pyonephrosis, one with toxemia of pregnancy, admitted with a temperature of 101.4 F, five with sapremia, three with acute endometritis and one with an infected perineal wound. The first five of these patients obviously did not show an obstetric morbidity, and the sixth, although having an obstetric complication, was admitted in a febrile state. If these patients are omitted from the series, the corrected morbidity is only 2.25 per cent. I believe that this is a fairly good showing.

COMMENT

The immediate administration of a suitable oxytocic that will maintain the tonicity of the uterine musculature may obviate the low grade, morbid temperatures which so often are classified as sapremia. In most delivery rooms it is customary to administer from 0.5 to 1 cc of solution of pituitary after expulsion of the placenta. It is known that the action of solution of pituitary is short lived. If a reasonable tonus of the uterus can be maintained for an extended period of time, the chances for the accumulation of blood clot and decidual remnants is greatly diminished.

That a mildly tonic contraction of the uterus is maintained for a longer period with 1 cc of ergotamine tartrate than with solution of pituitary is evidenced by a comparison with the series of 167 patients who received 1 cc. of solution of pituitary hypodermically immediately after expulsion of the placenta. None received the ergot derivative in this stage. The average height of the fundus in all of these cases on the first

day was 151 cm. On the other hand, in the current series, wherein 1 cc of ergotamine tartrate was almost universally replaced by solution of pituitary, the average height on the first day post partum was 118 cm.

Theoretically, at least, it would seem that the cultural mediums in the uterine canal and the gaping sinuses are reduced to a minimum. The continuation of the mildly tonic contraction is maintained during the succeeding three days by the oral administration of the oxytocic in small doses.

The absence of foul lochia bespeaks the absence of sapremia. It would seem that with the decrease in the size of the uterus, undoubtedly at the expense of the cavity, both the "soil and the pathway" for the propagation of an infection are materially reduced, thus lessening at least one possible source of infection. In the present series it was possible to reduce the morbidity in this way to 2.25 per cent.

CONCLUSION

Four hundred parturient patients were given ergotamine tartrate hypodermically immediately after delivery of the placenta and orally for the ensuing three days. It is hoped that a means has been presented for reducing the controllable maternal morbidity. It is felt that any method that will help, however slightly, to carry a parturient woman safely through the lying-in period is worthy of a trial.

THE SPECIFIC TREATMENT OF
LOBAR PNEUMONIA

A STATISTICAL REVIEW

WILLIAM P. BELK, M.D.

Instructor in Clinical Biochemistry, University of Pennsylvania
Graduate School of Medicine
ARDMORE, PA.

The specific treatment of lobar pneumonia was attempted as early as 1897 by Washbourn.¹ His and other early attempts were not successful, because the serums were not made and given on a type specific basis. Since 1913 Cole² has used an unconcentrated horse serum in type I pneumonia with a mortality of 10 per cent. This unconcentrated serum, however, has not become popular because of its tendency to produce reactions.

In 1921 Huntoon³ produced a serum-free solution of pneumococcus antibodies in modified Ringer's solution. The potency of this product is such that it protects mice against 1,000,000 lethal doses of a virulent culture of pneumococcus type I. It is somewhat less protective against type II and protects against only 100,000 lethal doses of type III. It contains only 0.035 mg of nitrogen per cubic centimeter. Recently the manufacturers have discontinued the use of pneumococcus type III in the preparation of this solution.

In 1924 Felton⁴ described a method of concentrating and refining antipneumococcic horse serum and has subsequently improved the method. This product represents approximately a tenfold concentration of

the serum with a corresponding increase in its potency. It consists largely of a portion of the globulins. Its nitrogen content is about the same as that of whole serum. This concentrate is marketed in units, a Felton unit being that amount which will protect a mouse against 1,000,000 lethal doses of a virulent culture of pneumococci. As different lots of serum vary considerably in antibody content, it is important to estimate doses in units and not in cubic centimeters. Some

Combined reports of Cecil and Larsen Conner Belk and Sharpe

reports, however, express doses in cubic centimeters. The reason for this is, of course, that the liability to the production of reactions is in proportion to the amount of serum given at one time and not to the unit value.

The results obtained with specific therapy are shown in the tables. These include all the reports in American and foreign literature up to January 1935 that lend themselves to statistical study.⁵ The several series differ somewhat in doses administered, in the method of selecting cases for treatment, and in the method of selecting control groups. They are, however, fairly comparable and demonstrate the value of the method under average conditions. "Serum" as used in the text and the tables indicates concentrated serum. In most instances serum was prepared by Felton's method.

In table 1, pneumococcus antibody solution is seen to be definitely beneficial in type I pneumonia, less so in type II, and of little or no value in type III pneumonia. Surprisingly, it is more effective in group IV than in type I infections. This is due, probably, to a content of

group specific antibodies in addition to its type specific antibodies. The observation is a most important one, particularly since it is demonstrated in all of the three series. This of course has practical importance.

In table 2, antipneumococcus serum is seen to reduce the mortality in type I lobar pneumonia by 40 per cent and to save ten lives per hundred cases. It is of less value in type II but of distinct benefit in types VII and VIII. There is no apparent reason for the rather wide difference in the results of different observers. This series covers a wide range of conditions, some unfavorable, such as the beginning of treatment late in the disease and the inclusion of a number of old patients. The report of Heffron and Anderson is of special interest, as it represents the work of sixty-three practitioners in the state of Massachusetts, under the direction of the department of health and shows that the specific treatment of lobar pneumonia is not a method requiring specially organized hospital services.

When fatalities in the treatment group are considered, it is found that many of these patients were suffering from morbid processes other than the pneumonia. Senility, alcoholism, heart disease and other

complicating conditions were of frequent incidence, and many of the cases were treated late in the disease. Possibly a fairer picture of specific treatment is obtained by the study of its results under more favorable conditions, as shown in table 3.

Table 3 shows an average reduction in mortality of about 50 per cent, with a saving of twenty lives per hundred cases. The 78 per cent reduction in mortality in type II pneumonias, with a saving of fifty lives per hundred cases in the selected series of Cecil and Plummer, is worthy of special mention. This table illustrates the importance of beginning specific treatment as early after the onset of pneumonia as possible.

It also shows the value of this therapy in septicemia, owing to its demonstrated power of sterilizing the blood stream.

In addition to mortality statistics, all observers mention definite clinical benefits in many cases, such as

stream is sometimes sterilized, and extensions of the infection are often prevented. The incidence of complications, however, appears to be about the same in the treated and the untreated patients.

These statistics are based on intravenous serum therapy. The possibility of administering specific antipneumococcus therapy by intramuscular and subcutaneous injections is an attractive one because of the greater ease as compared to the intravenous route. Curphy and Baruch have shown that intramuscular

injections are as effective as the intravenous in rabbits suffering with pneumococcal skin infections.⁶ On the other hand, Rhoades⁷ found that pneumococcus antibodies injected subcutaneously often failed to appear in the circulation. In table 4 are given the results of treatment by these routes.⁸

Table 4 shows that some benefit doubtless results from intramuscular and subcutaneous injections of specific preparations, but this is clearly smaller than after intravenous administration. At present these substitute methods would seem to be justified only when it is impossible to use the intravenous route.

TABLE 5—*Dosage in Specific Antipneumococcus Therapy*

Day of Disease on Which Treatment Is Begun	Concentrated Serum		Units
	Cubic Centimeters of Serum	First 24 Hours	
1-24 hours	5 cc.		90,000
24-48 hours	5 cc.	25 cc.	225,000
48-72 hours	5 cc.	25 cc.	360,000
72 hours	5 cc.	25 cc.	495,000

Give at intervals of two hours
Amounts on subsequent days as indicated clinically
Pneumococcus antibody solution from 50 to 100 cc. three times a day

Table 5 gives a conventional scheme of dosage, that for serum being suggested by Sutliff and Finland.⁹ The first consideration of dosage is to administer serum, or antibody solution, as early in the disease and in as large amounts as is safely possible. Beneficial effects are not experienced until the soluble specific substance in the patient's blood is neutralized by an excess of antibodies. Patients first treated late in the infection, those with septicemia and those with type II pneumonia, require larger doses to effect this result. After the first day's dosage, serum is given either in the same amounts (if no improvement has taken place) or in smaller amounts, until the temperature falls and remains near normal. Armstrong and Johnson¹⁰ feel that if no benefit is observed after seven doses of 20 cc. each (given at intervals of from six to eight hours) it is probably not worth while to continue the administration.

TABLE 6—*Reactions Following Specific Antipneumococcus Therapy*

Reaction	Concentrated Serum	Antibody Solution
Severe allergic	Very rare	None
Mild allergic	5-15%	None
Thermal	10-20%	Frequent to rare
Serum sickness	25-30%	None

make skin and ophthalmic tests, and to refuse serum to those with positive ophthalmic tests and also to those with a history of allergy to horses, the question of reactions appears not to be a serious one. These tests are made with a 1:10 dilution of concentrated serum or better, possibly, with a 1:10 dilution of whole normal horse serum, as the concentrated serum is said to give false positive skin tests. The mild allergic reactions are easily controlled with epinephrine. Only one allergic death is reported. The antibody solution does not cause any allergic reactions and has been given successfully to known allergic individuals.

Reports of specific antipneumococcus therapy in children are few. Nemir observed its effects in both lobar pneumonia and bronchopneumonia produced by pneumococcus types I to XXII inclusive. The mortality in the entire group was reduced from 166 per cent to 98 per cent.

The specific treatment of pneumococcal infections is probably destined to increase in popularity. Serums will doubtless be still further refined, with the result that reactions will be largely eliminated and larger initial doses will be possible. Potent serums for the recently identified types of pneumococci will in all probability soon be available commercially. The demonstrated merit of specific therapy in lobar pneumonia would seem to justify its use in bronchopneumonia and other pneumococcal infections, such as mastoiditis, thus giving it a wider field of usefulness.

Times-Medical Building

ANGINAL SYMPTOMS ASSOCIATED WITH CERTAIN CONSTITUTIONAL DISEASES

C. H. BEACH, MD
RICHMOND, VA

Although angina pectoris has been recognized for nearly two centuries, its pathologic physiology continues to be obscure. Whatever theory is subscribed to, whether the coronary, the aortic or the myocardial, it is generally agreed that the actual attack is precipitated by a demand on the heart which for one reason or another cannot be met.

Keefer and Resnik¹ have proposed on excellent theoretical and factual grounds that anoxemia of the myocardium, however brought about, is the fundamental pathologic condition.

In the past few years I have had occasion to see a number of patients whose presenting complaint was typical angina or attacks indistinguishable from it. Further studies of these cases have revealed various constitutional diseases, the adjustment of which has either improved or done away with the anginal attacks. This relief allows of some interesting speculations on the cause of angina.

In the following case reports data that have not seemed pertinent have been purposely omitted for the sake of brevity.

REPORT OF CASES

CASE 1—A, a man aged 53, admitted to St. Luke's Hospital March 17, 1932, complained of nervousness and discomfort about the heart. About two and one-half years before

admission he became nervous and noticed that his heart was beating very rapidly, and at the same time his wife thought that his eyes appeared more prominent than usual. In spite of an excellent appetite he lost weight. About a year before admission he began to suffer with precordial pain accompanied by shortness of breath, which was brought on by exertion and relieved by rest. There was no edema.

During the next year all the symptoms, including the frequency of precordial discomfort, became more marked. The morning before admission, while dressing, he was seized by a sudden severe pain in the precordial region, which radiated down his left arm. There was extreme shortness of breath and the patient felt that he was in a very precarious condition. A hypodermic of morphine was necessary for relief.

On admission the temperature was 99.6 F, the pulse 140, and the blood pressure 140 systolic, 60 diastolic. The skin was moist and clammy and there was definite exophthalmos. The thyroid was moderately and symmetrically enlarged and there was a fine tremor of the extended fingers. The heart showed an apparent moderate enlargement. The rhythm was very rapid and irregular, strongly suggesting auricular fibrillation. A systolic murmur was heard over the entire precordium, loudest at the apex. The lungs were clear, the liver was not palpable and there was no edema of the feet or ankles. An electrocardiogram confirmed the impression of auricular fibrillation.

A diagnosis of exophthalmic goiter with cardiac enlargement and auricular fibrillation was made. Of course a strong suspicion of angina pectoris was entertained.

During the next several weeks the basal metabolic rate varied from plus 35 to plus 40, and there was considerable general improvement on the preliminary medical management. The cardiac rhythm became regular, with an average pulse rate of 88. April 18, one month after admission, a partial thyroidectomy was done. Recovery was uneventful. He was last seen in July 1933, somewhat more than a year after operation. He had returned to work and was in an excellent general physical condition. There had been no further anginal attacks.

CASE 2—A., a man aged 63, a clerk of the court, seen in the McGuire Clinic, Jan. 14, 1929, complained of numbness of the hands and toes, difficulty in walking, and attacks of precordial pain and oppression brought on by exertion. The present illness dated from about three years before, when he began to have attacks characterized by pain and discomfort in the left side of the chest at times radiating down the left arm, and associated with a feeling of tightness in the chest and shortness of breath. These attacks were brought on by some unusual exertion and relieved by rest. Recently they had become more frequent, and much less exertion was required to precipitate them. During the past six weeks he had noticed numbness and tingling of the hands and toes and difficulty in walking which had grown progressively worse. His hands had become so involved that he could not sign his name legibly.

On examination the temperature was 98 F., the pulse 78, and the blood pressure 150 systolic, 82 diastolic. The gait showed marked spastic ataxia. The skin was somewhat sallow. The hands were slightly edematous and distinctly ataxic. The apex of the heart was normally located and there was a systolic murmur heard at the base. There was a slight sinus arrhythmia. The lungs were clear, the liver was not palpable. Generally increased muscular tonus, anesthesia of the extremities, and loss of vibratory sense were present.

Examination of the blood revealed hemoglobin 75 per cent and red blood cells, 2,820,000, with a color index of 1.3. There was marked macrocytosis with hyperchromia. Poikilocytosis, anisocytosis and polychromatophilia were present. The reticulated count was 11 per cent, leukocytes, 8,000, polymorphonuclear leukocytes, 66 per cent, lymphocytes, 27 per cent, and eosinophils, 5 per cent. The gastric analysis showed an absence of free hydrochloric acid, with a total acidity of 6. The blood Wassermann reaction was negative. The electrocardiogram showed a sinus bradycardia with a rate of 50 but was otherwise normal. The basal metabolic rate was minus 15. Two days later the blood work was repeated with approximately the same results.

A diagnosis of pernicious anemia and coronary disease was made.

From the McGuire Clinic and St. Luke's Hospital.

Read before the Richmond Academy of Medicine Feb. 12, 1933.

¹ Keefer C. S. and Resnik, W. H. Angina Pectoris Syndrome Caused by Anoxemia of Myocardium, Arch. Int. Med. 41: 769 (June) 1933.

The patient was put on a general diet with solution of liver extract-Valentine, 1½ ounces (45 cc) three times a day, and dilute hydrochloric acid, one teaspoonful after meals.

Repeated blood examinations showed a gradual rise in both the hemoglobin and the red blood cell count. April 1, two and one-half months later, they were reported as follows: hemoglobin 84 per cent and red blood cells 5,080,000, with a color index of 0.84.

The patient was followed and the blood frequently checked by the family physician. Shortly after he left the hospital he was put on thyroid, with subsequent repetition of the metabolic rate. He was seen at intervals and heard from by letter. His general improvement was entirely satisfactory. The gait improved considerably and he could write legibly, but he continued to be annoyed by numbness and tingling of the hands and feet.

May 6, the following note was made: "Since medication was begun the patient has had no more anginal attacks nor complained of the precordial discomfort previously described."

The foregoing regimen was continued and no material change in his condition took place during the next five years until March 3, 1934, at which time he was seen at his home suffering from what was thought to be a myocardial infarction. The blood at this time showed a red cell count of 4,000,000. The patient was seriously ill for some time but is now back at his work.

CASE 3—N, a man aged 49, a lawyer coming under observation in February 1925, complained of high blood pressure and sugar in the urine. He had followed a somewhat restricted diet for about one year.

Physical examination was negative except for moderate enlargement of the heart, a systolic murmur heard best at the apex and a marked accentuation of the aortic second sound with a blood pressure of 210 systolic, 100 diastolic. The blood sugar was 265 mg per hundred cubic centimeters. The urine showed a heavy trace of sugar and a trace of albumin. The electrocardiogram was normal.

A diagnosis of diabetes mellitus, arteriosclerosis and hypertension was made.

He was put on a restricted carbohydrate diet and got along well until April 1925, when he began to complain of trouble with his right eye. Examination showed a hemorrhagic retinitis of moderate intensity on the right.

A more careful control of the diabetes was advised and carried out. Small doses of insulin were given. In this manner his condition remained satisfactory until May 1933 when he began to notice a sensation of substernal constriction and discomfort on walking, which would subside when he stopped to rest. There was no real pain. Thorough examination including an electrocardiogram, showed nothing new of significance. He was given aminophylline, one tablet three times a day.

During the next eighteen months, until September 1934 there was no particular change in his condition except that he was having attacks of typical anginal pain brought on by exertion and relieved by rest. The electrocardiogram was again normal, the blood pressure was 204 systolic, 94 diastolic, the pulse 56, and the urinalysis negative.

During the next several months the anginal attacks became more frequent and more severe, and less exertion was required to precipitate them. One unusually severe attack was relieved by glyceryl trinitrate. December 17 the blood sugar was 100 at noon. He was taking 7 units of insulin in the morning and 7 units at night. He was asked to omit the morning dose. Jan. 25, 1935, five weeks later, the blood sugar was 200 at 11:15 p. m. There had been no more of the severe anginal attacks and in fact practically no discomfort about the cardiac region.

CASE 4—Mrs. R, aged 62, a housewife, seen in November 1928, complained of nervous prostration, extreme exhaustion and precordial discomfort.

The present illness dated from the latter part of 1927, at which time she began to complain of a feeling of oppression in the chest. The family physician suspected angina pectoris and advised her to keep glyceryl trinitrate always at hand. Shortly after that she suffered a paroxysm of excruciating pain in the precordial region following exposure to severe cold. This pain was relieved by glyceryl trinitrate. During the next

year or so she had several similar attacks, which were much more frequent during the cold weather and definitely associated in her mind with exposure to cold.

In November 1928, when the cold weather began, her attacks became more frequent and more severe and a trip to Florida was recommended by her physician in New York. On her arrival in Richmond the pain was so severe that it was necessary for her to stop at a hotel. Attacks were occurring from eight to ten times a day and were only partially relieved by glyceryl trinitrate. She was brought to St. Luke's Hospital in December.

She was well developed and well nourished and in no particular distress. She appeared to be generally sluggish and mentally dull. The skin was dry. The most striking difficulty was her inability to keep warm and her great fear of becoming chilled. The heart was normal except for a systolic murmur heard over the base. The pulse rate was 80 and the blood pressure 124 systolic, 76 diastolic. The electrocardiogram showed a right axis deviation, negative T waves in lead I, and iso-electric T waves in leads 2 and 3. The P wave was absent in lead I and the QRS complexes in all three leads were somewhat slurred but not widened.

During the next three weeks in the hospital she had many severe attacks of precordial pain, occasionally requiring as many as twenty-one ½₁₀₀ grain (0.0006 Gm.) tablets of glyceryl trinitrate in twenty-four hours. In addition, she was receiving aminophylline and opiates as needed.

Owing to the failure of the customary procedures for the relief of angina and the patient's general appearance of hypothyroidism or myxedema it was decided to try the administration of thyroid. A basal metabolic rate was not done because of her critical condition. The thyroid medication was begun on Jan. 24, 1929, with 2 grains (0.13 Gm., Burroughs, Wellcome & Co.) three times a day. During the next week there was remarkable clinical improvement. The attacks had practically disappeared and for the first time she allowed the cover to be removed from her neck and arms.

The patient left the hospital February 12, remaining on the same dose of thyroid. The clinical improvement continued and she remained free from precordial discomfort. For several months the basal metabolic rate ranged between minus 4 and minus 10. The electrocardiogram returned to normal. For several years she was kept on the thyroid and suffered only an occasional attack, except on one occasion when the metabolism fell to minus 20 and there were several paroxysms of pain following exposure to cold. The patient has not been heard from for the past two years.

COMMENT

Patient 1 had suffered from exophthalmic goiter for two and one-half years. On admission to the hospital the pulse rate was 140, and it is well known that when the heart rate is greatly accelerated a marked shortening of the diastolic phase occurs. When this acceleration exists over a long period the minute volume of coronary flow is greatly decreased. In this case the heart was continuously urged on by excessive stimulation of the thyroid, and the myocardium was forced to do a greater amount of work. Therefore it is reasonable to believe that under these conditions there was not only a relative anoxemia but also a relative deficiency of fuel to supply the energy requirements of the laboring heart. Since this explanation conforms to the coronary theory in that the coronary flow was reduced, it does not seem necessary to postulate a sclerotic process or spasm to explain the pain. This case of classic exophthalmic goiter was accompanied by typical anginal attacks, which disappeared following the patient's recovery from hyperthyroidism.

In case 2 there was probably a deficiency in available oxygen due to a lowering of the normal qualitative state of the blood. The lowered oxygen supply to the myocardium was adequate to meet the demands on the heart during rest and restricted activities but inadequate

when conditions that imposed an extra load were added. In this case the anginal symptoms ceased after the blood returned to its normal state.

There are in the literature several reported cases in which hypoglycemia or insulin shock brought about typical severe anginal seizures in patients suffering from coronary disease, also deaths in which insulin shock has been the precipitating factor in patients suffering from cardiac decompensation. Middleton and Oatway,² in their studies of insulin shock and the myocardium, stress the importance of carbohydrates in all muscular activity. Evans³ calculated that the normal heart obtained one third of its energy from the oxidation of carbohydrates. They show that during hypoglycemia there are certain definite changes noted on the electrocardiogram in regard to the T waves which show the inversion usually thought to be associated with coronary disease. Some showed changes in the P waves, and slurring of the QRS complexes was also noted. In case 3 an increase in the blood sugar level brought about marked clinical improvement, theoretically by supplying the myocardium with a greater amount of dextrose and thereby an increase in available energy. It seems rational, therefore, that keeping the blood sugar level somewhat above normal limits in elderly diabetic patients subject to anginal pain is well worth a trial.

In case 4 the rate of conversion of food to energy by oxidation was probably markedly reduced. It is also likely that there was an underlying pathologic process of the coronary arteries and in the presence of this condition, the slowed up oxidative rate imposed a very real energy deficit on the myocardium. On thyroid medication this patient showed remarkable clinical improvement, which continued.

CONCLUSIONS

1 A somewhat broader concept than anoxemia as the cause of anginal pain is suggested, namely, that the paroxysms occur when the available energy is not equal to the demands made on the myocardium.

2 It would appear that this energy deficit may be brought about by many different causes, for example

(a) Reduced coronary flow or "ischemia," whether due to organic narrowing, spasm or shortening of the diastolic phase over a prolonged period.

(b) A relative oxygen deficiency alone as in anemias.

(c) A relative deficiency in available fuel, as in hypoglycemia.

(d) An abnormally slow rate of oxidation of fuel to form energy, as in myxedema.

3 With this broader concept in mind it behooves one to scrutinize each patient presenting anginal symptoms with the utmost care in an effort to uncover and correct any underlying constitutional condition which alone or in combination with reduced coronary flow might precipitate attacks.

Clinical Notes, Suggestions and New Instruments

EPIDERMOID CYST COMPRESSING THE VERMIS OF THE CEREBELLUM

LEO M. DAVIDOFF, M.D., NEW YORK, AND H. T. VON DEESTEN, JERSEY CITY, N. J.

Lereboullet¹ in a monograph on the tumors of the fourth ventricle reviews all the cases of dermoid and epidermoid tumors and cysts in the posterior fossa that he has been able to find reported in the literature. According to him, only nine dermoid and eight epidermoid cysts of the posterior fossa have been recorded. Of these, only one of each has been reported as operated on successfully: a dermoid cyst overlying the vermis of the cerebellum, reported by Brock and Klenke² (operated on by Elsberg), and an epidermoid tumor, reported by Van Bogaert and Martin³ (operated on by Cushing).

In view of the rarity of these tumors, their greater rarity in this location, and the extremely rare cure of the condition by surgery, the following successful surgical case is reported.

REPORT OF CASE

History—J. J. L., a man aged 42, a lawyer, admitted Nov. 5, 1934, complained of noise in the top of the head, an unsteady gait and vomiting.

About three or four years before the patient began to experience a loud roaring noise in the head "like Niagara Falls," which occurred intermittently and lasted from a few minutes to several hours.

About two years before, he first noticed unsteadiness of gait due not to weakness of the legs but to a loss of equilibrium and an inability to keep his direction. This progressed to the point at which he required support when walking, and a friend was devoting himself to serve as his prop.

For about six months he vomited frequently. This occurred without nausea or any other warning. It was projectile and did not seem to be related to the taking of food. Occasionally he had severe headaches, especially when reading, and his eyesight he believed, was becoming impaired.

Examination—The patient was large and showed evidence of recent loss of weight. He was intelligent and cooperative. He walked unsteadily with a broad base, swayed in the Romberg position and was unable to stand on either foot alone without falling. All coordination tests were poorly done because of ataxia, asynergia and tremor of the upper as well as the lower extremities. The voice was a little monotonous and quavering but test phrases were delivered without any difficulty.

The deep and superficial reflexes were normal, no abnormal reflexes were demonstrable. Muscle strength was good throughout and no local weaknesses were demonstrable. Sensation was normal throughout. The cranial nerves were normal except for some atrophy of the optic disks and slight blurring of their margins. The pupils reacted somewhat sluggishly to light.

Routine blood counts, urinalysis, and blood and spinal fluid Wassermann tests were all negative.

Plain roentgenograms of the skull showed a definite atrophy of the posterior clinoid processes indicating an increase in intracranial pressure. In the right cerebellar lobe a small fleck of calcification about 6 by 2 mm was present. These observations strongly suggested a right cerebellar tumor.

Ventriculograms showed a symmetrical dilatation of the ventricular system, including the two lateral and the third ventricles and the aqueduct of Sylvius. The fourth ventricle appeared somewhat flattened in the region of the festigium thus confirming the diagnosis of cerebellar tumor (C. G. Dyke).

Operation—The operation was done, November 12, by one of us (L. M. D.) under local anesthesia, the region of the cerebellum being exposed by the usual suboccipital approach.

² Brock S. and Klenke, D. A. A Case of Dermoid Overlying the Cerebellar Vermis. *Bull. Neurol. Inst. New York* 1: 328 (June) 1931.

³ Van Bogaert L. and Martin P. Les tumeurs du quatrième ventricule et le syndrome cérébelleux de la ligne médiane. *Rev. Neurol.* 2: 431 (Sept.) 1924.

The dura was under considerable tension, and the lateral ventricles had to be emptied before this membrane was opened. As soon as the dura was opened, a very large cyst was exposed, occupying the position of the vermis of the cerebellum. The cyst wall was thin and of a dark opalescent opaque appearance. This wall was punctured and a copious flow of thick yellowish brown, opaque, viscid, oily fluid resulted. This fluid, when examined under the microscope, contained amorphous debris and numerous cholesterol crystals. Together with this fluid, large solid amorphous masses of brown material were removed. The cyst was attached to the cerebellum at only one place deep in the right hemisphere. The thin pedicle, which contained calcium (accounting for the shadow in the roentgenogram), was amputated with sufficient normal tissue to assure its complete eradication.

Pathologic Report (Wolf)—The tissue consisted of masses of homogeneous pink-staining substance, on the margins of which were strips of epithelial membrane attached to narrow bands of glial tissue. The epithelium was composed of two or three layers of cells. The basal layer was made up of large-bodied cuboidal cells with prominent dark-staining nuclei. The other cells were polygonal or somewhat flattened and markedly vacuolated, and their nuclei lay within the large vacuoles.

The diagnosis was epidermoid cyst.

Course—The patient made an uneventful recovery and was discharged much improved two weeks after the operation. When seen two months later, he was practically free from his preoperative symptoms.

COMMENT

Clinically this case presented a slowly progressive syndrome of an expanding lesion in the posterior fossa, similar to other reported cases of epidermoid cysts of the cerebellum, all of which occurred in adults and all showed a slowly progressive course of at least two years' duration. There is nothing in the clinical picture to indicate specifically the nature of the lesion beyond the evidence that the lesion is a tumor located in the posterior fossa growing slowly and therefore probably benign in character. The frequent occurrence of calcium deposits in these tumors is of aid in their localization by the x-rays. But since calcification may also occur in ependymomas, astrocytomas, hemangioblastomas and perhaps other tumors occurring in the posterior fossa, this finding in the roentgenogram is again of no aid in the diagnosis of the specific character of the tumor.

Morphologically, the tumor in our case was unusual in that it was largely cystic. As a rule the epidermoids are solid tumors and the dermoids are frequently cystic. Because of its cystic character a careful search for dermal elements such as hair, hair follicles and sebaceous cysts was made, but none were found.

For a long time the nature of these congenital tumors was not wholly understood. Cruveilhier,⁴ who was the first to describe them, called them "pearly tumors" because of the glistening appearance of the capsules in the cases that came into his hands. Johannes Müller⁵ in 1838 was able to demonstrate cholesterol crystals in the debris occurring within these growths and gave them the name "cholesteatoma," by which they are frequently known even today. Neither characteristic on which these two names are based is essential to the diagnosis. Any tumor, congenital in origin, whether glistening or not, whether it contains cholesterol or not, which consists of the ectodermal component of the skin, belongs to this group, properly called "epidermoids." The dermoids are distinguished by their origin from both the ectodermal and the mesodermal components of the skin. They frequently contain hair and functioning sebaceous cysts and are thus often cystic.

SUMMARY

Epidermoid tumors occurring in the posterior cranial fossa are extremely rare lesions.

A case of epidermoid cyst in this location was successfully treated by operation.

INTRA ABDOMINAL APOPLEXY

J. R. BUCHBINDER, M.D., AND EARLE I. GREENE, M.D., CHICAGO

Whereas rupture of a cerebral vessel due to arteriosclerosis is not an unusual accident, the spontaneous rupture of vessels elsewhere in the body is comparatively rare. A review of the literature reveals reports of rupture of vessels of the extremities, renal artery, cystic artery and hepatic artery, but in these cases the rupture was usually secondary to an inflammatory process. According to Fishberg,¹ "arteriosclerosis of the large arteries, in essential hypertension, is present in the vast majority of cases, often in widespread form, especially if there is an associated diabetes. In the aorta and its branches there are generally well marked or severe arteriosclerotic changes, but the vessels show little more atheromatous changes than are usual at the age of the patient."

The spontaneous rupture of an arteriosclerotic vessel into the abdominal cavity is extremely uncommon, having previously been encountered three times.² In Starcke's case a rupture of the gastroduodenal artery occurred. Budde found that one of the branches of the left gastro-epiploic had ruptured. A sclerotic branch of the left gastric artery was found to have

Hematoma into gastrohepatic omentum

ruptured by Green and Powers. Two other cases³ closely simulated this condition but are not included. In the former, no bleeding vessel was found; in the latter, the rupture occurred during labor, which should classify it among the traumatic cases.

All the cases reported have one noteworthy feature in common. Without exception, the point of rupture was found to be a vessel arising from the coeliac axis. Why this should take place is not understood.

Hypertension was another characteristic finding in all but one case. In Starcke's case, a man aged 60, a definite history of hypertension, with sclerotic vessels, an enlarged heart and an increase in blood pressure was obtained. The case described by Green and Powers gave a definite history of hypertension with indication of marked arteriosclerosis. In Budde's case, however, there is no mention made of vessel changes or increase in blood pressure. His patient was 27 years old and

From the Department of Surgery, Northwestern University Medical School, and the Cook County Hospital.

it is permissible, perhaps, to feel that changes in the vessels had not yet occurred. Starcke's patient was 60 years old, Green and Powers' patient was 54, our patient was 57.

REPORT OF CASE

B G, a man, aged 57, admitted to the Cook County Hospital, complained of severe abdominal pain of five hour's duration. Shortly after eating a heavy meal he suddenly experienced an agonizing knifelike pain in the upper part of the abdomen which doubled him up. Nausea and vomiting followed. After thirty minutes the pain subsided somewhat, becoming diffuse, with radiation to both shoulders. A physician was called, who advised immediate hospitalization.

On admittance to the surgical ward it was evident that the man was acutely ill. Both legs were acutely flexed and the skin was cold and clammy. A cold sweat covered the entire body. The abdomen was boardlike, with tenderness over the entire abdomen, especially in the region immediately above the umbilicus. Liver dullness was not obliterated. There was evidence of shifting dullness in the flanks. The temperature was below normal, the blood pressure was 115 systolic 80 diastolic respirations ranged between 30 and 40 per minute, and the pulse was 95 per minute. There was moderate cyanosis with some evidence of air hunger. The blood showed 3,400,000 red cells with 8,500 white cells. The urine contained a trace of albumin, a few hyaline casts and a few pus cells but was negative for blood or sugar. The patient was exceedingly thirsty, constantly moving about, and as we watched him there was definite evidence that his condition was growing more precarious.

A diagnosis of acute pancreatitis was entertained but held in abeyance because of the blood pressure of 115 systolic and 80 diastolic. The question of a perforated peptic ulcer was considered, but the presence of liver dullness made us hesitate, even though we were aware that this finding was at times absent. On the way to the operating room fluoroscopy was done but no intra-abdominal air bubble was visible. The possibility of an acute coronary disease held a prominent part in our minds, and it was not without considerable trepidation that the man was placed on the operating table. The immediate preoperative diagnosis was an acute pancreatitis.

When the abdomen was opened a considerable quantity of bloody fluid escaped. Fat necrosis was not evident. A large purplish swelling was found in the gastrohepatic omentum. When the anterior layer was opened a large blood clot was evacuated and an actively bleeding sclerotic vessel was seen and identified as the right gastric artery. The perforation had occurred immediately above the level of the pylorus. The vessel was doubly ligated, and as the man's condition was not too good the abdomen was hurriedly closed after evident clots had been removed. Unfortunately no portion of the vessel was taken for future study.

Saline and dextrose solutions were given intravenously and under the skin. A smooth postoperative period followed. Subsequent questioning revealed the fact that for a period of several years he had complained of dizziness and headaches. A year or so previously he had seen a physician who informed him that he had a very high blood pressure. Ten days after the operation his blood pressure was 190 systolic, 115 diastolic. The patient was asked to return but to date we have not seen him.

It is interesting to note that in all previously reported cases the preoperative diagnosis was either an acute pancreatitis or ruptured peptic ulcer. In every case the onset was exceedingly dramatic, characterized by sharp agonizing pain in the epigastrium with boardlike rigidity followed by manifestations of collapse. In our case the radiation of the pain to both shoulders not unlike that occurring in ruptured ectopic pregnancy might have offered a clue, but the diagnosis of an apoplexy of an intra-abdominal vessel was not thought of.

SUMMARY

The fourth case of a true intra-abdominal apoplexy on an arteriosclerotic basis is reported. In previous reports ruptured vessels were the gastroduodenal, left gastro-epiploic, left gastric and in our case the right gastric. All are branches of the celiac axis. With one exception all the cases occurred in

patients with hypertension. The onset in all cases was acute, followed by evidence of collapse. A correct preoperative diagnosis is yet to be made. In each instance a diagnosis of acute pancreatitis or ruptured peptic ulcer was made. Operation was done in the four cases, the bleeding vessel being found and ligated, with recovery in each instance.

DUODENAL ULCER WITH RUPTURE ON THE FOURTH DAY OF LIFE

FRANK SEINSHEIMER, MD CINCINNATI

Duodenal ulcer in infants is not a rare condition. Perforation, however, of duodenal ulcer under one year has been reported only occasionally. A review of the literature reveals reports of twelve such cases since 1868.¹

The following is the report of a case of perforated duodenal ulcer occurring on the fourth day of life.

Delivery of baby boy L by Dr F A S Kautz was by cesarean section in the eighth month of pregnancy, the mother having had a hemorrhage from a placenta praevia centralis. The birth weight was 6 pounds 12 ounces (3,062 Gm). The baby appeared normal after birth, with the exception of an inguinal hernia on the left side. Breast feeding was not instituted because of the mother's condition, but the infant received 1½ ounces (45 cc) of diluted dried milk every three hours. There was persistent forceful regurgitation of the feedings. On the third day, diluted dried skim milk was given. Each feeding was preceded by atropine. On the fourth day of life there was decided icterus, and clinically dehydration was observed. On this day symptoms of shock suddenly developed and shortly afterward the abdomen became distended, and in a few hours the scrotum became edematous and discolored. There were several areas of reddish discoloration on the lower part of the abdomen. The temperature was subnormal, respiration rapid and shallow, and the pulse rapid and feeble. Physical signs of fluid developed in the abdomen, and the diagnosis was made of a ruptured hollow viscus. A transfusion was given, but the baby died shortly thereafter, before surgical intervention could be attempted.

Necropsy was done by Dr Mortimer Herzberg. When the peritoneal cavity was opened the entire peritoneal cavity and the intestine, which was collapsed, were covered over with a creamy yellow foamy fluid. The peritoneum was intensely congested and somewhat glistening. The suspensory ligament and umbilical vein were persistent and congested. The urachus was not unduly prominent. The right obliterated hypogastric vein was congested. When pressure was made over the left scrotum, thick yellowish creamy material exuded from the internal inguinal ring, which was apparently open. No similar fluid exuded from the right inguinal ring, which was apparently more firmly closed than its fellow. The retroperitoneal tissues were intensely congested and contained numerous small gas bubbles. The appendix was apparently normal except for slight congestion and pointed retroceally. There was slight dilatation or pouching of the cecum in the region of the ilioretrocecal valve. The intestinal coils, except as noted, were moderately congested but collapsed.

There was considerable dilatation of the second portion of the duodenum, and when this portion was opened a small perforating ulcer was found. The perforation was surrounded by a small circumscribed reddened area, which was not indurated. The stomach was contracted and there was a hemorrhagic necrotic area, especially in the greater curvature. When the stomach was opened the mucosa was congested and in this area the wall was markedly thin.

Below the duodenal perforation, the intestine contained a small amount of thick pasty, yellowish material. The small intestine was congested. There was no evidence of other ulcerations. The large bowel presented no evidence of ulceration.

Microscopic examination of the tissue adjacent to the perforation in the duodenum showed no cellular evidence of inflammation.

ENDOCARDITIS DUE TO THE HEMOLYTIC PARA- INFLUENZA BACILLUS

WAYNE W. FOX, M.D., ROCHESTER, N. Y.

Endocarditis due to the hemolytic hemophilic bacillus is uncommon. Four cases have been reported: the first in 1923 by Miller and Branch,¹ two in 1932 by Fothergill, Sweet and Hubbard² and one in 1933 by De Santo and White.³ In 1922 Rivers⁴ showed that influenza bacilli are not all identical in their growth requirements. Those which are not strictly hemoglobinophilic he placed in the para-influenza group. In the classification suggested by Valentine and Rivers⁵ in 1927 the hemophilic group is composed of the hemolytic and the non-hemolytic influenza bacillus, the hemolytic and the nonhemolytic para-influenza bacillus and *Bacillus haemoglobinophilus-canis*. In 1928 Russell and Fildes⁶ reported a case of endocarditis associated with a nonhemolytic para-influenza bacillus. The following is a report of a case of endocarditis associated with the hemolytic para-influenza bacillus.

REPORT OF CASE

History—Mrs. F. C., aged 40, white, a housewife, had scarlet fever complicated by multiple abscesses on the lower extremities seven years before admission. Five years before admission, after an operation for an ectopic pregnancy, the patient was told that she had "heart trouble." After that she gained over 50 pounds (23 Kg.) and for two years noted dyspnea on moderate exertion. There was no history of rheumatic fever or chorea.

The present illness began with general malaise seventeen days before admission. This lasted for three days and was followed by abdominal cramps, diarrhea, vomiting, sore throat and fever. She stayed in bed for three days, after which she felt somewhat improved. On the fourth day, however, she had a severe shaking chill followed by high fever. This recurred from two to five times a day thereafter. During the week preceding admission she noted pain in the finger tips and small red spots on the left wrist. On the day of admission she complained of a feeling of precordial oppression, which lasted about an hour. The colic, diarrhea, vomiting and headache had continued with only slight abatement up to the time of admission.

At almost the same time that the patient became ill, there were five other people in the immediate neighborhood, three of them in her own family, who complained of a similar illness. All had mild prodromal symptoms followed by an acute gastrointestinal upset lasting three or four days and accompanied by fever, backache, headache and prostration. One of the group, a child aged 6 years, had three generalized convulsions. Cultures of the stools of this patient were reported as negative for typhoid and dysentery organisms. All five persons still felt

exhausted three weeks afterward. The patient was the only one of those taken ill who did not recover from the acute symptoms in from three days to two weeks. The source of the infection was considered to be the 6 year old child who was the first to become ill.

Examination—On admission the patient's temperature was 39 C (102.2 F), pulse 88 and respirations 22. She appeared to be acutely ill and slightly disoriented. The face was flushed and bathed in sweat. One fresh petechia was noted on the conjunctiva of the left eye and another on the buccal mucosa. Fading petechiae were observed over the inner aspect of the left wrist and over the upper abdomen. The fundus of each eye showed narrow arterioles and arteriovenous notching. The nose and throat were red and dry. The lungs were clear. The heart was not accurately outlined, owing to the large breast and to the hypersthenic chest conformation. The apex impulse was not felt. The sounds were muffled but of fair muscular quality. The first sound at the apex was somewhat snapping and the second sound was more accentuated at the pulmonic than at the aortic area. The rhythm was regular except for an occasional extrasystole. There was a systolic murmur audible over the entire precordium, which was loudest and blowing in quality at the apex. The blood pressure was 180 systolic, 120 diastolic. The spleen extended 6 cm. below the costal margin in the left anterior axillary line. It was firm and tender. The remainder of the examination revealed no abnormalities.

The leukocyte count was 15,000, with 90 per cent polymorphonuclears. The hemoglobin was 148 Gm. per hundred cubic centimeters (Sahli). The Wassermann and Kahn tests were negative. The urine showed a trace of albumin and a few casts. Culture of the urine was sterile. Stools were liquid and fetid and contained small bits of mucus but no gross or occult blood. Cultures of the stools revealed no typhoid, paratyphoid-dysentery organisms. Blood cultures made on the second, fourth, seventh and fourteenth days all yielded pure growths of the hemolytic para-influenza bacillus.

Course—The course of the disease observed in the hospital was marked by shaking chills, profuse sweats and a septic temperature. On the third day petechiae were noted on the eyelids, in the retinas and on the hard palate. On the seventh day a nonproductive cough developed. Rales were heard at the base of the left lung and in the right interscapular area. These signs were observed inconstantly thereafter. On the seventeenth day left hemiplegia developed and the patient became comatose. The neck was somewhat stiff, the pupils were fixed and the optic disks were hazy in outline. Lumbar puncture yielded a clear spinal fluid with normal pressure, 3 cells per cubic millimeter and no increase in protein. No organisms were found in smear or culture. The Wassermann reaction and colloidal gold tests were negative. The patient died thirty-six hours after the onset of hemiplegia.

Treatment had consisted of six blood transfusions of 250 cc each given two or three days apart.

The clinical diagnosis was (1) subacute bacterial endocarditis, (2) hemiplegia due to an embolism in the right cerebral hemisphere, (3) bronchopneumonia, (4) rheumatic heart disease with mitral stenosis and insufficiency, and (5) hypertension.

Postmortem Examination—A complete autopsy was performed twelve hours after death. The significant pathologic conditions were found in the cardiovascular system, lungs, spleen and kidneys. The heart weighed 500 Gm. The aortic valve was normal with the exception of several small nodular vegetations at the valve margin. The mitral valve measured only 7 cm. in circumference and was deformed by fibrous thickening of the leaflets and of the chordae tendineae. Superimposed on this old process was a large pendulous vegetation attached to the right border of the anterior leaflet and fused with the right border of the posterior leaflet. The surface of the vegetation was granular and yellowish pink. The lungs showed congestion and a few small areas of bronchopneumonia. Several of the arterioles of the lungs were occluded by organizing thrombi. The spleen weighed 730 Gm. and was typical of acute splenic tumor with a few areas of organized and organizing infarction. Each kidney showed several small infarcts and evidence of an acute glomerulitis. The right kidney weighed

140 Gm and the left 240 Gm. The right renal artery was almost completely occluded by an antemortem thrombus, which was attached near its orifice and projected slightly into the lumen of the aorta. Just above the bifurcation of the internal carotid artery there was an antemortem thrombus about 6 cm long, which completely occluded the vessel. The right cerebral hemisphere was slightly softer than the left. The meninges were clear.

Bacteriologic Examination—Postmortem cultures of the heart blood, lungs and spleen did not yield the hemophilic bacillus, but microscopic sections and smears made from the crushed vegetation showed gram-negative bacilli the morphology of which was identical with that of the organisms isolated from the antemortem cultures.

The identity of the organism was established by its morphology, its growth characteristics and a study of its growth requirements. In stained smears the organism always was gram negative. It appeared most frequently as a short rod with quite marked bipolar staining, with numerous coccobacillary forms. After growth on artificial culture mediums for several weeks it tended to form filaments like those of the true influenza bacillus. Growth in blood broth was always diffuse, producing complete hemolysis in seventy-two hours. The characteristic colonies on rabbit blood agar plates after forty-eight hours of growth were about 1 mm in diameter, discrete, raised, translucent and smooth. Each possessed a small elevated peak in the center. Around the colony was a definite zone of beta hemolysis. The growth requirements of the organism were determined according to the method of Rivers. The two accessory growth factors, X (heat stable) and V (heat labile), were prepared from laked rabbit red corpuscles. The factor V was prepared from fresh brewers' yeast. With plain peptone water as a base, sets of tubes were inoculated which contained plain peptone, peptone plus X, peptone plus V, and peptone plus X and V. Transfers were made every twenty-four hours with a wire loop that delivered approximately 0.02 cc, and each tube that showed growth was checked by streaking to the surface of a rabbit blood agar plate. The original inoculum was a twenty-four hour culture in Douglas broth enriched with rabbit blood. In peptone water and in peptone water plus X, growth occurred through from three to five transfers. In peptone plus V and in peptone plus X and V, growth occurred with undiminished vigor through twelve transfers. According to the classification of Valentine and Rivers, therefore, the organism isolated in this case was a hemolytic para-influenza bacillus.

The agglutination reactions of the organism are of interest but apparently were of no specific significance in this infection, according to the following data. The serums of the patient and of two members of her family agglutinated the organism in a dilution of 1:320. However, the serums of eight normal controls also agglutinated the organism in titers of from 1:80 to 1:320.

The organism also proved to be nonpathogenic in the laboratory animals that were inoculated. In each injection 1 cc. of a forty-eight hour broth culture was used. Intraperitoneally it was harmless to mice and guinea-pigs. Intravenously, intrathoracally and by the intracardiac route it was harmless to rabbits. Cultures taken from the site of injection, the heart blood and the spleen were all negative when the animals were killed three weeks after the injections. No pathologic changes were observed in the organs of any of the animals except the one that received the injection into the heart. A well healed scar marked the passage of the needle into the left ventricle and apparently through it into the right ventricle. On the right side of the intraventricular septum at the site of the puncture wound of the injection, was a very small pink nodule slightly rough on its surface. The remainder of the endocardium and the valves were normal, however and the other organs, notably the lungs and spleen were entirely normal.

The case here reported is interesting not only because of the unusual organism isolated but also because no portal of entry to the blood stream could be found. This was true also of the cases of hemolytic hemophilic endocarditis previously reported. Perhaps the similarity of the early symptoms manifest in this patient and in the five other persons who were taken ill almost simultaneously is noteworthy.

ADVANCES IN THERAPEUTIC TECHNIC

CLINICAL LECTURE AT ATLANTIC CITY SESSION

BERNARD FANTUS, M.D.
CHICAGO

It requires temerity to discuss advances in therapeutics before the most advanced group of physicians in the whole of North America. In possible justification of this paper I plead my special interest in therapeutic technology, my hope of provoking constructive criticism and my conviction that—even in these days of the airplane, telegram and radio—there still exists too great a lapse of time between the announcement of a valuable idea and its acceptance by the rank and file of the medical profession.

DRESSINGS

For instance, consider as simple a matter as dressings. Is it not a highly rational principle that clean wounds need no absorbent dressing since there is nothing to be absorbed? And yet everywhere dry absorbent dressings are still being piled inch high on clean operative wounds in spite of the fact that B. J. Golden¹ described in January 1934 a copper gauze dressing that should be superior to the conventional absorbent dressing from every point of view, including that of economy. Absorbent dressings are not only useless but even detrimental to the healing of granulating wounds after infection has been eradicated. Infected wounds need moist absorbent dressings that favor drainage. As soon as the infection has been overcome, however, such dressings do harm. Just as they would in the eye or nose, absorbent dressings produce a foreign body irritation on any raw surface, draining away a great deal of reparative material. Moist dressings also delay healing by macerating the advancing edge of epithelial growth and preventing its maturation. Dry dressings stick to the surface, with all the well known disadvantages resulting therefrom. In August 1934 John E. Cannaday² described a wire screen dressing for granulating wounds that permits exposure of the surface to air and light, thus hastening healing while saving a great deal of time and dressings, and still the fresh air treatment of sores is being sorely neglected.

The modern zinc oxide adhesive plaster is now so well borne by the average human skin that the plaster may remain in place for weeks. Hence the washable adhesive plaster that is now available should supersede the old variety without a water-proof backing. Also there is no reason why adhesive plaster should not be made the color of the skin so as to render it less conspicuous on exposed surfaces. There is also no reason why the therapeutic maxim should not be more generally followed that any pain aggravated by or produced by motion should be mitigated or checked by limiting that movement or making it impossible.

Elastic adhesive plaster has been on the market for some time and still it is not employed as extensively as it should be. When mere retention of a dressing is necessary, elastic adhesive plaster generally should be

Read before the General Scientific Meeting at the Eighty-Sixth Annual Session of the American Medical Association, Atlantic City, June 11, 1935.

² Cannaday, J. E. Discussion of Some of the Methods Used in Treatment of Superficial Granulating Wounds. *Am. J. Surg.* 25: 288 (Aug.) 1934.

preferred to the nonelastic kind because it is more comfortable. Elastic adhesive plaster finds perhaps its best application in the treatment of a varicose ulcer, especially when combined with the rubber sponge dressing, as suggested by A. Dickson Wright.³ The treatment of bedsores also will probably be revolutionized by providing in this manner a soft "false bottom" for the patient to lie on, as indicated by T. J. A. Carty.⁴ The pain of hepatic congestion may be minimized by subcostal strapping with elastic adhesive plaster,⁵ a strapping that might also be useful in certain stages of cholecystitis by tending to maintain a relative degree of rest. A tight abdominal binder has also been advocated⁶ in the therapy of pulmonary emphysema so as to antagonize, as far as may be, the deficiency in expiratory collapse of the lung.

Nonadhesive elastic bandages might with advantage replace rubber bandages for varicosities of the legs. They are much cheaper than elastic stockings, they always fit, they are washable and they are now made in such an attractive color (pink) and material (silk) as to suit the most fastidious. While in most instances the injection treatment of varicose veins has made the tolerating of varices an almost inexcusable neglect, there are some cases in which that type of treatment cannot be employed. For these the elastic bandage support is still of great importance, as it is also when a tendency to recurrence manifests itself after injection or surgical treatment. These bandages should find their greatest use in the prophylaxis of varicosities during pregnancy, for which purpose they should be employed as a routine measure.

MEDICATION OF MUCOUS MEMBRANES

Particularly slow is progress in those fields of medicine that require the cooperation of the prescribing physician and the dispensing pharmacist. This is well illustrated by the packaging of salves in collapsible tubes, which is still completely in the hands of manufacturers of pharmaceutical specialties, while the prescription pharmacist is in this as well as in many other respects woefully behind the times. Artists' oil paints have long been put up in tubes, tooth pastes and all kinds of toilet preparations are put up in tubes, but the doctors' salves are still dispensed in the old-fashioned salve pot, in spite of the fact that tubes are cheaper, cleaner and more economical. However, a great obstacle to the introduction of collapsible tubes in general prescription practice is the fact that these tubes are marketed only in gross lots. This would not continue to be true if the demand justified the manufacturer's putting them up in cartons of a dozen. The creating of such a demand is entirely in the hands of the prescribing physician.

The special reason physicians should be interested in collapsible tubes is that there is need of them for the medication of mucous membranes by salves and jellies, the discriminating use of which might well revolutionize the therapy of the accessible mucosae. Medication of the mucous membranes, I believe, still awaits its Unna to devise more efficient forms of administration than the too briefly acting lotions and sprays that are

employed almost exclusively at present. Salves may be produced that cling to the mucosa—they might be aqueous jellies or emulsions of butter-like consistency—and these emulsions might be either of the oil in water or the water-in-oil variety. By appropriate medication of either the watery or the oily phase of either kind of emulsion, it might be possible to secure a great variety of effects in gradations of intensity and duration of action.

Until collapsible tubes with tips suitable for rectal application are more generally available, the suppository will remain the most important type of rectal administration. It is discouraging to think that as long ago as 1920 Gilbert⁷ suggested the proper method of inserting suppositories—large end first, and that European manufacturing pharmacists produced suppositories suitable for that method of insertion about twenty-four years ago, but that as yet in this country, which is supposed to be progressive, there are but few pharmacists acquainted with the new shape. Like the automobile, the modern suppository should be streamlined, its blunt end rounded. Once the greatest circumference of the suppository has passed the sphincter, the rest of the suppository slips in easily—is almost sucked into the rectum—provided the blunt end is introduced first. A pointed tip requires pushing in the entire suppository by insertion of the finger into the rectum and soiling of the finger.

SYSTEMIC ADMINISTRATION

For the systemic administration to children of certain medicines of disagreeable taste, e. g. strychnine, the value of the small suppository still remains to be appreciated by the physician who would make children his friends. It should be the accepted maxim that insulting with nasty medicines the palate of a child is an unpardonable sin—unpardonable because no longer necessary if the physician is acquainted with the resources of modern pharmacy. Even castor oil has been made palatable in the form of the aromatic castor oil of the National Formulary.

There is no reason why such harmless substances as iron, calcium, magnesia or bismuth should ever be given to children—or to adults for that matter—in any other form than that of candy, provided of course the sugar is unobjectionable. Candy medication, which I⁸ had the privilege of studying over twenty years ago, should also be the preferred form of administration for such relatively harmless substances as phenolphthalein, terpin hydrate, acetylsalicylic acid, bromide in the form of calbromen or iodide in the form of caloben. There may be toxicologic reasons why such poisons as arsenic or antimony and potassium tartrate, santonin or strychnine should not be employed as a routine in candy form, though even these might serve extremely well in exceptional cases when used with proper safeguards.

The capsule, a relatively modern form of administration, serves its purpose so well that the maxim might be formulated: For ingestion by mouth, encapsulate everything that can possibly be given in that form. Capsules combine tastelessness with permanence, portability and efficiency.

There are numerous occasions, however, when—for one reason or another—liquid dosage becomes necessary, and for its artistic administration a knowledge of

vehicles is essential. A grant from the American Pharmaceutical Association has made it possible to study this much neglected subject and I am glad to announce that there has resulted from this study a number of new vehicles which will be available in the new National Formulary, soon to be published.

First among those I would call attention to the "iso-alcoholic elixir"⁹ which might perhaps become more popular under the shorter synonym of "iso-elixir." This is a vehicle with the flavor and taste of aromatic elixir, the alcoholic strength of which is adjusted by the pharmacist to the requirements of the medicine for which it serves as a vehicle. The physician experiences difficulty—e g, when he wishes to prescribe tincture of digitalis or tincture of belladonna, the fluidextract of ergot or of cannabis indica—in remembering what percentage of alcohol the vehicle should contain so as to be compatible with these various liquid galenicals. A marked deviation in the percentage of alcohol from that of the menstruum with which the preparation was made introduces an incompatibility and results in the formation of a precipitate that is often poisonous. This dangerous incompatibility can be completely avoided by prescribing iso-alcoholic elixir as the vehicle. The mixtures shown in prescriptions 1 to 4, for instance, might be used.

PRESCRIPTIONS 1 to 4—Mixtures with Iso-Alcoholic Elixir

R	Tincture of digitalis	15 0 cc.
	Iso-alcoholic elixir	to make 60 0 cc
M	Label One teaspoonful in water three times a day after meals	
(For auricular fibrillation)		
R	Tincture of belladonna	10 0 cc.
	Iso-alcoholic elixir	to make 60 0 cc
M	Label One teaspoonful in water after meals and at bedtime	
(For enuresis.)		
R	Fluidextract of ergot	30 0 cc.
	Iso-alcoholic elixir	to make 60 0 cc
M	Label One teaspoonful in water every four hours	(For metrorrhagia.)
R	Fluidextract of cannabis	15 0 cc.
	Iso-alcoholic elixir	to make 60 0 cc
M	Label One teaspoonful in water every two hours until relieved	(For migraine.)

In each instance the physician is assured of a perfectly clear preparation, as all the pharmacist needs to do is mix the low alcoholic elixir and the high alcoholic elixir (N F VI) in the same proportion in which alcohol and water are mixed in the menstruum of the preparation for which it is to serve as a vehicle. For nonextractive substances the lowest alcoholic strength of iso-elixir should be chosen that will yield a perfect solution, for instance as shown in prescription 5. As

PRESCRIPTION 5—Terpin Hydrate in Iso Alcoholic Elixir

R	Terpin hydrate	5 0 Gm
	Iso-alcoholic elixir	to make 60 0 cc
M	Label One teaspoonful in water every three hours	(For cough with profuse expectoration)

terpin hydrate requires strong alcohol for solution the pharmacist will employ the high alcoholic elixir as the vehicle. This will yield an elixir containing a truly medicinal dose of terpin hydrate. The dose of terpin hydrate in the official elixir of terpin hydrate is only one-fourth this quantity per teaspoonful and therefore largely a placebo. The elixir of phenobarbital of the new National Formulary will contain only 0.016 Gm per teaspoonful. Should the physician desire to prescribe a hypnotic dose of phenobarbital per teaspoonful

he may use prescription 6. The pharmacist will then use the high alcoholic elixir, which will make a perfect and permanent solution. If this is not diluted with more than an equal amount of water, it will give a better disguise for the bitter drug than if it is more highly diluted, for the following general principle has

PRESCRIPTION 6—Phenobarbital in Iso-Alcoholic Elixir

R	Phenobarbital	1 5 Gm
	Iso-alcoholic elixir	to make 60 0 cc
M	Label One teaspoonful in an equal amount of water at bedtime	
(For insomnia)		

proved true the best solvent is the best vehicle.¹⁰ This is because a substance will not readily exchange a good solvent for a poor solvent. The truth of this principle is also well illustrated by the fact that bromide is better disguised by an aqueous than by an alcoholic vehicle. It is therefore a mistake to prescribe an elixir of

PRESCRIPTION 7—Potassium Bromide in Syrup of Glycyrrhiza

R	Potassium bromide	30 0 Gm
	Anise water	30 0 cc
	Syrup of glycyrrhiza	to make 120 0 cc
M	Label One teaspoonful in milk after meals and at bedtime	
(Nerve sedative)		

bromide when syrup of glycyrrhiza (prescription 7) will yield a more palatable preparation.

The syrup of glycyrrhiza¹¹ is an admirable vehicle for salines, partly because of its colloidal nature and partly because of its double sweetness—the immediate sweetness of the sugar and the lingering sweetness of the glycyrrhizin.

PRESCRIPTION 8—Urea and Syrup of Acacia

R	Urea	15 0 Gm
	Syrup of acacia	to make 60 0 cc
M	Label One teaspoonful in a wineglassful of water every two hours	(As a diuretic.)

Another illustration of the value of colloidal nature in disguising tastes is found in the syrup of acacia, the formula for which has been improved by the addition of sodium benzoate for preservation and of vanilla for flavoring. We¹² find that this syrup is a good disguising vehicle for substances of rather burning taste, such as urea (prescription 8).

PRESCRIPTION 9—Hydrochloric Acid and Raspberry Syrup

R	Diluted hydrochloric acid	5 0 cc
	Raspberry syrup	to make 60 0 cc
M	Label One teaspoonful in a wineglassful of water taken through a straw after meals	(For hypochlorhydria)

For a sour taste, fruit syrups¹³ form the most eligible vehicles. Thus, for the administration of hydrochloric acid, raspberry syrup is excellent (prescription 9).

What could make a nicer disguise for the syrup of hydriodic acid than the new cherry syrup of the National Formulary as used in prescription 10? This

PRESCRIPTION 10—Hydriodic Acid and Cherry Syrup

R	Syrup of hydriodic acid	10 0 cc
	Cherry syrup	to make 60 0 cc
M	Label One teaspoonful in a wineglassful of water three times a day after meals	(In chronic bronchitis. For a child 5 years old)

true fruit cherry syrup, being so much more pleasant, should supplant the old-fashioned wild cherry syrup, which—being made of wild cherry bark—has an astringent and often decidedly nasty taste.

⁹ Fantus, Bernard and Snow, C. M. Iso-Alcoholic Elixirs. *J Am Pharm A*, 10: 277, 1921. Fantus, Bernard. Iso-Alcoholic Elixirs. *ibid*, 9: 708, 1920. Fantus, Bernard, Dyniewicz, H. Elixir of Phenobarbital. *J Am Pharm A*, 23: 127 (Feb.) 1934. ¹¹ Fantus, Bernard, Dyniewicz, H. A. and Dyniewicz, J. M. The Glycyrrhiza Vehicles. *J Am Pharm A*, 23: 915 (Sept.) 1934. ¹² Fantus, Bernard, Dyniewicz, H. A. and Dyniewicz, J. M. Aromatic Syrup of Acacia. *J Am Pharm A*, 23: 812 (Aug.) 1934. ¹³ Fantus, Bernard, Dyniewicz, H. A. and Dyniewicz, J. M. Fruit Syrups. *J Am Pharm A*, 24: 46 (Jan.) 1935.

The syrup of cinnamon¹⁴ of the new National Formulary is the best vehicle that I know for sodium salicylate or for iron and ammonium citrate. The syrup of cinnamon listed in the fifth edition of the National Formulary was made from cinnamon bark, which contains tannic acid and is rather unpalatable as well as decidedly incompatible with either of these medicinal agents. The new syrup of cinnamon may be used as shown in prescriptions 11 and 12 with perfect results, but N F VI should be specified until the new formula has become well established.

PRESCRIPTIONS 11 AND 12—*Syrup of Cinnamon (N F VI)*

R	Sodium salicylate	10 0 Gm
	Potassium bicarbonate	10 0 Gm
	Cinnamon water	60 0 cc
	Syrup of cinnamon (N F VI)	to make 120 0 cc
M	Label: Two teaspoonfuls in a glassful of seltzer water every hour	
(For	acute articular rheumatism)	
R	Iron and ammonium citrate	10 0 Gm
	Water	100 cc
	Syrup of cinnamon (N F VI)	to make 120 0 cc
M	Label: One tablespoonful in a glassful of water three times a day	
after	meals (For anemia)	

The aromatic syrup of eriodictyon is a veritable pharmaceutical masterpiece, for the elaboration of which—I regret to say—I can claim no credit. We¹⁵ have, however, discovered that the reason for its efficiency in the disguising of the bitterness of the alkaloids is a resin that combines with the alkaloid to form a precipitate so easily soluble in acid as well as in alkali that it becomes active in the system. There is a small quantity of alkali present in the syrup, just enough to keep the resin in solution but not enough to decompose the alkaloidal compound. As used in prescription 13 it subdues the bitter taste of quinine better than any other liquid form of administration known to me.

PRESCRIPTION 13—*Quinine and Eriodictyon*

R	Quinine ethylcarbonate	5 0 Gm
	Aromatic syrup of eriodictyon	to make 60 0 cc
M	Label: One teaspoonful every four hours (For malaria in a child)	

Codeine phosphate and even strychnine sulphate in children's dosage may be given surprisingly well disguised by this syrup, employed as shown in prescriptions 14 and 15.

PRESCRIPTIONS 14 AND 15—*Aromatic Syrup of Eriodictyon*

R	Codeine phosphate	0 10 Gm
	Aromatic syrup of eriodictyon	60 00 cc
M	Label: One teaspoonful with water every two to three hours as required (For excessive cough)	
R	Strychnine sulphate	0 015 Gm
	Aromatic syrup of eriodictyon	120 00 cc
M	Label: One teaspoonful in water three times a day after meals (As a tonic)	

Eriodictyon is suitable as a disguising vehicle not only for alkaloids but also for other substances of alkaloid-like nature, such as amidopyrine.¹⁶ After considerable experimentation with this substance we

PRESCRIPTION 16—*Amidopyrine and Eriodictyon*

R	Amidopyrine	2 5 Gm
	Alkaline elixir of eriodictyon (Recipe Book II)	60 0 cc
M	Label: One teaspoonful in water every two to four hours as required (Analgesic)	

devised a formula for an alkaline elixir of eriodictyon, containing 50 per cent alcohol (the formula for which is to be contained in "Recipe Book, II") which seemed to answer the purpose best. This might be used as shown in prescription 16.

HYPODERMIC ADMINISTRATION

Ampules containing multiple doses should be a means of considerable economy in the hypodermic administration of fluids, the high price of ampules containing single doses being largely due to the labor involved in their production and the high percentage of breakage of these fragile products. The chief objection to the use of ampules containing multiple doses is the danger of contamination of the contents if strict asepsis is not maintained in their use. The new National Formulary will contain formulas for a liberal selection of ampule solutions—those most commonly employed—and a statement of the usual concentration of solution and the average dose most frequently used. But putting up these solutions in ampules containing several doses, with the addition of a bacteriostatic agent to the solution—as will be required by the National Formulary—and by the use of an aseptic technic, a great deal of money can be saved without adding any element of danger to the administration.

Hypodermic injection by means of an automatic syringe, such as Busher's,¹⁷ is a boon for the timid person who requires the self administration of hypodermic injections, as of insulin in cases of diabetes mellitus and of epinephrine in cases of bronchial asthma. The self administration of hypodermic injections of morphine should of course be strictly taboo.

The introduction of a large quantity of fluid subcutaneously and intravenously has been one of the most important therapeutic advances of recent years. It was my privilege to be of assistance in establishing a laboratory for the preparation of solutions for injection at Cook County Hospital. That laboratory now produces almost 5,000 disks a month and at a net reduction in cost of about 1,500 dollars per month. It also has enabled us to make certain observations that are sufficiently interesting and important to be reported on in a preliminary way. We have confirmed abundantly the proposition that there are no so-called reactions if water that is freshly distilled is employed for the production of these solutions. The cause of these "reactions" is the bacterial life which finds distilled water so good a culture medium that a few spores unavoidably and invariably introduced into it during or after distillation produce within a few hours enough bacterial poisons to cause chill and fever. This occurs even if the water has been triply distilled but is not employed immediately afterward. Water distilled merely once and employed immediately for the preparation of the solutions and sterilized without delay is perfectly safe.

We are carrying on a study at Cook County Hospital of what happens to the solutions introduced into the body of patients in the Recovery Ward, a department set aside for the care of patients the first day after capital operations. We have found that the sicker the patient, the smaller the percentage of the injected fluid eliminated, so that patients who eliminate only 10 per cent or less of the fluid injected have a mortality rate as high as 75 per cent. The death rate declines progressively from this point as the percentage of elimination increases. It must be concluded from this that the sicker the patient, the more conservative should be the total quantity of fluid administered, unless there exists in the patient an extreme degree of hypohydration, and this should be antagonized by a preoperative rather than a postoperative intake of fluid.

17 Busher, Herbert. *Automatic Hypodermic Syringe for Self Administration of Insulin and Other Uses* J. A. M. A. 102: 1152 (April 7) 1934.

Equally striking have been the results of a study of the elimination of chloride in the urine. As a result of observations made on over a thousand patients with the help of Dr Robert Morse at Cook County Hospital, whose observations are to be published shortly, we are able to formulate the rule that the postoperative mortality rate is in inverse proportion to the percentage of chloride in the urine. Patients who passed less than 01 per cent of chloride in the urine had a mortality rate of 45 per cent, and the mortality rate declined as the percentage of chloride in the urine passed postoperatively increased. The cause of this is now under investigation. It may be due to preoperative salt starvation, which should be antagonized by adequate ingestion of salt before operation. It may be due to loss of salt in exudate, by emesis or by sweating. In any case, in view of these observations it must be concluded that determination of the chloride in the urine is an important measure in the preoperative as well as postoperative control of patients, and that postoperative hypochloruria should be promptly antagonized by the introduction of hypertonic salt solution until this deficiency is corrected.

We have also found that most of our patients received postoperatively more dextrose than they were able to assimilate when they were given intravenously several liters of a 5 per cent solution of dextrose. This is objectionable, if for no other reason than that the dextrose passing into the urine carries water along with it, wasting that much of the fluid introduced. The incidence of postoperative glycosuria has been much decreased in the Recovery Ward by using a mixture of equal quantities of physiologic solution of sodium chloride and a 5 per cent solution of dextrose, which is probably the best fluid for routine injection postoperatively. The urine of each patient receiving dextrose should be tested for sugar and, if sugar is passed in the urine in spite of the fact that the patient has not received a quantity excessive under ordinary circumstances, an indication for insulin is present.

SCLEROSING INJECTIONS

There is no reason why the trained surgeon should not add the needle to his resources for bloodless operations. The injection of varicose veins has been established as an orthodox procedure. A solution of quinine urethane is the safest injection fluid to employ not only because the quinine is bactericidal and prevents infection but also because it is antiphagocytic and thus antagonizes digestion and loosening of the fibrinous thrombus that is formed and prevents the development of embolism.¹⁸ Its only disadvantage is that some persons have an idiosyncrasy to quinine. In these cases solution of salt, sugar or soap must be used. Sodium morrhuate, the soap that seems to be in favor at present, is probably safer to use if 0.5 per cent of phenol is added to act as a bacteriostatic.

A patient with hydrocele should perhaps no longer be operated on. After withdrawal of the fluid a 2 per cent solution of procaine is injected, allowed to remain for a few minutes and then withdrawn, followed by the injection of possibly 8 cc of a 5 per cent solution of sodium morrhuate containing 0.5 per cent of phenol. This is permitted to remain for one minute, then half of the amount is withdrawn and a snug suspensory bandage is applied.¹⁹

The injection treatment of reducible hernia still remains to be conquered by the medical profession. The problem here is more complicated, but there can be no doubt that a certain percentage of patients with hernia can be cured by appropriate injection treatment in an ambulant and much less expensive manner than by open surgery.

An almost unlimited field for therapeutic exploitation has been opened up by the injection of alcohol and of other nerve destructive agents in the treatment of intractable pain²⁰ and to antagonize excessive nerve reactions. Thus, a few drops of absolute alcohol injected at exactly the right point in the subarachnoid space will relieve for many months the pain in the back, pelvis and legs in cases of cervical or rectal carcinoma. Injection of 60 per cent alcohol into a sensory nerve or of 33 per cent alcohol into a mixed nerve is capable of inducing therapeutic nerve block.²¹ In consequence, constant and intractable pain should be considered an indication for nerve block somewhere in the afferent tract rather than for the indiscriminate administration of analgesics.

It is freely admitted that many of the advances here discussed still lie in the future. That is but natural, for as "hope springs eternal in the human breast," and "man never is but always to be blest," so advance never is but always to be made.

719 South Ashland Boulevard

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS

HOWARD A. CARTER, Secretary

DR. WARREN'S INFRA-RED SITZ BATH NOT ACCEPTABLE

Manufacturer: Electrical Research Laboratories, Warren, Pa.

The so-called Dr. Warren's Infra-Red Sitz Bath may be described as a stool with an infra-red heating element located in the base. The patient sits on the ringlike seat, and a large gown, which reaches to the floor, covers all except his head. The heat from the electrical heating element passes up through the center as well as around this seat and the warm air is confined under the gown.

Advertising matter for this unit contains many unwarranted statements, some of which are as follows:

Men Enjoy this Convenient and Effective Method of Rejuvenation. Most effective and practical method of stimulating the genital organs. Men notice immediate results in rebuilding virility.

There is no reason why you should start to slow down at forty. Dr. Warren's Infra-Red Sitz Baths are recommended for the relief of arthritis, rheumatism, gout, menstrual pains, disorganized periods, sciatica, neuralgia, kidney and bladder trouble, prostate disorders, loss of vitality, bronchitis, insomnia, skin disorders, common colds, alcoholism, lumbago, catarrh, asthma, auto-intoxication.

Evidence substantiating these claims has not been submitted to the Council.

Under the caption "Every Man or Woman Can Preserve Physical Vigor and Health with Frequent Use of Dr. Warren's Infra-Red Sitz Bath," is recorded:

"The healthful glow following this treatment is the reaction carrying the blood away from the head and affected parts, and soon you feel an invigorated sensation that really makes you feel like yourself again. For women who have chronic catarrh of the organs of generation for men who suffer from prostate trouble, Dr. Warren's Infra-Red Sitz Bath produces a soothing and relaxing effect. There is no need for any woman to suffer from periodic pain when a few treatments in her home will bring relief. Try it! Put this electrical health building Bath to the

crucial test Let it chase away the headache the backache or tired feeling—let it revive you from the fatigue of the day's work
 "The common cold never attacks the body that is free of toxins"

The Electrical Research Laboratories promotes a special club, and this appliance is sold directly to the club purchasers with a ten-day money refund rejoinder

The foregoing report was submitted to the Electrical Research Laboratories for comment prior to publication The company replied that the Dr Warren's Infra-Red Sitz Bath had never been presented to the Council, that the company had never requested the Council to consider approval of this appliance, that the outfit is not merchandized through the medical profession, and that the company did not feel that the Council had any right to issue any report without their permission

The Council maintained, however, that the policies of the firm in marketing this device were detrimental to rational therapeutics and to the public welfare Furthermore, the Council reasoned that promotional literature of this kind constituted an appeal to the public with arguments that are unscientific and may harmfully enhance a feeling of false security on the part of a person acquiring the device

Since the aforementioned reply of the firm added nothing to the original report, the Council reaffirmed its previous decision and voted not to include Dr Warren's Infra-Red Sitz Bath in its list of accepted devices

LIFE LITE NOT ACCEPTABLE

Manufacturer Ultra-Violet Home Products, Inc., Los Angeles

The Life Lite is a so called home model sunlamp It is of the mercury glow type, low vapor pressure, and most of the ultraviolet radiation energy is concentrated in the band known as the 2,735 A line

Many requests have come to the office of the Council on Physical Therapy for information concerning the efficacy of this lamp The advertising matter referred to the office by inquirers was given careful consideration by the Council Several misleading and unsubstantiated statements were noted For example, "Less tendency to catch cold," "Build up body resistance against disease," "Relieve pain and itching" and "Destroy most germs" Nothing in the way of conclusive evidence has been submitted or referred to the Council that substantiates these statements

The Life Lite was also recommended for arthritis, asthma, bronchitis, burns, chilblains, falling hair, and underweight children Likewise the Council is without conclusive evidence to substantiate the efficacy of the lamp in the aforementioned conditions

In view of the objectionable advertising matter, the Council voted not to include the Life Lite lamp in its list of accepted devices for physical therapy

MAZDA CX AND MAZDA C LAMPS ACCEPTABLE

Manufacturer General Electric Company, Incandescent Lamp Department, Cleveland

These lamps are recommended by the firm as sources of infra-red energy and may be used for therapeutic purposes They come in various sizes

Mazda CX Lamps

Mazda CX Lamps, 60 250 and 500 watts, the Mazda C Lamps, 1 000 and 1,500 watts For the best results they should be installed in a properly designed reflector From four to six 60-watt lamps may be used satisfactorily in a simple electric baker

The Mazda CX and Mazda C Lamps are of the tungsten filament variety and have a

greater tissue penetrating power of the infra-red radiation than that of the carbon filament lamps, watt for watt.

In view of the usefulness of these lamps for therapeutic purposes, the Council voted to include the Mazda CX and Mazda C Lamps in its list of accepted devices

PROMETHEUS PROFESSIONAL INFRA RED UNIT ACCEPTABLE

Manufacturer The Prometheus Electric Corporation, New York

This office unit is recommended for use wherever infra red therapy is indicated The reflector is 16 inches in diameter mounted on a swivel arm, and a three-legged base equipped with rubber-tired casters The stand is chromium plated and adjustable in height from 20 inches to 78 inches

Electrical measurements on this unit indicate that it draws 1,100 watts at 9.4 amperes on a 115 volt line.

The lamp was investigated to determine whether there were any "hot spots" within a circle of one meter The difference in variation in radiation intensity between the center section and the diameter was found to be 26 per cent This measurement was determined by means of a radiometer

The reflector is chromium plated and the burner is of the refractory type with the resistance wires embedded within the ceramic material

Prometheus Professional Infra Red Unit

This unit has been tried out for one month in a clinic acceptable to the Council In view of the report submitted by this clinic, the Council on Physical Therapy voted to include the Prometheus Professional Infra Red Unit in its list of accepted devices

BENEDICT-ROTH METABOLISM APPARATUS ACCEPTABLE

Manufacturer Warren E Collins, Inc., Boston

The Benedict-Roth apparatus is a closed circuit, spirometer type metabolimeter of sturdy construction The weight of the outfit, including the water in the spirometer, is 33 pounds The water required weighs 5 pounds

All exposed parts are chromium plated or made of rust resisting material The entire machine is mounted on a sturdy base, which can be readily handled and can be conveniently leveled by two thumb screws

Suspended in a water jacket in the conventional manner, the spirometer bell is counterbalanced accurately by means of a chain which runs over a pulley wheel to a counterweight, the chain being so arranged that it balances the weight of the bell at all positions Attached to this counterbalance weight is the marking pen of a simple capillary type, which will hold enough ink for several tests It swings from a pivot, which allows it to fall against the surface of the kymograph drum when writing

A spring driven clock mechanism contained in the base of the machine turns the kymograph drum This mechanism is controlled by a small lever in a convenient position at the side of the base The kymograph drum is precisely centered It does not deviate during revolution and can be easily removed for replacing drum paper A metal encased thermometer is attached to the top of the spirometer bell

Two large rubber tubes leading from the spirometer chamber to the mouthpiece are held by a flexible metal support. They are attached to the mouthpiece by a metal device, which contains a circular valve which, by a 90 degree turn, allows the patient to breathe either the air of the chamber or the outside air The patient inhales directly from the spirometer chamber and exhales through soda lime for the removal of the carbon dioxide. Both inlet and outlet flutter valves and the soda lime container are placed within the spirometer bell so that the slight leaks inherent in the Sadd valves do not affect the accuracy of the apparatus, and the soda lime container on this account needs not be absolutely tight and so makes a sliding fit over the inlet pipe, allowing an easy removal for refilling

In a clinic acceptable to the Council, the Benedict Roth Metabolism Apparatus was investigated. The kymograph clock mechanism was tested and found to gain not more than one second in 360 seconds, the time of the test runs This was considered well within that necessary for clinical accuracy

The spirometer bell volume was found to be 99.5 per cent accurate by actual removal of definite volumes of air from the bell. This shows the machine to be more accurate than the graph since the graph can be read accurately to only 1 mm. Variations greater than this may occur between successive respiratory movements of any individual. All the valves were tested and found to be leak proof or functionally perfect. The flutter valves do not hamper the movement of the air through the machine. The entire apparatus was tested for leakage under 10 to 15 pounds pressure and was found to be leak proof. The spirometer bell required a pressure of only 1 cm. of water to move it freely.

Calculations are simplified in that the charts for temperature and pressure correction, body surface area, and calories per square meter per hour are on the opposite side of the kymograph drum paper. This drum paper contains all information for calculations and data concerning the patient and actual test tracings so that when it is folded once it is of appropriate size for filing. The calculations are simplified in that there is needed only two multiplications, one subtraction, and one division to derive the basal metabolic rate of the patient. Tables and charts used in calculations have been checked as to origin and accuracy and found to be authentic and accurate within practical limits.

In view of the favorable report, the Council on Physical Therapy voted to include the Benedict-Roth Metabolism Apparatus in its list of accepted devices.

"STANDARD JUNIOR" DIATHERMY ACCEPTABLE

Manufacturer: High Tension Corporation, 118 West Twenty-Second Street, New York

This machine generates and delivers the standard d'Arsonval current for medical and surgical diathermy practice. It is of the spark gap type. The spark gap assembly consists of ten gaps in a series. Control of gaps is so arranged that they can be opened in any order, all simultaneously or only one at a time.

It operates on 110 volts, 60 cycle alternating current, and can be obtained for other voltages or frequencies. The transformer is oil immersed in a galvanized steel tank. The condensers in this apparatus are two Leyden jars made of pyrex glass coated on the outside with tinfoil, which in turn is covered with sheet copper. The inner conducting medium of the Leyden jar is salt water—about 45 ounces. Contact with the salt water is made through carbon rods mounted in a hard rubber cap that fits over the top of the jar. The resonator is of the flat pancake type containing both the d'Arsonval and Oudin windings.

Standard Junior Diathermy

The Standard Junior Diathermy was investigated in a clinic acceptable to the Council. Tests were made by running the machine wide open, with the controls set at

the maximum, for three hours and fifteen minutes. The output terminals were short circuited to deliver a current of 2,500 milliamperes. At the start the interior temperature of the cabinet was 77 F. At the end of this three hour and fifteen minute period the temperature rose to 102 F. Before the test a large thermometer was inserted through the air vent of the transformer case so that it came in contact with the transformer itself and the temperature reading was 71 F. At the end of the same three hour and fifteen minute test run the temperature was 126 F. These figures indicate a rise of 25 degrees in the temperature inside the cabinet, and a rise of 55 degrees F in the temperature within the transformer case and probably of the transformer itself, as the thermometer was put in actual contact. These temperature limits appear to be in accordance with the Council requirements.

HARBORVIEW DIVISION

The machine was employed in the treatment of many clinical cases characteristic of a large city clinic. The investigator reports the performance satisfactory. As a surgical diathermy machine, the unit was reported as giving good service.

In view of the foregoing report, the Council voted to include the "Standard Junior" Diathermy in its list of accepted apparatus.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary

MERCUROCHROME (See New and Nonofficial Remedies, 1935, p 309)

The following dosage form has been accepted

Mercurochrome Applicators Mercurochrome (H W & D) 10 per cent and acacia dried on one end of 3 inch wooden sticks

Prepared by the Arzol Chemical Company, Nyack, N Y (J. Sklar Manufacturing Company, Brooklyn, N Y distributor)

SODIUM CACODYLATE (See New and Nonofficial Remedies, 1935, p 88)

The following dosage form has been accepted

Ampules Sodium Cacodylate Mulford 2 grains 1 cc

Prepared by Sharp & Dohme, Philadelphia

SODIUM CACODYLATE (See New and Nonofficial Remedies, 1935, p 88)

The following dosage forms have been accepted

Ampul Solution Sodium Cacodylate 0.2 Gm (3 grains) 1 cc

Prepared by the U S Standard Products Co., Woodworth, Wis.

Ampul Solution Sodium Cacodylate 0.32 Gm (5 grains) 1 cc

Prepared by the U S Standard Products Co., Woodworth, Wis.

Ampul Solution Sodium Cacodylate 0.45 Gm (7 grains) 1 cc

Prepared by the U S Standard Products Co., Woodworth, Wis.

Ampul Solution Sodium Cacodylate 0.2 Gm (3 grains) 5 cc

Prepared by the U S Standard Products Co., Woodworth, Wis.

Ampul Solution Sodium Cacodylate 0.32 Gm (5 grains) 5 cc

Prepared by the U S Standard Products Co., Woodworth, Wis.

Ampul Solution Sodium Cacodylate 0.45 Gm (7 grains) 5 cc

Prepared by the U S Standard Products Co., Woodworth, Wis.

DIPHThERIA TOXOID, ALUM PRECIPITATED (REFINED) (See New and Nonofficial Remedies, 1935, p 395)

Parke, Davis & Company, Detroit

Diphtheria Toxoid Alum Precipitated (Refined) P D & Co. (See New and Nonofficial Remedies, 1935, p 397).—Also marketed in packages of one 0.5 cc vial and in packages of one 5 cc vial containing one and ten doses respectively.

ERYSIPELAS STREPTOCOCCUS ANTITOXIN (See New and Nonofficial Remedies, 1935, p 371)

Lederle Laboratories, Inc., Pearl River, N Y

Erysipelas Streptococcus Antitoxin Globulin Lederle Modified—An antitoxin prepared by immunizing horses against erysipelas toxin and cultures of erysipelas streptococcus through the injection of gradually increasing doses of erysipelas toxin. The product differs from Erysipelas Streptococcus Antitoxin (Lederle) Refined and Concentrated in that it is refined by a different method. The process of refinement is based chiefly on a controlled method of selective digestion of the proteins of the immune horse blood with pepsin. As a result of this process up to 90 per cent of the coagulable protein may be digested; a smaller portion is precipitated and the remainder a pseudoglobulin fraction is purified first by ordinary filtration and then by ultrafiltration and dialysis. The resultant solution is sterilized and subjected to the tests prescribed by the National Institute of Health. While antitoxin processed in this manner is stated to produce fewer reactions than antitoxin processed by the usual salting out method it is still a protein solution and all customary precautions should be taken to avoid or care for serum reactions.

Erysipelas streptococcus antitoxin globulin Lederle-Modified is administered in early cases of moderate severity in one basic dose (the entire content of one syringe as marketed) intramuscularly repeated if necessary at intervals of twenty-four hours until the erysipelatosus blush disappears in late and severely toxic cases larger dosage with a shorter interval between doses may be used. It is marketed in packages of one syringe containing one basic dose.

Committee on Foods

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION

RAYMOND HERTWIG Secretary

Distributors—1 and 9 National Food Products Corporation, New York 2 The Herrman Company, Paterson, N J 3, 4, 5, 7 and 8 Ridenour-Baker Grocery Company, Kansas City, Mo 6 The Lehmann Higginson Grocer Company, Wichita, Kan

Packer—Hawaiian Pineapple Company, Ltd San Francisco

Description—Canned pineapple packed in concentrated pineapple juice with added sucrose. The same as Dole Hawaiian canned pineapple products (THE JOURNAL, April 8, 1933, p 1106, and April 29, 1933, p 1338)

KRIM-KO CHOCOLATE FLAVORED DRINK

Bottlers and Distributors—

Olmstead & Son, Coldwater, Mich

Kalamazoo Creamery Co, Kalamazoo, Mich

Licensor—Krim-Ko Company, Chicago, manufactures the Krim-Ko Chocolate Flavored Drink Base and licenses its use, the name Krim-Ko and standard advertising under definite contract conditions

Description—Pasteurized chocolate flavored sweetened milk, contains milk, sucrose, chocolate and cocoa, tapioca flour, salt and traces of tartaric acid and agar, flavored with vanilla, vanillin and coumarin See Krim-Ko Chocolate Flavored Drink (THE JOURNAL, June 30, 1934, p 2187)

ANTHONY'S PASTEURIZED HOMOGENIZED MILK

Distributor—Anthony Pure Milk Company, Inc., Nashville, Tenn

Description—Bottled, pasteurized, homogenized milk.

Preparation—Milk obtained from producers under supervision of the Tennessee State Department of Health and the City of Nashville Department of Health is tested for milk fat, sediment and its reaction to methylene blue Milk passing these tests is pasteurized by the holding method (63 C for thirty minutes), homogenized at 3,000 pounds pressure per square inch, cooled and filled in bottles by the usual procedure (THE JOURNAL, Sept 1, 1934, p 681)

Analysis—Standardized to contain not less than 42 per cent of milk fat

Calories—0.7 per gram 20 per ounce

Claims of Manufacturer—The cream does not separate The curd formed in the stomach is softer than that from unhomogenized milk.

CELLU ROYAL ANNE CHERRIES PACKED IN WATER WITHOUT ADDED SUGAR OR SALT

Distributor—The Chicago Dietetic Supply House, Inc., Chicago

Packer—Eugene Fruit Growers Association, Eugene, Ore.

Description—Canned cooked Royal Anne Cherries packed in water without added sugar or salt.

Manufacture—The method of manufacture is essentially the same as for Cellu Juice-Pak Royal Anne Cherries (THE JOURNAL, Aug 25, 1934, page 564) with the exception that the fruit is packed in water

Analysis (submitted by distributor) —

OLD ANTIQUE PALE DRY GINGER ALE

Manufacturer—Blue Seal Extract Company, Cambridge.

Description—Ginger ale, a carbonated beverage prepared from water, sucrose, citric acid, extracts of ginger root, grape and apple, oils of lime and orange and caramel color

Manufacture—Ginger root extract is prepared by steeping macerated ginger root in boiling water An equal volume of ethyl alcohol and infusorial earth is added to precipitate out gums and resins, and the extract solution is decanted and filtered The citrus oils and fruit extracts are added to the clear filtrate. The other ingredients in definite proportions are added to the flavoring solution. The final mixture is filtered, filled into bottles, cooled, five volumes of carbon dioxide are introduced under 70 pounds pressure and the bottles are sealed City water treated with ultraviolet rays is used.

Analysis (submitted by manufacturer) —

	per cent
Moisture	92.6
Total solids	7.4
Ash	0.02

Claims of Manufacturer—Complies with the United States Department of Agriculture definition for ginger ale.

SUNSHINE BRAND PIMIENTOS

Manufacturer—Pomona Products Company, Griffin, Ga

Description—Canned cooked pimiento (sweet red) peppers. No added water or salt

Manufacture—Pimiento peppers, grown under contract conditions, are inspected, fire roasted to loosen the skins, thoroughly washed to remove skins, again inspected, hand packed in cans and processed at 100 C. No water, salt or other material is added

<i>Analysis</i> (submitted by manufacturer) —		per cent

Vitamin C. Biologic assay shows that canned pimiento pepper approximates fresh grapefruit in vitamin C, and therefore is an excellent source

BANNER EVAPORATED MILK

Distributor—Challenge Cream and Butter Association, Los Angeles

Packer—The Milk Producers Association of Central California, Modesto, Calif

Description—Sterilized, unsweetened, evaporated milk

Manufacture—Milk deliveries are tested for odor by company inspectors immediately on delivery, and for bacterial content once weekly by a state examiner, only milk of the highest grade is used. The milk is preheated to 82-88 C, partially evaporated under vacuum, homogenized, standardized to 78 per cent milk fat and 26 per cent total solids content chilled to 40 C, held at this temperature for six to eight hours, canned and sterilized at 119 C for sixty minutes according to standard procedures

<i>Analysis</i> (submitted by distributor) —		per cent
Moisture	73.7	
Total solids	26.3	
Ash	1.4	
Fat	7.9	
Protein (N \times 6.38)	7.3

- 3 ROYAL CLUB PREMIUM BAKING CHOCOLATE
- 4 WADHAMS PREMIUM BAKING CHOCOLATE

Distributor—1 Arrowhead Stores Corporation, Buffalo 2 New England Stores Service Corporation, Boston, Worcester and Springfield, Mass 3 Mason Ehrman & Company, Portland Ore. 4 Wadhams & Company, Inc., Portland Ore.

Packer—Moffat, Inc., South Boston, Mass

Description—Ground cacao nibs or "chocolate liquor" in cake form. Same as Moffat Cooking Chocolate, Unsweetened (THE JOURNAL, Jan 20 1934, p 213)

Claims of Manufacturer—Conforms to the United States Department of Agriculture definition and standard

CELLU RED PITTED CHERRIES PACKED IN WATER WITHOUT ADDED SUGAR OR SALT

Distributor—The Chicago Dietetic Supply House, Inc., Chicago

Packer—Reynolds Preserving Company, Sturgeon Bay, Wis

Description—Canned cooked red Wisconsin cherries packed in water without added sugar or salt.

Manufacture—The method of manufacture is essentially the same as for Cellu Juice-Pak Royal Anne Cherries (THE JOURNAL, Aug 25, 1934, page 564) with the exception that the fruit is pitted and packed in water

<i>Analysis</i> (submitted by distributor) —		per cent
Moisture	88.0	
Total solids	12.0	
Ash	0.4	
Fat (ether extract)	0.5	
Protein (N \times 6.25)	0.6	
Reducing sugars as invert sugar	8.5	
Sucrose	0.0	
Crude fiber	0.1	
Carbohydrates other than crude fiber (by difference)	10.4	

Calories—0.5 per gram 14 per ounce

Claims of Distributor—For diets in which sweetened fruit is proscribed

VEE VO

Manufacturer—Titman Food Products Incorporated, New York

Description—Mixture of cane sugar, breakfast cocoa, malted milk, dried egg yolk (1 per cent) whole milk powder, malt extract, vanillin and salt

Manufacture—The ingredients in formula proportions are mechanically mixed and automatically filled into cans, which are vacuumized and sealed in an atmosphere containing 85 per cent of carbon dioxide

<i>Analysis</i> (submitted by manufacturer) —		per cent
Moisture	1.8	
Ash	1.7	
Fat (ether extract)	7.2

SATURDAY, SEPTEMBER 14, 1935

NOISE AND HEALTH

The furor and the clangor of modern life sound a note far different from the tones heard by the people of previous centuries. We think of ancient man as living in an atmosphere of quietude with only the songs of the birds, the hum of the bee, the murmur of the brook and the occasional vocalization of wild animals impinging on his tympanum. Yet no doubt in the middle ages, when men strutted about in mail armor and beat on shields with their swords, the apparatus of hearing must have had some alarming sensations. Nowadays the shrieking of train and steamboat whistles, the rumble of the wheels of street cars, the sirens of police motorcycles, fire apparatus and street car, gas and electric repair trucks, the tooting and fluting of motor horns and the programs emanating from innumerable radio devices tend to produce a concatenation of sounds beyond anything that may have disturbed people fifty years ago.

In Great Britain they are taking their noise situation quite seriously. In June an exhibit was held by the Anti-Noise League at which Mr. H. G. Wells presided and at which Lord Horder spoke on the relation of noise to health.¹ Mr. H. G. Wells began by pointing out that there was a great deal to be said for noise. Indeed, if he had to choose between a silent world and the world as it is today, he would reluctantly choose the latter. He ventured the interesting observation that he could not work in absolute silence, preferring an undercurrent of noise. If he could not hear a distant piano or the subdued sounds from the street he was understimulated. Several American writers have pointed out that they like to listen to the radio while writing or working, apparently being able to focus their attention fully on the task in hand while subconsciously listening to the sounds coming from the radio horn. Perhaps satirically, Mr. Wells said that the noises of towns were not to be compared with the dreadful noises which pursued one in the country. No one who had not heard it could imagine how exasperating the nightingale

could be when heard all night long, followed at dawn by the twitterings of birds. "What humanity needs," said Mr. Wells, "is not to banish noise but to control it." Yet he felt that people ought to be able to achieve an auditory isolation exactly as they are able to detach themselves visually from others and that some method of sound-proofing our lives is required.

From the scientific point of view, Lord Horder pointed out that, of course, every one recognizes the relationship of noise to the loss of sleep or to the disturbance of sleep. Nature has arranged to protect us against many of the incidents of life. If light is too sudden or glaring, the rapid action of the eyelid saves the delicate curtain of the retina from harm. A crash in our vicinity causes us to shrink back from danger. There does not appear, however, to be any good reflex mechanism for the protection of the human ear, at least not thus far developed in the evolution of the human being. Perhaps nature never realized that human beings would produce machines as vast and powerful as those we now have. Sudden noise is certainly a disturbance affecting nerve integrity. Some individuals are much more susceptible to noise than are others. Civilized man is more sensitive to noise than uncivilized man, and the child is less sensitive to it than the adult. Various noises affect different people in different ways. A man who may not object to a two hour session with the radio will find the whining of a child or the whimpering of a puppy acutely annoying. Motor horns are a necessity, but certainly there is no need for such horns as one sometimes sees advertised with the claim that the sound can be heard three miles away. Neither is there a necessity for the raucous, shrieking, ear-splitting devices with which some motorists equip themselves.

The abatement of noise is another example of the social control necessary in a changing civilization. As man is becoming more and more closely crowded, as the machine is introduced into human life, as every one of the special senses of mankind is subjected to new stresses and strains, organized civilization must pay attention to these new factors for the benefit of mankind as a whole. Mr. H. G. Wells expressed a doubt as to whether life was more exacting now than in bygone times. He said the trouble was that people tried to get much more out of life than they had ever attempted before. Men of 60 or 70 nowadays are trying to play the part which men of 30 or 40 played in the past. Yet Mr. Wells failed to take into account that modern medicine has made it possible for more human beings to live to the age of 60 or 70 and to live useful lives to advanced years. Of this, Mr. Wells is himself an example. The civilized world of a century or two centuries ago was dominated by young men because there were few old persons available to carry on the work of the world. Today the majority of people live to the age of 60 and the experienced brain has advantage over that of youth. Yet continued gains

¹ Noise Abatement. Brit. M. J. 2:19 (July 6) 1935.

can be made only by protecting the brains and the senses of man against such hazards as are easily preventable and of little significance for human advancement. Of these, noise is certainly one with which we may most easily dispense.

ACTION OF DIURETICS

The clinical use of diuretics has fortunately been accompanied by careful studies of their mode of action. Exact agreement is not yet in evidence, but enough is now known to increase materially confidence in therapeutic administration.

Two groups of diuretics—the xanthine derivatives and the mercurials—have received most clinical and experimental attention. The physiologist is interested primarily in the place and mechanism of action, the clinician in the indications and contraindications for the use of diuretics. Schmitz¹ in 1932, after reviewing the work done on this subject up to that time, concluded that Rehberg's method of calculating the amount of filtration occurring in the glomeruli and the amount of reabsorption taking place in the tubules was satisfactory for comparing the diuretic action of theophylline ethylenediamine and salyrgan in the dog. During theophylline ethylenediamine diuresis the calculated amount of glomerular filtration was consistently increased, while tubular reabsorption showed no constant changes. Clinically, the xanthine diuretics seem to be chiefly of value in hastening the elimination of cardiac edema after digitalis and rest in bed have improved the circulation. With improvement, salt and water previously stored in the tissue spaces are brought to the kidneys for excretion. Under these conditions the increase in filtration produced by the purine derivatives is effective because reabsorption takes place to a lesser degree than normal. In other types of edema (hepatic and renal) the xanthine diuretics are of little help.

Blumgart and his co-workers² reported that there were several features in common between the xanthine and the mercurial diuretics when administered to three normal men. Their data indicate that (1) the output of water, sodium, chloride, potassium and calcium is increased after the diuretics, (2) the increases in water and in the bases—sodium, potassium and calcium—bear a constant relation to one another, (3) there is no significant change in the phosphate, sulphate ammonia or total nitrogen metabolism, (4) the increases in the excretion of water and fixed base in the urine following the various diuretics represent the loss of equivalent volumes of body fluids with their basic constituents, (5) the water and salts lost from the body of these subjects with normal water balances during the diuresis

are regained by a compensatory retention, (6) there is no significant change in the insensible loss of water or in the water or salt content of the stools, (7) in the instances reported, no significant changes were observed when repeated analyses of the blood serum for sodium chloride and specific gravity were made at intervals before, during the height of and after diuresis, and (8) measurements of the rate of glomerular filtration and tubular reabsorption according to the method of Rehberg, somewhat modified, indicate that the increased excretion of water and salts is accomplished by a relative decrease in tubular reabsorption, the rate of glomerular filtration remaining unaffected. These observers conclude, therefore, that the effect of the diuretics studied (two of each group) is qualitatively the same, the essential difference being in magnitude and duration of effect.

Salyrgan diuresis, according to Schnitz, is characterized by a considerable decrease in the percentage of fluid reabsorbed in the tubules. The amount of filtration is seldom increased significantly. The effectiveness of the mercurials in cardiac edema is therefore readily understandable. The explanation for the removal of accumulations of fluid resulting from portal obstruction and from depletion of the plasma proteins is, however, still largely speculative. In a subsequent paper, Schmitz³ reported the results of a study of the effect of salyrgan on the water content of the plasma by means of the refractometer. Evidence did not indicate that salyrgan diuresis is preceded by a mobilization of fluid from the tissue spaces. This, he believes, points strongly to a primary direct action of salyrgan on the kidney with a secondary inflow of fluid from the tissue spaces to prevent excessive dehydration of the plasma. Blumgart and his co-workers tend to corroborate this view as a result of their studies on normal individuals. In their subjects neither the mercurial nor the xanthine diuretics had an effect on the rate of glomerular filtration, but all caused an increase in the amount of urine and its constituents by a relative decrease in tubular reabsorption.

Recently Bryan and his co-workers⁴ have studied the changes in the plasma protein content after giving salyrgan, as reflected in the specific gravity, the total nitrogen content and the colloid osmotic pressure of the plasma. On edematous dogs, salyrgan produced a prolonged diuresis. Significant changes were not observed in the specific gravity, the total nitrogen content or the colloid osmotic pressure of the plasma before the onset of diuresis. Coincident with the diuresis, however, a sustained rise in all these values occurred.

The consensus therefore seems to be that both groups of diuretics exert their main action on the kidneys.

directly, the xanthine derivatives increasing glomerular filtration and the mercurials retarding tubular reabsorption. Physicians may well bear these conclusions in mind in the prescription of these remedies, either singly or in combination.

WHAT IS OSTEOPATHY?

The osteopathic practice act of Iowa, approved March 29, 1921, defined "osteopathy" as "the name of that system of healing art which places the chief emphasis on the structural integrity of the body mechanism as being the most important factor for maintaining the organism in health." That definition, rather widely adopted, seems to have the approval of many osteopaths. Presumably on the initiative of the osteopaths of Iowa, however, the general assembly of that state has now elaborated the definition. The laws of Iowa¹ now provide that

(a) Osteopathy is that school of Healing Art which teaches and practices scientific methods and modalities used in the prevention and treatment of human diseases, but whose basic concept, in contrast with all other schools, places paramount emphasis upon the normality of blood circulation and all other body functions as a necessary prerequisite to health and holds that such normality is more certain of achievement by and through manual stimulation or inhibition of the nerve mechanism controlling such functions, or by the correction of anatomical maladjustments.

(b) Osteopathic practice is that method of rehabilitating, restoring and maintaining body functions by and through manual stimulation or inhibition of nerve mechanism controlling such body functions, or by the correction of anatomical maladjustment, and/or by other therapeutic agents, methods and modalities used supplementary thereof, but such supplementary agents, methods or modalities shall be used only preliminary to, preparatory to and/or in conjunction with such manual treatment. Such osteopathic practice is hereby declared not to be the practice of medicine within the meaning of chapter 116, and is not subject to the provisions of said chapter.

Apparently the Iowa osteopaths have noticed the recent failure of the osteopaths of England to show any scientific basis for the dogma on which the osteopathic cult is founded. Presumably they are alarmed for the future of their healing cult in this country. In their new definition they have tried to show a distinction, based on scientific facts and principles, between osteopathy and other methods of healing. The result is an implication that no school or method of healing other than osteopathy "places paramount emphasis upon the normality of blood circulation and all other body functions as a necessary prerequisite to health." This is either ignorance or an attempt to fool the public and particularly the legislature and the courts.

The new Iowa osteopathic practice act admits the necessity for "therapeutic agencies, methods and modalities" other than massage and manipulation. The limitation of the use of such agencies, methods and modalities to use in conjunction with manual treatment should deceive no one. In every case in which an osteopath prescribes drugs or any form of physical therapy,

he must at some time during its course merely rub or knead the patient to an extent sufficient to constitute a compliance with the law. At the same time, incidentally he leads the patient to believe that the alleviation and cure of the disease or injury is due to the osteopathic rubbing or kneading instead of to the drugs or to physical therapy. Any competent physician would no doubt have employed these or other drugs and methods in the same case equally well or even better. Moreover, the basic education of the physician would have been greater warrant to the patient that the use of the method was for good and not for harm.

Current Comment

THE UNITED MEDICAL SERVICE, THE CIVIC MEDICAL CENTER, AND ANOTHER COMMERCIAL MEDICAL RACKET

Our readers are of course familiar with the attempt to practice medicine initiated by the corporation known as the United Medical Service, Incorporated. This organization, headed by Dr. Joseph Berkowitz, is a stock company employing physicians on salaries and marketing their wares by means of advertisements in newspapers offering medical care for various conditions at fixed prices. Some time ago a disagreement apparently arose between members of the medical staff and the corporation directorate, which resulted in both physical and mental anguish for the parties to the disagreement. As a result Chicago is now blessed or cursed with two organizations—the United Medical Service, Incorporated, which endeavors to persist at the old address, and the Civic Medical Center, which has opened up in a neighboring headquarters. The latter organization is presumably dominated by physicians but continues to exploit their services by the same type of advertisements as are used by the parent organization. Yet between parent and child there is little sympathy except for the methods of exploitation, and there seems to be but little chance that the prodigal son will ever go marching home. How well the Civic Medical Center physicians have learned the tricks of unethical practice is apparent from a recent attempt to exploit the services of one of their members by an unusual route. Not long ago newspapers in Chicago began to carry items relative to the formation of a so-called Chicago Hay Fever Club, formed, it seems, for the purpose of eliminating ragweed and making regular daily pollen counts. The treasurer of the Chicago Hay Fever Club is one Frederick B. Bassett Jr., who is at the same time advertising representative for the Civic Medical Center. The medical adviser of the Chicago Hay Fever Club, it develops, is one Dr. M. J. Steinberg, formerly a member of the staff of the United Medical Service, Incorporated, and now a member of the staff of the Civic Medical Center. The president of the Chicago Hay Fever Club is William R. Harshe, who is also publicity representative for the Civic Medical Center. Evidently the purpose of the Chicago Hay Fever Club

is to enlist the interest of the public in hay fever and to obtain a list of hay fever sufferers. Hay fever sufferers who applied to the club were promptly referred to Dr M J Stenberg, the medical adviser, without question as to whether or not they had consulted other physicians. Once physicians embark on a commercial career, such tricks and chicanery inevitably appear as concomitants of the services they render and menace the proper care of the public whose interest is elicited by their promotional devices.

DIPHTHERIA IMMUNIZATION

When diphtheria appeared recently in five widely separated sections of Washington County, Md, the county medical society appointed a committee to supervise a diphtheria prevention campaign. Practically all members of the county society participated. The committee assigned physicians in alphabetical order to city and certain county schools to work in cooperation with the county health department. The parent-teachers associations were active in securing the support of parents. After consent had been received from parents, preliminary Schick tests were given, and children having positive tests were referred to their family physicians for immunization. Those who could not afford to pay were immunized without charge. The number of Schick tests given was 9,992, and the number of doses of alum precipitated toxoid administered was 5,179. Severe reactions were rare. Two hypersensitive children developed urticaria and some edema, which disappeared within twenty-four hours. Pseudoreactions were observed in about 5 per cent of children tested in the city of Hagerstown and in about 3 per cent of children living in the rural areas. No cases of diphtheria developed among 1,998 Schick negative children, and yet three children living in the same locality who apparently had been immunized to the extent of a negative Schick test contracted clinical diphtheria after the final test was reported negative. Since the same lot of toxoid was used in giving the Schick test to all three, it seems probable that the product may have been below standard. It is also possible that the tests may have been read incorrectly. Moreover, too definite promises in regard to the amount of protection that may be expected should not be given, if diphtheria bacilli enter the body in overwhelming numbers the immunity obtained by the accepted methods may be insufficient to prevent the development of clinical diphtheria. During the year, thirty-eight cases of diphtheria developed in persons in Washington County who had had no previous immunization. Among 1,446 children between the ages of 5 and 14 whose records are complete, immunity was produced by one dose of alum precipitated toxoid in 79.8 per cent, in periods varying from eighty-six to 217 days. More than 20 per cent of children between these ages were still susceptible after one dose of toxoid. The results of this diphtheria immunization work emphasize, among other things, the importance of giving a preliminary Schick test, the necessity for giving a final Schick test in all cases, and the use of a control with each test to clarify the readings of pseudo-reactions.

Association News

RADIO BROADCASTS

The American Medical Association will broadcast over the Blue network of the National Broadcasting Company at 5 p m eastern standard time (4 o'clock central standard time, 3 o'clock mountain time) October 1 and each Tuesday thereafter, presenting a dramatized program with incidental music under the general theme of "Medical Emergencies and How They Are Met." The title of the program will be *Your Health*. The program will be recognizable by a musical salutation through which the voice of the announcer will offer a toast "Ladies and Gentlemen, Your Health!" The theme of the program will be repeated each week in the opening announcement, which informs the listener that the same medical knowledge and the same doctors that are mobilized for the meeting of grave medical emergencies are available in every community, day and night, for the promotion of the health of the people. Each program will include a brief talk dealing with the central theme of the individual broadcast.

The October schedule is as follows:

October 1	Burns, Morris Fishbein, M.D.
October 8	Hazards from Foreign Shores, W. W. Bauer, M.D.
October 15	Unconsciousness, Morris Fishbein, M.D.
October 22	Asphyxiation, W. W. Bauer, M.D.
October 29	Poisonous Plants and Insects, W. W. Bauer, M.D.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ALABAMA

A Mobile X-Ray Unit—A mobile x-ray unit was installed in Lee County recently for use in a special study of the incidence of tuberculosis in a restricted representative rural area, newspapers report. A gasoline motor-generator set on a two-wheeled trailer provides adequate 110-volt current to operate the machine. The truck, a one and one-half ton model, was specially designed and equipped to provide a complete x-ray and clinic set up, it was stated. A dark-room is built in the left front corner of the closed truck body. Portable x-ray and clinic equipment, transformer stand, cassette holder, folding tables and other equipment may be removed to allow full use of the built-in seats for twelve persons. The tuberculosis study has been in progress since May 1, 1932 and has been made possible by the Rockefeller Foundation through the state department of health.

ARIZONA

British Physicians Visit Grand Canyon—Officers of the Arizona State Medical Association and several members met the group of British physicians who recently visited the United States en route to Australia, Sunday, August 11, at the Grand Canyon. Some of the party went down Bright Angel Trail into the canyon while the remainder took a drive along the west rim. Dr Ernest Kaye Le Fleming, chairman of the council of the British Medical Association, presided at a luncheon at which the guests were greeted by Drs Charles R. K. Swetnam, Prescott president, Delamere F. Harbridge, Phoenix, secretary, and Clarence E. Yount, Prescott, treasurer of the Arizona state association. Copper letter openers bearing the seal of the society were presented to the men of the party and Indian bracelets to the women as mementoes of Arizona. In the afternoon the party was taken along the east rim of the canyon to Desert View.

ARKANSAS

Personal—Dr Andrew J. Hamilton has been appointed health officer of Rison.—Col William Lloyd Sheep has been made commanding officer of the Army-Navy General Hospital, Hot Springs National Park.

Society News—At a meeting of the Lawrence County Medical Society at Black Rock, June 11, speakers were Drs John L. Jelks, Memphis, Tenn., on "Operation for Rectal Stricture",

Joshua Harlev Harris, Memphis, "Infected Sinuses in Children and Adults," and Gus R. McClure, Paragould, "Focal Infection of Tonsils."—The Southeast Medical Society was addressed at Monticello, July 19, by Dr. Sidney C. Barrow, Shreveport, on "Radiologic Treatment in Pelvic Disorders" and "Technic for Measuring Roentgen Rays."

CONNECTICUT

List of Quarantinable Diseases Extended—The sanitary code was revised at a meeting of the Public Health Council of the Connecticut State Department of Health, July 16, to effect certain changes in the procedure dealing with communicable diseases. Under the revised code meningococcus meningitis, formerly termed cerebrospinal meningitis, epidemic encephalitis and psittacosis, will be quarantinable. Children in families in which chickenpox and mumps occur need not stay away from school until they show symptoms of the disease. This change was made because it was doubted whether the former restrictive measures have been effective in preventing these diseases. Similar modifications were made for measles and whooping cough. Septic sore throat will in the future be designated streptococcus sore throat and amebic dysentery as amebiasis. These are a part of the changes reported by the health department in its weekly bulletin.

DISTRICT OF COLUMBIA

Ophthalmologic Society Organized—The Washington Ophthalmological Society was recently organized with Drs. James N. Greear Jr. president, George Victor Simpson vice president, and Ernest Sheppard secretary. The society will hold meetings the first Monday in November, January, March and May at the Episcopal Eye, Ear and Throat Hospital. In addition to case reports, papers will be presented by out-of-town speakers and local physicians. Dr. James W. White, New York, will address the society, January 6, on eye muscles. Drs. Louis S. Greene and William Thornwall Davis, March 2, on "Treatment of Retinitis Pigmentosa" and "Treatment of Chronic Glaucoma Simplex," respectively, and May 4, Dr. Robert H. Courtney, Richmond, Va., "Uveitis with Secondary Glaucoma Accompanying Spontaneous Absorption of the Lens."

GEORGIA

Personal—The twentieth anniversary of Dr. Joseph H. Bradfield, Atlanta, as superintendent of the Battle Hill Sanatorium was observed, July 5, at an "open house."—Dr. William S. Prather, Americus, was selected as the most valuable citizen of Americus and Sumter County in a poll of citizens by the Kiwanis Club, the poll showed that Dr. Prather was favored by more than twice as many persons as any one else.—Dr. Lysander P. Holmes has been named acting superintendent of the University Hospital, Augusta, succeeding Dr. John H. Snoke, resigned.

ILLINOIS

Society News—The Henry County Medical Society was addressed by Drs. Samuel M. Feinberg and Geza De Takáts, Chicago at Geneseo, July 31, on allergy and treatment of varicose veins, respectively.—Dr. Leon Unger, Chicago, discussed hay fever before the Kiwanis Club of Harvey, July 23.

Personal—Dr. Joseph L. Bryan, Xenia, has been appointed health officer of the district including Clay, Effingham, Jasper and Crawford counties.—Dr. Hugh A. Beam, Moline, has been appointed medical director of the Rock Island County Tuberculosis Sanatorium, succeeding the late Dr. Arthur T. Leopold, effective August 1.

IOWA

Personal—Dr. Harry H. Penquite held a reception to observe his completion of twenty-five years of practice in Massena, June 15.—Dr. George Mogridge has resigned as superintendent of the State Institution for Feeble-minded Children at Glenwood, and Dr. Harold B. Dye, assistant superintendent for a number of years, has been appointed to succeed him.

Graduate Courses—Graduate instruction sponsored by the speakers bureau of the Iowa State Medical Society will be offered by districts this year, according to the state journal. The State University of Iowa College of Medicine, Iowa City, will present two of the courses and assist with the others. Thus far courses have been announced for Scott and Jasper counties. General therapeutics will be reviewed for the Scott County Medical Society, beginning about September 15 in Davenport, while the Jasper County Medical Society will have a course on cancer, beginning about the same time in Newton.

KENTUCKY

Society News—Dr. Daniel C. Elkin, Atlanta, will address the Jefferson County Medical Society, Louisville, September 16, on "Treatment of Burns."—Dr. Morris Flexner, Louisville, will address the Louisville Medico-Chirurgical Society, September 27, on "Pulmonary Moniliasis."—Dr. Fred W. Rankin, Lexington, will present a paper on "Hyperparathyroidism" before the Louisville Obstetrical and Gynecological Society, September 16.

MAINE

Personal—Dr. John A. McDonald, East Machias, has been appointed district health officer, effective June 1.—Dr. Joseph R. Ridlon, medical director of the U. S. Marine Hospital at Portland, has been transferred to the Marine Hospital at Galveston, Texas.

Society News—Speakers before the Androscoggin County Medical Society, recently, were Drs. Frank E. Barton and George Levene, Boston, on "Prevention of Intravenous Glucose Reaction" and "Value of X-Ray in the Diagnosis of Heart Disease," respectively.—At a meeting of the Hancock County Medical Society, July 25, Dr. Frederick C. Holden, New York, read a paper on "Vaginal Discharges, Their Diagnosis and Treatment."

MARYLAND

Personal—Knight Dunlap, Ph.D., professor of experimental psychology, Johns Hopkins University, Baltimore, has resigned to accept a similar position with the University of California at Los Angeles. Dr. Dunlap has been associated with Johns Hopkins since 1906, during the war he was in charge of the psychology section of the Medical Research Laboratory of the air service.

Society News—Dr. Preston A. McLendon addressed the Montgomery County Medical Society, July 16, on "Problems in the Physical and Mental Management of Infants and Children," and Drs. Herbert H. Schoenfeld and Claude Moore discussed the neurosurgical and radiologic aspects, respectively, of the diagnosis of brain conditions. All speakers are from Washington, D. C.

MASSACHUSETTS

Health Survey—The share of Massachusetts in the \$3,450,000 appropriation for a nation-wide public health survey will be \$162,000. A house to house canvass will be made to determine the prevalence of chronic diseases. Sample groups of certain income levels will be studied in this national survey, sponsored by the U. S. Public Health Service and carried out by the Works Progress Administration. Medical facilities for the care of the sick will be studied.

Personal—Dr. Charles F. McKhann, assistant professor of pediatrics and communicable diseases, Harvard Medical School, Boston has gone to China, where he will be visiting professor of pediatrics at Peiping Union Medical College during the first half of the school year 1935-1936. He will return to Boston early in March 1936.—Dr. James W. Manary has been appointed director of the Boston City Hospital to succeed the late Dr. John J. Dowling. Dr. Manary has been a member of the staff for many years.—Dr. Lawrence K. Kelley, Peabody, has been appointed superintendent of the Tewksbury State Infirmary, Tewksbury.—Dr. Joseph P. Leone, Providence, R. I., has been appointed superintendent of the Quincy City Hospital.—Dr. Albert D. Foster, medical director of the U. S. Marine Hospital, Chelsea, has been appointed to the corresponding position at the Marine Hospital at Portland, Maine.

MICHIGAN

Upper Peninsula Meeting—The Upper Peninsula Medical Society held its annual meeting at Iron Mountain, August 15-16, under the presidency of Dr. Frank G. H. Maloney, Ironwood. The following physicians participated in the program:

Fred J. Hodges, Ann Arbor, Differential Diagnosis of Lesions of the Alimentary Tract from the Standpoint of X-Ray.
Norman F. Miller, Ann Arbor, Conduct of First and Second Stages of Labor with Special Reference to Analgesia and Anesthesia.
Reginald H. Jackson, Madison, Wis., Sacro-Iliac Strain.
Grant H. Laing, Chicago, Medicinal Treatment of Peptic Ulcer.
Albert C. Furstenberg, Ann Arbor, Acute Infections of Mouth, Throat, Nose and Neck.
Howard P. Douth, Detroit, Fever Therapy.
James D. Bruce, Ann Arbor, Medical Legislation.
William H. Alexander, Iron Mountain, Injection Treatment of Hernia.
Clyde I. Allen, Detroit, Toxemia of Burns.
Gershom J. Thompson, Rochester, Minn., Diseases of the Prostate.
Fred W. Gaarde, Rochester, Minn., Allergic Disease.

Newly elected officers of the society are Drs. Edward M. Libby, Iron River, president, and Vivian H. Vandeverter, Ishpeming, vice president. The physician chosen secretary of

the Marquette County Medical Society at its annual meeting will be secretary of the peninsula medical society. The next annual meeting will be in Ishpeming.

MISSOURI

State Society Sponsors Lectures—The postgraduate committee of the Missouri State Medical Association sponsored an address before the Randolph Monroe County Medical Society at Moberly, August 13, by Dr. Edward Lee Dorscott, St. Louis, on "Internal Podalic Version." The committee also sponsored a talk by Dr. Samuel H. Snider, Kansas City, at a public meeting in Sedalia, August 15, under the auspices of the woman's auxiliary of the Pettis County Medical Society.

District Meeting—The Boone County Medical Society will be host to the Ninth Councilor District Medical Society during its annual meeting in Columbia, September 17. The meeting has been planned as "Southern Medical Association Day" in central Missouri, and the following speakers active in that association will appear on the program:

- Dr. Frank K. Boland, Atlanta, Ga., Surgical Treatment of Pulmonary Tuberculosis
- Dr. Seale Harris, Birmingham, Ala., Diagnosis and Treatment of Hyperinsulinism
- Dr. Quitman U. Newell, St. Louis, Importance of the Recognition of Early Uterine Carcinoma
- Mr. C. P. Loran, Birmingham, Some Aims of the Southern Medical Association and a Preview of the St. Louis Meeting, November 19-22

NEBRASKA

Health Service Created—The Omaha-Douglas County Central Health Service was incorporated, August 1. The new organization aims to enable persons of low income to obtain medical service at a cost within their financial means, establish a friendly doctor-patient relationship, and the physician in the collection of fees and prevent those persons from receiving free clinic care who can afford to pay for medical service. The incorporators of the new service are Dr. Frederick O. Beck, E. H. Bruening, D.D.S., and Dr. John Jay Keegan, all of Omaha. With headquarters in Omaha, the affairs of the corporation are to be conducted by a board of trustees made up of three members of the Omaha-Douglas County Medical Society, two of the Omaha District Dental Society, one member of the Omaha Hospital Council, one nurse of district 2 Nebraska State Nurses Association, and one pharmacist member of the Omaha Retail Druggists Association. Members of these organizations will also be members of the Omaha Douglas County Central Health Service.

NEVADA

Society News—Dr. Emile F. Holman, San Francisco, addressed a recent meeting of the Washoe County Medical Society on "Present Status of Surgery in the Treatment of Pulmonary Tuberculosis, Bronchiectasis and Neoplasm of the Lung."

NEW YORK

Food Poisoning in Buffalo—Eighteen cases of gastroenteritis, with two deaths, were reported to the state department of health in July. *Bacillus paratyphosus B* was isolated from specimens from one of the fatal cases and four others. The outbreak was attributed to coconut cream pie which appeared to be the only food eaten by all the persons affected but none of the food was available for analysis.

Personal—Dr. Donald W. Cohen, for seven years assistant child guidance psychiatrist of the state department of mental hygiene of the Buffalo district, has been promoted to chief child guidance psychiatrist of the department, effective August 15. He succeeds Dr. James L. Tower, Albany, who has resigned. Dr. Vernon C. Branham, Albany, deputy state commissioner of correction, has been appointed superintendent of Woodbourne Institution for Defective Delinquents, Woodbourne.

Graduate Lectures in Buffalo—The University of Buffalo School of Medicine is presenting a group of lectures for physicians during September, with the object of making available current advances in diagnosis and treatment of common diseases. The speakers are as follows:

- Col. Calvin H. Goddard, Washington, D. C., Scientific Crime Detection
- Dr. Charles R. Austrian, Baltimore, Diagnosis and Treatment of Early Tuberculosis
- Dr. Walter A. Bastedo, New York, Treatment of Constipation—Important Points in the Physiology of the Intestines and the Action of Various Drugs and Foods upon It
- Dr. Frederick F. Tisdall, Toronto, The Present Status of the Vitamins in Medicine: Their Uses and Abuses

New York City

Personal—Dr. Leslie T. Webster of the staff of the Rockefeller Institute for Medical Research has recently received a prize of 1,000 Swiss francs awarded by the Medical Faculty of the University of Berne, Switzerland, in recognition of his work on encephalitis. Dr. Webster graduated from Johns Hopkins University School of Medicine, Baltimore, in 1919 and has been with Rockefeller Institute since 1920.

Marihuana Grown on Vacant Lots—During June and July, 260 lots were cleared of 170 tons of *Cannabis sativa* plants, variously known as marihuana, hashish, bhang and loco weed in a concerted drive by the police and health departments. Samples of the plant were sent by the narcotics division of the police department to various precincts to familiarize patrolmen and detectives with its appearance. These men were instructed to report any areas in which plants resembling marihuana were found and the narcotics division then notified the department of health, which had the plants torn up by the roots by relief labor. In addition to New York City, marihuana has been found growing in the state as far north as the St. Lawrence River and as far west as Erie County, according to *Health News*.

OHIO

New Graduate Courses—The Frank E. Bunts Educational Institute, recently founded in Cleveland by relatives, friends and the Cleveland Clinic Foundation as a memorial to the late Dr. Bunts has announced its first graduate review course to be given November 11-13, on "Diagnosis and Treatment of Diseases of the Glands of Internal Secretion." The course is open to all licensed physicians and surgeons after acceptance by the registrar, only fifty applications can be accepted. Members of the staff of the Cleveland Clinic Foundation and invited guests will conduct the course. The institute was chartered last January to give graduate instruction in all branches of medicine and surgery to physicians who have graduated from approved medical schools. Application blanks and an outline of the course may be obtained from Dr. Albert D. Ruedemann, Cleveland Clinic, Cleveland. The Academy of Medicine of Lima and Allen County will offer a graduate course, September 23-27. Lecturers will be Drs. Robert F. Ridpath, Philadelphia, who will speak on otolaryngologic subjects, and Morris Edward Davis, Chicago, on obstetrics.

State Medical Meeting in Cincinnati—The eighty-ninth annual meeting of the Ohio State Medical Association will be held in Cincinnati, October 2-4, at the Netherland Plaza Hotel. Guest speakers for general sessions and section meetings will include:

- Dr. James B. Herrick, Chicago, Some Problems of Medical Diagnosis
- Dr. Frank H. Lahey, Boston, Newer Advances in Hyperthyroidism and Hyperparathyroidism
- Dr. Morris Fishbein, Chicago, Medicine and the Changing World
- Dr. Palmer Findley, Omaha, Cancer of the Cervix
- Dr. Henry F. Helmholz, Rochester, Minn., Chronic Ulcerative Colitis in Childhood
- Dr. William E. Sauer, St. Louis, Headache of Nasal Origin
- Dr. Sanford R. Gifford, Chicago, Practical Use of Bacteriology by the Ophthalmologist
- Dr. William G. Workman, U. S. Public Health Service, Washington, D. C., Status of Serums and Vaccines for the General Practitioner

Among Ohio physicians who will participate are:

- Drs. Thomas L. Ramsey and Reynold A. Tank, Toledo, Acute Monocytic (Histocytic) Leukemia
- Dr. Richard W. Finley, Cleveland, Causes for Failure in Treatment of Diabetes
- Dr. William James Gardner, Cleveland, Surgical Management of Intracranial Meningiomas
- Dr. Claude S. Beck, Cleveland, Establishment of a New Blood Supply to the Heart by Operation
- Dr. Sidney B. Conger, Akron, Laparotrachelotomies: A Clinical Appraisal
- Drs. Joseph D. Herman and Jean M. Stevenson, Cincinnati, Treatment of Abortions
- Dr. Wallace B. Taggart, Dayton, Fusospirochetal Infection of the Lung in Children
- Dr. Henry J. John, Cleveland, Relation of the Insulin Requirement to the Growth and Weight Increase in the Diabetic Child
- Dr. Carl H. Bayha, Toledo, Neurologic Complications of Acute and Chronic Mastoiditis
- Dr. Frederick F. Piercy, Youngstown, Blood Stream Infections in Otolaryngology
- Dr. Carl W. Sawyer, Marion, Menopausal Syndrome
- Dr. Frank M. Wisley, Findlay, Relation of the Practitioner to the Public Health Department
- Dr. Alfred Friedlander, Cincinnati, Professional Education in Relation to Modern Public Health

Special features of the meeting include a scientific exhibit, a golf tournament Tuesday, October 1, at the Maketewah Country Club, medical and surgical clinics at various hospitals Wednesday morning, October 2, the annual dinner, October 3, sponsored by the Cincinnati Academy of Medicine, and the organization luncheon for officers of the association and of county societies.

PENNSYLVANIA

Encephalitis at Windber—About 100 cases of "meningo-encephalitis" were reported from the town of Windber between July 21 and August 5. The cases were said to be generally mild there was one death. Dr. James P. Leake of the U. S. Public Health Service made an investigation.

State Medical Meeting at Harrisburg—The eighty-fifth annual session of the Medical Society of the State of Pennsylvania will be held in Harrisburg, September 30-October 3. Guest speakers will be

- Dr. Max Thorek, Chicago, The Rationale of Electrosurgical Obliteration of the Gallbladder
- Dr. Allen Graham, Cleveland, Cancer of the Breast
- Dr. Frederick F. Tisdall, Toronto, Prevention of Dental Caries and the Improvement of Health by Dietary Means
- Dr. Harold M. Marvin, New Haven, Conn., Anginal Heart Failure: Its Causes and Treatment
- Dr. James Alexander Miller, New York, Thoracic Surgery in the Treatment of Pulmonary Tuberculosis from the Standpoint of the Internist
- Dr. Allen O. Whipple, New York, Recent Advances in Surgery of the Pancreas
- Dr. Walter E. Dandy, Baltimore, Treatment of Injuries of the Head
- Dr. James Watson White, New York, The Screen Test and Its Modifications
- Dr. Arthur W. Proetz, St. Louis, Treatment of Sinus Disease
- Elmer V. McCollum, Ph.D., Baltimore, Recent Advances in Nutrition
- Dr. Wingate Todd, Cleveland, Clinical Significance of Skeletal Roentgen Ray Assessment in Children
- Dr. Earl D. Osborne, Buffalo, Industrial Dermatoses
- Dr. Henry G. Bugbee, New York, Cancer of the Prostate.

At the opening general meeting Tuesday morning, October 1, Dr. Alexander H. Colwell, Pittsburgh, will be installed as president and deliver his official address. Dr. Moses Behrend, Philadelphia, is the retiring president. The section on pediatrics will sponsor a dinner Tuesday evening in honor of Dr. J. P. Crozer Griffith, Philadelphia, who will discuss the history of pediatrics in Pennsylvania. The annual golf tournament will be played at the Harrisburg Country Club, Monday, September 30.

TEXAS

Personal—Dr. Philip S. Joseph, Alice, has been appointed health officer of Jim Wells County to succeed the late Dr. John S. Strickland.—Dr. Melvin L. Hutcheson, Denton, has been appointed health officer of Denton County, succeeding Dr. James H. Hicks.—Dr. Elbert W. Wright, Bowie, was recently elected chairman of the state board of health, succeeding Dr. Charles M. Rosser, Dallas.

Society News—Dr. Howard R. Dudgeon, Waco, among others, addressed the Bell County Medical Society in June on "Role of Fibrous Tissue in Disease."—Drs. Walter G. Stuck and Earl B. Ritchie, San Antonio, addressed the Cameron-Willacy Counties Medical Society, Harlingen, June 20, on "Treatment of Spinal Fractures" and "Arsphenamine Reactions," respectively.—Drs. George A. Schenewerk and Ben R. Buford, Dallas, addressed the Childress-Collingsworth-Donley-Hall Counties Medical Society, Memphis, June 22, on "Peritoneal Drainage" and "Treatment of Cardiac Edema," respectively.—At a meeting of the Wilbarger County Medical Society, June 17, Dr. Alex. B. Garland, Vernon, reported a case of rabies.—Drs. Marshall T. Knox, Jay W. Pickens and Charlie C. Jowell, Cleburne, presented a paper on obstetrics at a meeting of the Johnson County Medical Society, Cleburne, June 18.

VIRGINIA

Health at Richmond—Telegraphic reports to the U. S. Department of Commerce from eighty-six cities with a population of 37 million for the week ended August 31 indicate that the highest mortality rate (168) appeared for Richmond and that the rate for the group of cities as a whole was 9.3. The mortality rate for Richmond for the corresponding week of 1934 was 15.9 and that for the group of cities was the same as this year. The annual rate for the eighty-six cities for the thirty-five weeks of 1935 was 11.6, the same rate as for the corresponding period of last year. Caution should be used in the interpretation of these weekly figures, as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits and that Negro death rates are usually high tends to increase the death rate.

WYOMING

State Medical Election—Dr. Josef F. Replogle, Lander, was chosen president-elect of the Wyoming State Medical Society at the annual meeting in Lander in August, and Dr. Joseph L. Wicks, Evanston, was installed as president. Dr. Edwin Earl Whedon, Sheridan, was reelected secretary, and Frederick L. Beck, Cheyenne, elected treasurer. Next year's meeting will be held in Cody.

GENERAL

Prevalence of Infantile Paralysis—The number of cases of infantile paralysis in New York City reached 1,366 for the year, September 6. The number reported for the six days preceding that date was 255, compared with 358 for the previous week. In view of the decline, it was announced that schools were to open September 9. Newspapers recently announced that a laboratory was being prepared at New York University Medical College for preparation of antipoliomyelitis serum under the direction of Drs. William H. Park and Maurice Brodie of the New York City Department of Health, funds were provided by the Warm Springs Foundation. Westchester County, New York, had 110 cases, September 6.—Ten towns in New Jersey have closed their schools to prevent spread of the disease: twenty-four children were excluded from Jersey City schools because of exposure to infantile paralysis in a camp. The state health department received reports of twenty-six new cases September 5, compared with fourteen the preceding day.—Opening of public and parochial schools in Boston has been delayed until October 1, according to the *New York Times*. Massachusetts reported 408 cases during August. Boston had 204 cases from July 13 to September 3, Fall River had seventy-eight August 29.—North Carolina's health department reported only three cases for the week ended September 1, compared with eleven the previous week.

American Roentgen Ray Society—The thirty-sixth annual meeting of the American Roentgen Ray Society will be held in Atlantic City, September 24-27, with headquarters at Haddon Hall. Among speakers listed on the program are

- Dr. George E. Pfahler, Philadelphia, Malignant Lymphangitis of the Skin Mistaken for Radiodermatitis
- Dr. Charles L. Martin, Dallas, Texas, Relation of the Endocrine System to Malignancy
- Dr. Barton R. Young, Philadelphia, Liver Extract as a Specific Remedy for Roentgen Sickness
- Dr. Kenneth S. Davis, Los Angeles, Blood Vessel Markings in the Dorsal Vertebrae Simulating Fracture
- Dr. Ralph K. Chormley, Rochester, Minn., Study of the Synovial Membranes in Various Types of Arthritis by Differential Stains
- Dr. Henri Coutard, Paris, Present Additional Treatment with Roentgen Rays in Carcinoma of the Cervix and Protracted Roentgen Therapy of the Pelvis
- Drs. Elizabeth K. Rose, Ardmore, Pa., and David Stewart Polk, Rosemont, Pa., Late Effects of Thymus Irradiation
- Dr. Sherwood Moore, St. Louis, Roentgenographic Studies of a New Metabolic Disease
- Dr. Coleman B. Rubin, New York, Roentgen Criteria for the Operability of Lung Tumors
- Dr. Fred J. Hodges, Ann Arbor, Mich., Value of Oral Examinations and the Correlation of Variation in Density with Actual Pathology as Revealed by Operative Tissue Material in 2,000 Gallbladder Cases

There will be symposiums on lymphoblastoma and on research work on the small intestine, and Dr. John Shelton Horsley, Richmond, Va., will deliver the Caldwell lecture.

Meeting of Academy of Ophthalmology and Otolaryngology—The fortieth annual session of the American Academy of Ophthalmology and Otolaryngology will be held in Cincinnati, September 15-20, under the presidency of Dr. Wells P. Eagleton, Newark, N. J. The meeting will open with a joint session of the sections at which Dr. Hans Brunner, Vienna, Austria, will deliver an address on brain tumor and the ear, and a symposium on headache will be presented by Drs. Harris H. Vail and Alphonse R. Vonderahe, Cincinnati, and William H. Crisp, Denver. Separate section meetings will be held in the afternoons with the following speakers, among others:

- Dr. Algernon B. Reese, New York, Massive Retinal Fibrosis in Children
- Dr. Harry W. Woodruff, Joliet, Ill., Management of Complications in Surgery of Senile Cataract
- Dr. Warren T. Vaughan, Richmond, Va., Allergy in the Rhinologist's Waiting Room
- Dr. Lyman H. Helne, Boston, Effect of Radiation on Ciliated Epithelium
- Drs. Samuel Salinger and Samuel J. Pearlman, Chicago, Malignancies of the Epipharynx
- Dr. Wendell L. Hughes, Hempstead, L. I., N. Y., Aniseikonia: Some Clinical Applications
- Louis A. Julianelle, Ph.D., and Roland W. Harrison, Ph.D., St. Louis, Studies on the Infectivity of Trachoma
- Dr. Dean M. Lierle, Iowa City, Focal Infection in Arthritis
- Dr. Moses H. Lurie, Boston, Animal Experimentation on Hearing—Its Clues to the Prevention of Deafness
- Dr. Gabriel Tucker, Philadelphia, Chronic Inflammatory Lesions of the True Vocal Cords

Tuesday, Wednesday and Thursday mornings will be devoted to instructional courses. Friday morning members of the academy will be guests of the Cincinnati General Hospital at clinics and demonstrations and Friday afternoon a golf tournament will be held at the Cincinnati Country Club. Thursday evening there will be a special meeting devoted to discussion of medical economics, with Dr. Rosco G. Leland, director of the Bureau of Medical Economics of the American Medical Association, Chicago, as the speaker. At the annual banquet

Wednesday evening, Dr Max A Goldstein, St Louis, oldest living past president of the academy, will review the history of the organization and Dr Frank E Burch, St Paul, will be installed as president

Government Services

Public Health Surveys

Nine cities and nineteen states have been selected by the U S Public Health Service for its survey of health conditions with special reference to chronic diseases and physical impairments. The cities announced were Birmingham, Chicago, Baltimore, Detroit, St. Louis, Trenton, New York, Dallas and Richmond, and the states Massachusetts, New York, New Jersey, Maryland, Virginia, Pennsylvania, Ohio, Georgia, Alabama, Louisiana, Texas, Minnesota, Michigan, Illinois, Missouri, Utah, California, Washington and Oregon. About 6000 men and women now on relief rolls will be employed for the survey of 750,000 families. Financed by a fund of \$3,450,000, work on the project will commence about October 15 (THE JOURNAL, July 13, p 129)

Annual Training Course for Medical Reserves

The seventh annual training course for medical department reserves of the U S Army and Navy will be held at the Mayo Clinic, Rochester, Minn., October 6-20. Morning hours will be devoted to professional work in special clinics, and study groups and the afternoons and evenings will be given over to medicomilitary subjects. Officers in attendance may select the course they wish to follow from the wide variety of presentations offered. The staff and faculty of the Mayo Clinic will present the professional training, while the medicomilitary program will be under the direction of the surgeon of the seventh corps area (army) and the surgeon of the ninth naval district (navy), to whom all applications should be submitted. Enrollment, which is limited to 200, is open to all army and navy reservists of medical departments in good standing.

Health of the Army in 1934

A preliminary report on the health of the army in 1934, compiled from weekly statistical reports, shows that the death rate for the whole army was 378 per thousand of strength. Of 511 deaths, 265 were caused by diseases and 246 by injuries. The general admission rate was 624 per thousand, which is comparatively low, it was said. Respiratory diseases accounted for more admissions than any other group, a rate of 136. The highest rate occurred in Panama, 208. The pneumonia rate was highest in Hawaii, 3 per thousand, almost twice as high as that for troops in the United States. The highest rate for influenza was reported from troops stationed in China. In the entire army there were 9 cases of meningitis, 12 diphtheria, 649 measles, 245 mumps and 43 scarlet fever. The incidence of malaria was 66 per thousand, and nearly half these occurred in Panama. The venereal disease rate was 29, the lowest on record. In the Civilian Conservation Corps the general admission rate for the year was 1,256, 974 for diseases and 282 for injuries. There were 871 deaths, 445 caused by disease and 426 by injuries, the death rate was 284.

Committee to Coordinate Health Activities of Government

The creation of an interdepartmental committee to coordinate health and related welfare activities of the federal government was announced by President Roosevelt, August 15. In a statement to the press, the President said:

In view of the passage and signing of the Social Security Bill there is increasing necessity for better coordination of the health activities of the Federal Government. I am therefore creating at this time an interdepartmental committee to give attention to this subject. As members of this committee I have appointed the following government officials: Josephine Roche, Assistant Secretary of the Treasury; Chairman Oscar Chapman, Assistant Secretary of the Interior; M. L. Wilson, Assistant Secretary of Agriculture; and A. J. Altmeyer, Second Assistant Secretary of Labor.

I am directing this Committee to include within the scope of its work not only health activities but closely related welfare activities as well. As its immediate task I am instructing this Committee to assume responsibility for the appointment of special committees to be composed of physicians and other technically trained persons within the government service to study and make recommendations concerning specific aspects of the government's health activities. I am confident that this procedure will facilitate the consummation of a series of appropriate cooperative agreements between the various departments of the government. I am also hopeful that in this way we can eventually bring about a complete coordination of the government's activities in the health field.

A Veterinary Centenarian and Discoverer

Dr Griffith Evans of Bangor, North Wales, attained his hundredth birthday, August 7. While in the army veterinary corps in India he discovered the trypanosome of surra, a disease of horses, camels and cattle. In 1885 this protozoon was named *Trypanosoma Evansi*. He thus laid the foundation of protozoon pathology, in which the next discoverer was Bruce, who in 1894 found that tsetse fly disease of animals was due to another trypanosome (*Trypanosoma Brucei*). In 1903 he and Nabarro found that the tsetse fly also was the carrier of trypanosomiasis. In a letter to the *Times*, Dr Ivor J Davies of Cardiff recalls a visit of Osler to that town. He asked, "Where does Griffith Evans live?" A reply not having been forthcoming he said "What! Don't you know the man who first saw a pathogenic trypanosome?" On his birthday Dr Evans received in his bedroom a telegram of congratulation from the king and queen at the moment when Sir Frederick Hobday, principal of the Royal Veterinary College, presented a scroll stating that it is proposed to set up in the college a plaque recording the fact that Dr Evans, the father of the veterinary profession, consented to lead the endowment movement. Dr Evans replied from his bed, to which he is confined by an accident, in a voice that could be heard outside the house. He discoursed for half an hour on scientific problems and mentioned that in his college days no microscopes were provided for students.

Women Orderlies in the London County Council Hospitals

The London County Council controls the greatest hospital system in the world, consisting of 30,000 beds. The proposals of the Hospitals and Medical Services Committee for twelve of the general hospitals for acute diseases are of much interest. These hospitals are recognized as training schools for nurses. The committee holds that the employment of women orderlies in addition to or in substitution for a proportion of the probationer or assistant nurses is desirable. The results of the council's nursing examinations show that the training of the probationers needs to be strengthened on the practical side. During their first year of training they are so occupied in routine cleaning duties that they are unable to give the requisite time and concentration to the elementary nursing duties. When the council recently took over hospitals which were until then under the control of the local authorities they found that in two, twenty-five female orderlies were employed. Experience with their work indicates that their employment at other hospitals would be an advantage.

These proposals emanate from the socialist party now controlling the council. It was opposed by Dr Barrie Lambert, a woman physician who was chairman of the committee before the socialists came into power. She said that many of the duties to be entrusted to the orderlies are highly important to the training of a nurse. To employ untrained women on work that should be done by a probationer, under the supervision of or in company with a nurse, would lower the standard. One of the proposals is that the orderlies should assist in blanket-bathing, dressing, moving or making the bed of a patient, for which two persons are required simultaneously. These are patients gravely ill who require the attention of trained workers and in the care of whom valuable instruction should be given to probationers by the seniors. Also the proposal would unnecessarily increase the staff employed at the

twelve hospitals from 2,348 to 2,634 and involve an extra expenditure of \$410,000 annually. The latter consideration had no weight with the socialist majority of the council and the proposals were adopted.

Handbooks on Air Raid Precautions

An official handbook on precautions against gas attacks in air raids has been issued by the government. It is intended primarily for the assistance of ambulance and other workers serving the civil population, but it also contains much advice for the public, which is told that casualties will be reduced by observing the following rules: 1 If caught in the open during an air raid, seek the nearest available cover and do not leave until the "all clear" signal is given. 2 Select a suitable room in your own home and another in your place of business and have these rooms gas protected. 3 If you have a respirator, make sure that it is in a readily accessible place. Among the precautions to be taken when it is necessary to enter a gas contaminated area is the following: "Whenever gas can be detected by the sense of smell or by the effect on the eyes or throat, and whenever it is necessary to pass down-wind of craters which have been marked as dangerous from gas, the respirator must always be worn and not be removed until the wearer has assured himself that no gas is present by inserting the fingers between the face piece and the cheek and sniffing gently." On the subject of selecting a room for gas protection, the following recommendations are made: 1 A cellar or basement is the best. ("If there is no basement, choose a first floor room if there is another room above it, but in a two story house choose the ground floor.") 3 The windows of the room should be small and if possible not in an exposed position. The glass will be liable to be broken by high-explosive bombs, even at a distance, and some other covering will have to be fastened on the window frame. 4 Where possible the room should be on the side of the house least exposed to the prevailing wind. 5 The entry of gas into a house is always assisted by draughts so shut all doors and windows before retiring to the gas protected room.

CONTAMINATED CLOTHING

For those who have to work in gas-filled streets, special oil-skin clothing is recommended, with rubber boots and respirator, but for those caught in an attack of mustard gas the contaminated garments should be removed as quickly as possible and a bath taken. If this is done within twenty minutes serious injury may be avoided. The risk will be reduced if contaminated outer garments are removed immediately. In the majority of cases contaminated persons cannot return to their homes within twenty minutes, and therefore public decontamination centers will be required. Where ordinary clothing has been subject only to contamination with vapor, it may be sufficient to hang the outer clothing in the air for twenty-four hours and to wash light dresses and underclothing in soap and water for at least fifteen minutes. Liquid contamination of outer clothing must be treated in a steam disinfectant and underclothing boiled for at least an hour.

Five other handbooks on air raid precautions are being prepared.

The Museum of the Royal College of Surgeons

The annual report of the conservator of the Museum of the Royal College of Surgeons announces a policy which, it is hoped, will render the collections more attractive and instructive. For some years the growth of the Anatomical Series has been tardy and not commensurate with its practical importance. Arrangements have been made for a more liberal and constant supply of material, and as this becomes available new regional and systematic dissections will be made. An extension of the surgical anatomy is proposed so as to illustrate by actual dissections the several surgical approaches to different regions

and structures. But so ambitious a scheme, with its enormous demands on time, skill and material, is at present impracticable. It will require the cooperation of surgeons familiar with the difficulties and details of the several operative measures.

In regard to pathologic specimens the rule has been laid down that in future no specimen will find its way to the shelves unless it illustrates satisfactorily a clinical condition; i. e., the exhibit must be a first class pathologic specimen with complete record of the clinical history. Too many of the present specimens lack a clinical history and in consequence must be regarded only as pathologic curiosities. The catalogue will contain not only a brief description of the specimen and its clinical history but also a brief outline of its characteristics on microscopic examination. When necessary, photographs of the patient and small reproductions of roentgenograms will be included.

Apropos of Social Insurance, Where Are We Going?

Massart, in the July 28 issue of the *Concours médical*, states that the question Apropos of social insurance, where are we going? is one to which every French physician concerned about his future has been giving earnest consideration during the past ten years. No matter how optimistic one may be, it is difficult to see the future for the profession except as a dark picture in which medicine will be a state affair, with the tacit consent perhaps of many who only aspire to have a sure income as state officials. There is an astonishing lack of interest in fighting the battle against state medicine. "Whither are our social laws leading us?" Toward free medicine. The French medical profession is a divided house split into several parties and this condition becomes worse every day. The state is profiting by this internal strife and only awaits the day when the profession will be the victims. The profession in France is organized into unions called "syndicats" and there is constant friction between the societies. During the early years of the social insurance law there was loyal cooperation between the profession represented by the "syndicats," and the primary collecting and disbursing agencies (caisses) of the social insurance organization. The profession made all sorts of sacrifices in order to adapt its traditions to the law's requirements. In certain departments of France the law has been modified, with the consent of both parties, in order to render its application practicable.

When one keeps in mind the difference between city and country practice, it is not surprising to find that some physicians are favored and hence contented while others are disgruntled. But the favorites of today will be tomorrow's victims, as one can observe, now that the law is in force, because the "caisses" have less money at their disposal and some are threatened with insolvency and hence try to cut down the costs of medical care to the minimum.

The social insurance authorities find that it costs too much to have an insured worker cared for in a hospital that has not made an arrangement for such care, and hence the authorities are trying to force the assured to make up the difference if they choose to enter a hospital that does not have special rates for the insured. The law as originally conceived did not take this extra expense into consideration. It was assumed that hospital care would not cost more than care at home. The question now presents itself as to who will pay the difference between the two types of care.

The social insurance law has made so many demands on the medical profession since 1930 that the latter has become the servant of those who administer the law. This cannot end otherwise, according to Massart, than to make government officials of all medical men. They will then be sure of an

adequate income and of a pension on retirement. On the other hand, the profession must become more strongly organized than it is at present and will then, like similar organizations of government officials, be able to look after its interests better than it can at present.

Celebration of Fifty Years of Antirabic Vaccination

The first vaccination against rabies was administered by Pasteur in 1885. In commemoration of this important date, a meeting took place July 6 at the Pasteur Institute of Paris. A number of representatives of the institute, university and ministry of public health and education were present, including Pasteur Vallery-Radot, the grandson of Pasteur. Louis Martin, director of the institute, reviewed the career of Pasteur from the time when he began the treatment of anthrax to that of the vaccination against rabies. The communication made by Pasteur on the latter before the Academy of Sciences was read by Pasteur Vallery-Radot. Pierre Lepine reported the number of cases treated during the past half century. An honorary medal was given by the minister of public health to Jules Vialat, the oldest research worker at the institute and to Joseph Meister, who was the first person vaccinated by Pasteur and is still a janitor at the institute. Wreaths were placed on the tomb of Prof. Emile Roux at the close of the ceremony and the crypt in which Pasteur is buried was visited.

Professional Secrecy and Social Insurance

A question has arisen as to whether a physician treating an insured worker is obliged to divulge the nature of a malady. The subdirector of the Caisse, or pay office, for two large departments, Seine, in which Paris is situated, and Seine et Oise, adjacent to it issued an order according to which medical inspectors could require certificates to be issued at the residence of the insured sick person showing the diagnosis and nature of the treatment given by the attending physician. An appeal was taken from this ruling and a committee of the Academy of Medicine asked to give its opinion. This committee finds that the insured have the right to ask for professional secrecy regarding their ailments. Information regarding the character of the disease and the treatment given can be given only in professional secrecy to the medical inspectors of the social insurance offices.

First Aid Stations on Highways

The International League of Red Cross Societies has its headquarters in Paris. The general secretary, Mr. Ernest Swift, is making every effort to encourage the establishment of first aid stations on all automobile routes. In England, France and Hungary, considerable progress has been made in this direction. The movement in France began in 1926 and became nation wide under the direction of the French touring club three years later. The creation of an international permanent commission for first aid on highways was decided on in 1930. Plans have been prepared toward the standardization of this work all over the world.

The fifteenth International Red Cross Conference held in Tokyo in 1934, passed a resolution expressing the hope that each national Red Cross Society will give special attention to the development of effective and uniform facilities for rendering first aid on highways, in close cooperation with national touring associations and automobile clubs. A conference was held in May 1935 at Budapest, at which reports of the organization of first aid on highways was made by representatives of the Red Cross of eighteen countries. One of the speakers advocated the preparation of a film that would demonstrate the ten rules to prevent accidents and also the broadcasting of these rules at intervals. Representatives of the Netherlands, Sweden, Hungary, Great Britain and France cited the progress made in their respective countries in organizing this first aid

Assistance to Abnormal Children

In one of the recent issues of the *Revue médico-sociale de l'enfance*, Dr. G. Heuyer stated that twenty years ago it was difficult to interest public opinion in France in abnormal children. Now it is realized that on the amount of attention given to abnormal children depends the prevention of crime and mental disease in the adult.

Many private institutions have sprung up, organized by persons quite unfit to take charge of and educate the abnormal child institutions not under any control of the state, in which children have suffered from neglect.

In the discovery and treatment of abnormal children there is not sufficient cooperation between the physician and the instructor, only if these two work together can good results be obtained.

There is no proper classification of cases, and in every institution one will find together all degrees of mental deficiency, from the undeveloped child to the incorrigible delinquent and the incorrigible pervers. It is necessary now to organize these institutions so that each establishment may receive a special type of abnormal children.

For the discovery of abnormal children there should be infantile neuropsychiatric clinics in every large city, where the school directors, medical inspectors and social workers cooperate.

The law of 1909 provides for medicopedagogic commissions but these are still nonexistent. The abnormal children from each school should be brought before these commissions and it is for them to decide to which center of special treatment and teaching each child should be sent.

The children would be divided into several classes.

A The undeveloped, who are divided again into the backward children susceptible of some education and those not susceptible of being educated but still capable of some manual labor.

B The unstable, the very unbalanced and vicious.

1 The unstable turbulent children, runaways, tramps and thieves in embryo, are often intelligent and need treatment and discipline. They should be educated and taught a profession.

2 The highly unbalanced and vicious should be sent to isolated institutions of reeducation or those annexed to psychopathic hospitals.

C There should be special centers for the epileptic and the encephalitic, organized along the same lines as the Franklin school at Philadelphia.

Briefly, each individual as discovered should be directed to an institution especially suited to the mental and bodily condition of the child. A law should be passed that when he becomes an adult he should still be under guardianship.

Death of Prof. Robert Proust

One of the leading surgeons of Paris, Prof. Robert Proust, aged 62, died in June of a cardiac ailment. He had just been appointed to the chair of gynecology in the Faculté de médecine. Proust was the assistant to Pozzi for ten years and after successive promotions became chief of the surgical service in the large public hospitals of Paris. He was elected secretary-general in 1930 of the Société de chirurgie and took an active part in the meetings of this important organization as well as in those of the International Surgical Society of which he was a delegate for France.

He was one of the first in France to study the technic of hypophysectomy. Early in his career he wrote a number of papers on urologic subjects, especially perineal prostatectomy. Later he became interested in cancer of the cervix uteri, plastic operation for prolapse and other gynecologic subjects. During his service at the Laennec Hospital, in association with Maurer, Leon Bernard and Rist, he developed the surgical treatment of pulmonary tuberculosis.

Aside from his skill as a surgeon, his knowledge of general literature was admired by those with whom he came in contact. The two brothers, Marcel Proust the author and Robert Proust the surgeon, were prominent figures in modern French literary and medical circles.

Epidemics in Germany in the Past Century

Dr. Dornedden, "regierungsrat" in the federal bureau of health, has prepared a summary of the history of epidemics in Germany during the past century, which reveals the progress that has been made during that period in the combating of epidemics. The tabulation shows the deaths per thousand during, for the most part, five and ten year periods since 1850.

1851-1860	26	1901-1910	19
1861-1870	27	1911-1913	16
1871-1880	27	1921-1925	13
1881-1890	25	1926-1930	12
1891-1900	22	1931-1933	11

The tremendous decline in the mortality rate is due in part to a shifting in the structure of the population but chiefly to the great progress that has been made in the methods of combating epidemics. Evidence of this progress lies in the fact that around 1875 the average span of life was thirty-seven years but by 1925 had risen to about fifty-seven years and is now more than sixty years. It has become possible practically to exclude plague, yellow fever, cholera, typhus, leprosy and smallpox.

During the period 1816-1874, cholera (which first appeared in Prussia in 1831) and smallpox caused 379,582 and 165,997 deaths, respectively. Of these deaths, 149,370 resulted from cholera and 100,350 from smallpox during the period 1861-1874. In 1866 the mortality from cholera rose to 59 per 10,000 of population, while in 1872 the mortality from smallpox reached 264. For the sake of comparison, it may be stated that the last great epidemic in Germany (that of influenza in 1918) caused 293 deaths per 10,000 of population. Since cholera in 1892 claimed about 9,000 victims in Germany, epidemic diseases (aside from about 2,000 cholera, 2,700 typhus and 1,700 smallpox deaths during the recent war and early postwar period) have appeared only in small areas. During the last ten years (1925-1934) there have been no cases of cholera, yellow fever or plague, while there have been only twenty-one cases of typhus, twenty-eight of leprosy and forty-four of smallpox, which resulted in sixteen deaths from these three diseases. As a result of constant contacts at the frontiers, sporadic cases of these three diseases occurring in Germany have shown that they constitute a continuous menace that the government must take account of, for it is due only to the progress of bacteriologic knowledge that they have been so successfully combated.

The crusade against puerperal fever has likewise been strikingly successful. During the period 1816-1874, 314,579 deaths from this disease were recorded in Prussia, or 842 deaths per 10,000 confinements, and for the period 1871-1874 there were 88 deaths per 10,000 confinements. During the short period from 1874 to 1892, the mortality was brought down to 185 and by 1902 to 147. The fact that afterward, by 1922, the mortality had risen to 275 and in 1923 to 288, and by 1932 had been reduced only to 247, was due to the increase in the number of abortions, in which of course the necessary precautions were not always observed.

The deaths from children's diseases, such as measles, scarlet fever, whooping cough and diphtheria, also show a marked decrease. This was due in part to the decline in the birth rate and the resulting reduction in the percentage of children in the population. It may be stated, however, that the decrease in mortality was observable much earlier than the decline in the birth rate. Also the fluctuations, which are observable in many

epidemics without any apparent cause, play a considerable part in the infectious diseases of childhood, particularly in diphtheria and scarlet fever. Almost 14 per cent of all deaths in Prussia in 1886 were caused by these children's diseases, whereas in 1932 only 1.2 per cent of the deaths in the German reich were due to these causes.

The circumstances that helped to reduce the incidence of children's diseases have had no influence on the marked decline in tuberculosis mortality. In 1876 the tuberculosis mortality in Prussia was 318 per 10,000 of population. In 1886 incomplete statistics placed the mortality at 311, while in 1892 the mortality had dropped to 250 in Prussia and to 259 in the German reich, where in 1912 a further decline to 15.3 and in 1932 to 7.6 was recorded. It may be seen, therefore, that the present mortality from tuberculosis in Germany is only 29.3 per cent of that recorded for 1892. In 1876 the deaths from tuberculosis constituted more than 12 per cent of the deaths from all causes, whereas in 1932 the percentage had been reduced to less than 7.

Typhoid and dysentery as causes of death have been successfully combated. In 1876 the mortality from typhoid and dysentery in Prussia was 81 per 10,000 of population, whereas by 1892 the mortality rate had steadily declined to 24 for Prussia and to 18 for the German reich, where it dropped to 01 for the year 1932.

Fifty years ago, more than a fourth of all deaths were due to the epidemics mentioned, whereas in 1932 less than 9 per cent of the total number of deaths were due to these causes.

Certain animal diseases that are seldom transmitted to man, such as rabies, anthrax, glanders and trichinosis, caused thirty-six deaths in Germany in 1892, thirty-nine in 1902, forty-eight in 1912, forty-eight in 1922 and nine in 1932. It is evident that the number of victims did not decline until during the postwar period. At present, of the epidemic diseases, tuberculosis deserves the greatest attention, next come influenza and diphtheria. Of the transmissible diseases that are less frequently fatal, the venereal diseases are the most important.

Children in German Families

For the first time the general census of 1933 collected information in regard to the fertility of the German family by recording the number of children belonging to married couples living in wedlock. The important factor of the duration of the recorded marriages was omitted.

It was found that 18.9 per cent of the existing marriages were childless, 23.2 per cent had produced one child, 19.8 per cent two children, and barely 40 per cent three or more children. The fertility of the marriages in the principal social groups varied greatly. To what extent, however, this can be explained by the average length of the married life, and how great the differentiation in the willingness to have children may be are not yet fully established. The largest number of children was found among peasants, agriculturists and agricultural laborers, the lowest number among employees in industry, trade and public services, including civil functionaries.

Responsibility in the Management of Private Hospitals

The relations of the owners of German private hospitals to their directing physicians have been fixed by an agreement entered into by the chief of police of Berlin, the "chamber of physicians," and the federal league of the private hospitals. The following points covered by the agreement may be emphasized. All the equipment of the institution, to the extent that it concerns medicine and hygiene, is under the supervision of the directing physician. The latter is responsible to the board of trustees for the observance of all regulations. The engagement and the dismissal of assistant physicians and interns must be left entirely to him. The employment and dismissal of the care-taking personnel also rest with the medical superintendent. He can demand also the dismissal of aids and other personnel.

in case there are important reasons for such action. In medical matters he has also the supervision of the physicians and the personnel, but not in economic matters. He is entitled to an annual vacation of four weeks without deductions from his salary. The owner of the institution must engage the *locum tenens* and pay all the incidental expenses. The superintendent must accept the *locum tenens* engaged by the owner of the institution. The same rule applies in the event that a *locum tenens* must be appointed by reason of the illness of the superintendent. After the lapse of six weeks, the superintendent's salary may be used, in whole or in part, in compensation of the *locum tenens*. Unsettled controversies must be left to arbitration. The Berlin "chamber of physicians" makes the conclusion of such contracts compulsory for all physicians serving as medical superintendents in private hospitals. Before such contracts are signed they must be submitted to the "contract committee" of the chamber of physicians for approval.

ITALY

June 15 1935

Discussion of Coronary Lesions

The first Italian Cardiologic Congress was held recently in Milan. Professor Cesaris of Demel discussed the relations between the anatomic changes in the coronary arteries and the cardiac syndromes. The changes that affect the coronary arteries are usually of a degenerative or inflammatory nature. He discussed particularly the atherosclerotic process which may affect the coronaries throughout or may be localized at the outset in the first portion of the aorta, where it originates and then extend farther. Obstruction or occlusion of the small terminal branches may follow. The influence on the state of nutrition of the myocardium is variable according to the location of the anastomoses and the different degree of involvement of these vessels. The ischemic area, however, is always less than the distribution area of the vessel; the resistance of the myocardium depends also on the conditions preceding the ischemia. Syphilitic lesions are localized in the first part of the aorta, whence they spread to the coronaries. The tropism of syphilitic infection for the aorta is shown by the histologic examination of cases of syphilitic mesarteritis. Around the vasa vasorum of the aorta appear infiltrates that are lacking about the vasa vasorum of the pulmonary artery, although these are located close to the former and although irrigated by the same blood charged with spirochetes. In syphilis there is an endarteritis that leads to occlusion. Occasionally emboli are observed, resulting in obstruction of the large branches of the coronaries. These phenomena are always grave, owing to the rapidity with which the blood circulation is interrupted. In case of rapid occlusion of the coronaries there is an extensive myocardial infarct, with characteristic electrocardiographic symptoms.

Senator Pende and the Accademia Mediterranea

Prof Nicola Pende, senator medical clinician of the University of Genoa, has been appointed an honorary member of the Accademia Mediterranea, the headquarters of which are in the principality of Monaco. In presenting him to the academy, Dr Faure recalled the researches of Professor Pende on the racial types still distinguishable in Liguria, which in their profiles (Liguroid and Cro Magnoid) bear a resemblance to the founders of the first Mediterranean civilization. In his reply, Senator Pende pointed out that his studies led him to believe there is a close relation between the racial characteristics of man and the deeper psychology which is quite different from the social psychology of the individual. The study of Professor Pende on the racial types occurring among the Mediterranean peoples reveals that the three brown races—Mediterranean

Adriatic and Alpine—make up, in varying proportions, each of the peoples that have lived during the past thousands of years in the Mediterranean basin, and that there is a marked biologic and psychologic affinity between them.

A New Department in the Institute of Public Health

A special department of epidemiology and prophylaxis has been opened in the Istituto di sanità pubblica and has taken over the study and control of the sanitary conditions and the demographic changes taking place in the country, especially as regards the causes of epidemics. To stimulate the collection of sanitary data of interest to the public health service, the minister of the interior has sent a circular letter to the prefects of the realm, in which certain norms and standard forms are established. The notification of infectious diseases, long since compulsory, has been made more stringent, particularly as regards poliomyelitis and epidemic encephalitis. The notification should contain details of every single case. The attending physician should send his report to the "provincial physician," who, after examination and adjustment, will send it on to the epidemiologic department of the Istituto di sanità. To this body will be sent weekly and monthly bulletins concerning the sanitary condition of the communes with regard to infectious diseases, individual bulletins on venereal disease and annual reports on the functioning of the ambulatoriums established to combat trachoma and venereal diseases, including syphilis. Compilations must be made also of smallpox vaccinations and revaccinations performed in the various communes, and data must be furnished pertaining to the demographic changes occurring each month in the chief towns of the provinces and in the more important communes, and with regard to the activities and the mortality in the *gouttes de lait*.

Defense of Ophthalmologic Practice

The ophthalmologists of Milan, following the example of their colleagues in Rome and Palermo, met recently to decide on what defensive measures they should take to prevent encroachments on the practice of their specialty. It was reaffirmed that the testing of vision is an act essentially medical and that opticians may manufacture and sell lenses and spectacles only on medical prescription. The presence of certain so-called specialists in the shops of opticians is offensive to the dignity of the medical profession and such practice should be prohibited, just as physicians are prohibited from acting as pharmacists. It was proposed that the present laws pertaining to the auxiliary trades of the medical profession be modified in the sense stated.

Marriages

FRANCIS M. THIGPEN JR., Philadelphia, to Miss Nancy Burgoyne Stack of Alexandria, La., July 25

EDWARD CANIPELLI, Macon, Ga. to Miss Dorris Violet Ott of Sandusky, Ohio at Cincinnati, August 10

RICHARD BASCOMB WARRINER JR., Atlanta, Ga. to Miss Ellen Lowry Hayes in Decatur, June 24

FRANKLIN HAYWARD GRAUER, New York, to Miss Katherine Hartley Craycroft of Baltimore, July 5

WILLIAM E. NEFF JR., Waterbury, Conn. to Miss Philomena Sylvia of New Bedford, Mass. July 27

WALTER ROBERT WEGNER to Miss Margaret Irene Clarke, both of Boston, June 29

ABRAHAM GOLDFARB, Rutherford, N. J., to Miss Ruth Rinzler of Passaic, August 18

WALTER PRUSAIT, Chicago, to Miss Leona Schupmann of St. Louis, July 25

BEVERLEY C. COMPTON, Baltimore, to Miss Cynthia Wilson of Chicago, recently

DEATHS

Deaths

Barton Cooke Hirst * professor of obstetrics at the University of Pennsylvania Graduate School of Medicine, and since 1927 emeritus professor of obstetrics at the University of Pennsylvania School of Medicine, died, September 2, at his home in Philadelphia. Dr Hirst was born in Philadelphia, July 20, 1861. He received his doctor of medicine degree from the University of Pennsylvania Department of Medicine, Philadelphia, in 1883, and then studied at the universities of Heidelberg, Vienna and Berlin, later serving an internship at the Royal University Hospital in Munich. In 1889 he became professor of obstetrics at his alma mater and served in that capacity for thirty-eight years. He built a three bed hospital at the university to enable his students to supplement their knowledge gained from lectures with practical experience in the operating room. In 1908 he founded a dispensary for clinical demonstrations. He was chairman of the Section on Obstetrics, Gynecology and Abdominal Surgery of the American Medical Association, 1932-1933. Dr Hirst was a fellow and one of the founders of the American College of Surgeons. He was a former president of the American Gynecological Society and the American Obstetrical Society, a corresponding member of the Society of Obstetrics and Gynecology of Paris a consulting surgeon of the Paris Society of Foreign Surgeons, an honorary member of the Obstetrical Society of Edinburgh and an honorary foreign member of the Belgian Gynecological and Obstetrical Society. At various times he was on the staffs of the Philadelphia Orthopedic Hospital and Infirmary, Philadelphia Hospital, Philadelphia Lying-in Charity Hospital and the Preston Retreat Hospital, Pottstown (Pa.) Hospital and the Newport (R. I.) Hospital. Dr Hirst received the honorary degree of doctor of laws from the University of Pittsburgh and that of doctor of science from the University of Pennsylvania. He was the editor of "A System of Obstetrics," and author of "A Textbook of Obstetrics," "Atlas of Operative Gynecology" and other textbooks on obstetrics and diseases of women.

John William Keefe, Providence R. I., University of City of New York Medical Department, 1884, in 1914 member of the House of Delegates of the American Medical Association, member and president, 1913-1914, of the Rhode Island Medical Society, president of the American Association of Obstetricians and Abdominal Surgeons, 1916-1917, member and president, 1924-1925, of the New England Surgical Society, member of the New England Obstetrical and Gynecological Society and the American College of Surgeons, served during the World War, at various times on the staffs of the John W. Keefe Surgery, the Rhode Island Hospital, St. Joseph's Hospital, Providence City Hospital and the Lyng-in Hospital, Providence, the Memorial Hospital, Pawtucket, and the South (R. I.) Hospital, the Westerly (R. I.) Hospital, died suddenly August 4, at his summer home at Narragansett Pier.

Ernest Sydney Lewis * New Orleans, University of Louisiana Medical Department, 1861, chairman of the Section on Obstetrics and Diseases of Women and Children of the American Medical Association, 1878-1880, professor of materia medica, therapeutics and clinical medicine 1873-1876, of materia medica and diseases of women, 1876-1911 and professor of obstetrics and clinical medicine 1873-1876, since 1911 professor of obstetrics and gynecology, emeritus, Tulane University of Louisiana School of Medicine, Civil War veteran, fellow of the American College of Surgeons, past president of the Southern Surgical Association in 1867 state

BARTON COOKE HIRST
1861-1935

health officer, for many years on the staff of the Charity Hospital and the Hotel Dieu Hospital, aged 94, died, August 12, in the Touro Infirmary, of bronchopneumonia.

Calvin C. Rush * Johnstown, Pa., University of Pennsylvania Department of Medicine, Philadelphia, 1907, member of the American Academy of Ophthalmology and Oto Laryngology and the American Ophthalmological Society, fellow of the American College of Surgeons, at one time assistant demonstrator of neuro-anatomy, Jefferson Medical College, Philadelphia, member of the school board and formerly health officer of Southmont, on the staffs of hospitals in Canton, China and Tokyo, Japan, 1918-1919, on the staff of the Conemaugh Valley Memorial Hospital, aged 59, died, July 19, of subacute bacterial endocarditis following sinus infection.

Gustav Ferdinand Ruediger * Pasadena, Calif., Rush Medical College, Chicago, 1903, member of the American Association of Pathologists and Bacteriologists, professor of bacteriology and pathology, and director of the state public health laboratories, University of North Dakota, Grand Forks, 1907-1914, director of the hygienic institute of La Salle, Peru and Oglesby, Ill., 1914-1917, director of the state hygienic laboratory of the University of Nevada, 1917-1921, director of the Pasadena Clinical Laboratory, aged 59, died, July 5, of heart disease.

Harry Belleville Eisberg * New York, University and Bellevue Hospital Medical College, New York, 1913, member of the Associated Anesthetists of the United States and Canada, fellow of the American College of Surgeons, instructor in surgery at his alma mater, aged 42, at various times on the staffs of the United States Marine Hospital, Staten Island, the Riverside Hospital, Harlem Hospital, Sydenham Hospital and the Manhattan General Hospital, where he died, August 10, of acute appendicitis and coronary heart disease.

Henry Lincoln Wolfner * St. Louis, Missouri Medical College, St. Louis, 1881, at one time professor of clinical ophthalmology, Washington University School of Medicine, for nine years a member, and at one time president, of the board of education, aged 74 on the staffs of the Bethesda Hospital and the Jewish Hospital, where he died, July 11, of chronic myocarditis.

James Ross Allen * Olean, N. Y., Queen's University Faculty of Medicine, Kingston, Ont., Canada 1894, fellow of the American College of Surgeons, past president of the Cataraugus County Medical Society, on the staff of the Olean General Hospital, aged 65, died, August 11, in the Buffalo General Hospital, of heart disease.

Justus Lee Cooke * Fredericksburg, Va., College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1893, past president of the Fredericksburg Medical Society, health officer of Fredericksburg, on the staff of the Mary Washington Hospital, aged 62 died suddenly, August 6, of cerebral hemorrhage.

Clarence Joseph D'Alton * New York, Medical College of Virginia, Richmond, 1910, member of the American Psychiatric Association and the Association for Research in Nervous and Mental Disease, on the staff of the Neurological Institute, aged 45, died, July 12, in the Hartford (Conn.) Retreat, of cerebral edema.

Chester Edson Gates, Anoka, Minn., University of Minnesota Medical School, Minneapolis, 1904, member of the Minnesota State Medical Association, president of the board of education, medical director and owner of a hospital bearing his name, aged 56, died June 24, in the Swedish Hospital, Minneapolis.

Jonas Edward Bacon, Brockton, Mass., Harvard University Medical School, Boston, 1878, member of the Massachusetts Medical Society, member of the exemption board during the World War, on the staff of the Brockton Hospital, aged 81, died, July 31, of chronic myocarditis and arteriosclerosis.

George A. Rohrer, Spokane, Wash., Julius-Maximilians Universität Medizinische Fakultät, Würzburg, Bavaria, Germany, 1902, member of the staff of the Sacred Heart Hospital, aged 60, on the staff of heart disease.

Joseph Jefferson Asch * New York, Columbia University College of Physicians and Surgeons, New York, 1902, member of the American Urological Association and the American Association of Surgeons, on the staff of the Lenox Hill Hospital, aged 55, died, August 15.

Caleb Noble Athey, Baltimore, University of Maryland School of Medicine, Baltimore, 1894, member of the Medical and Chirurgical Faculty of Maryland, at one time member of the city health department, and police surgeon, aged 66, died August 11, of paralysis agitans.

Kelley Charles Fitzgerald, New Harmony, Ind., Kentucky School of Medicine, Louisville, 1906, member of the Indiana State Medical Association, past president of the Posey County Medical Society, served during the World War, aged 51, died, July 31, of coronary occlusion

Harry Hartsock Thompson, Philipsburg, Pa., Jefferson Medical College of Philadelphia, 1889, member of the Medical Society of the State of Pennsylvania, served during the World War, on the staff of the Philipsburg State Hospital, aged 68, died, July 3, of nephritis

Arthur Preston Clark, New Hartford, N. Y., Albany (N. Y.) Medical College, 1905, for many years health officer of New Hartford, formerly county coroner and school physician on the staff of the Faxon Hospital, Utica, aged 54, died, June 22, of lymphosarcoma

James Armitage Emery, Chevy Chase, Md., George Washington University School of Medicine, Washington, D. C., 1907, acting chief of the biochemic division of the bureau of animal industry, U. S. Department of Agriculture, aged 68, died, July 28, of heart disease

Marion Dorset, Washington, D. C., Columbian University Medical Department, Washington, 1896, also a chemist, since 1904 chief of the biochemic division, bureau of animal industry, U. S. Department of Agriculture, aged 63, died, July 14, of coronary occlusion

Tuite Howe Hanson, Donaldsonville, La., Tulane University of Louisiana Medical Department, New Orleans, 1895, past president of the Ascension Parish Medical Society and the Lafourche Parish Medical Society, aged 66, died, August 11, of heart disease

Marie Eloise Perez, Brooklyn, University of Michigan Medical School, Ann Arbor 1934, aged 25, intern at the Norwegian Lutheran Deaconesses' Home and Hospital, where she died August 5, of rheumatic heart disease and bronchopneumonia

Loyal Dexter Rogers, Chicago, Hahnemann Medical College and Hospital, Chicago, 1884, Rush Medical College, Chicago, 1896, aged 78, died, July 25, in St. Luke's Hospital of prostatitis, pyelonephritis, chronic myocarditis and hypertension

Henry Thomson Cummings, Chicago, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1903, on the staff of the Jackson Park Hospital, aged 54, was found dead, July 30, of chronic myocarditis

Frederick Bryant, Worcester, Mass., Harvard University Medical School, Boston, 1900, member of the Massachusetts Medical Society, aged 63, died, July 29, at his summer home in Hull of cerebral hemorrhage and chronic myocarditis

John Joseph Dowling, Boston, Harvard University Medical School, Boston, 1894, served during the World War, medical director and superintendent of the Boston City Hospital, aged 65, died, July 10, of cerebral thrombosis

Marion Wollaston Ueberroth, Tiffin, Ohio, College of Physicians and Surgeons, Baltimore, 1893, past president of the Seneca County Medical Society, on the staff of the Mercy Hospital, aged 63, died, July 7, of heart disease

Francis Joseph Hanley, Whitman, Mass., Jefferson Medical College of Philadelphia, 1893, past president of the Plymouth District Medical Society, served during the World War, aged 66, died suddenly, August 2

Chester B. Nuckolls, Hillsville, Va., Baltimore Medical College, 1893, University College of Medicine, Richmond, 1894, member of the Medical Society of Virginia, aged 68, died, June 28, in the Lakeside Hospital, Cleveland

Clifford Leslie Kaucher, Reading, Pa., Medico Chirurgical College of Philadelphia, 1902, served during the World War, for many years on the staff of St. Joseph's Hospital, aged 54, died, July 2, of cirrhosis of the liver

William Thomas Clemes, Blissfield, Mich., Trinity Medical College, Toronto Ont., Canada, 1895, at one time member of the school board and village health officer, aged 67, died, July 30, of cerebral hemorrhage

Leon Irving Sass, Brooklyn, Columbia University College of Physicians and Surgeons, New York, 1935, aged 24, died, July 12, in the Mount Sinai Hospital, New York of a skull fracture received in a fall

Edgar C. Freas, Memphis, Tenn., Vanderbilt University School of Medicine, Nashville, 1883, aged 75, died, July 25, in the Baptist Hospital of pneumonia, following a fracture of the hip received in a fall

Calvin Graham Dold, Buena Vista, Va., University of Maryland School of Medicine, Baltimore, 1891, member of the Medical Society of Virginia, aged 65, died, June 22, of carbuncle of the neck

Gordon Berge McNicol, Dixon III, Northwestern University Medical School, Chicago, 1935, aged 26, died, June 26, in the Cleveland (Ohio) City Hospital, of subacute bacterial endocarditis

George Clinton Ballard, Little Rock, Ark., University of the South Medical Department, Sewanee, Tenn., 1898, served during the World War, aged 65, was found dead in bed July 29

Mary Thayer Ritter, Angola, Ind., Medical College of Indiana, Indianapolis, 1903, secretary of the Steuben County Medical Society, aged 65, died, July 19, of carcinoma of the cecum

David Mathew Butler, Boston, Tufts College Medical School, Boston, 1915, aged 45, died, August 1, in the Cambridge (Mass.) Hospital, of injuries received in an automobile accident

John A. Henry Helfrich, Allentown, Pa., Hahnemann Medical College of Philadelphia, 1875, aged 81, died, recently, in the Allentown Hospital of hypertrophy of the prostate

Walter James Donovan, Pacific Beach, Calif., Tufts College Medical School, Boston, 1910, served during the World War, aged 52, died, July 24, of uremia and nephritis

John Wesley Quinlan, Syracuse, N. Y., Albany (N. Y.) Medical College, 1888, aged 70, died, July 11, in the Onondaga General Hospital of hemorrhage due to gastric ulcer

Wallace Marcell Pierce, Burlington, Vt., University of Vermont College of Medicine, Burlington, 1898, aged 63, died suddenly, June 3, of coronary thrombosis

Emma Catherine Hackett, Dubuque, Iowa, Northwestern University Woman's Medical School, Chicago, 1900, aged 64, died, July 6, of cerebral hemorrhage

Edward McLoughlin, Chicago, Rush Medical College, Chicago, 1890, aged 83, died, July 1, in the Evangelical Hospital, of carcinoma of the intestine

John P. Eisenberger, Cherry Creek, N. Y., University of Buffalo School of Medicine, 1919, aged 45, died, July 5, of chronic encephalitis

Ward A. Johnson, Monroe, Ind., Toledo (Ohio) Medical College, 1889, aged 75, died recently of angina pectoris and chronic myocarditis

Prince Oliver Wailes, Mansfield, La., Meharry Medical College, Nashville, Tenn., 1909, aged 70, was found dead in his office recently

William James Derby, Westboro, Ont., Canada, McGill University Faculty of Medicine, Montreal, Que., 1882, aged 80, died recently

Henry E. Rakestraw, Chanute, Kan., Homeopathic Medical College of Missouri, St. Louis, 1874, aged 84, died, June 24, of senility

Guy Darwin Small, Palestine, Texas, Baltimore University School of Medicine, 1902, aged 61, died recently of brain tumor

Herbert H. Frazier, Hanover, Mich., Baltimore Medical College, 1893, aged 66, died, July 26, of pernicious anemia

Stella M. Clarke, Los Angeles, Homeopathic Hospital College, Cleveland 1888, aged 75, died, July 12

Bureau of Investigation

CURTIS HOWE SPRINGER

A Quack and His Nostrums

Curtis Howe Springer first came to the attention of the Bureau of Investigation through a display advertisement published in the Davenport (Iowa) *Times* Oct. 2, 1929. This carried a picture of Springer who was described as "Dean of Greer College." The advertisement read in part as follows:

Money For You Develop Your Powers Be Healthy, Happy, Successful A series of Free Lectures Is offered to the public under the auspices of the Extension Department of Greer College.

Thousands have paid to hear these lectures, but you can hear them free through the courtesy of the Davenport Psychology Class.

President Hoover said the complete abolition of poverty is now a possibility for us.

Analyze Yourself Know Your Hidden Powers

Greer College, according to the Chicago Better Business Bureau, was a concern teaching automobile mechanics and went into bankruptcy with an unfavorable record of students untrained and loss to creditors. Later, according to the Better Business Bureau, the concern was reorganized. In answer to a letter written to Greer College July 24, 1935, by the Bureau of Investigation Mr. E. Greer stated that Springer's connection with that institution was terminated 'about five years ago.'

In August 1930 the Scranton (Pa.) Better Business Bureau wrote that Springer had been giving a course of 'lectures' at the local Y M C A which he is said to have claimed were presented through the courtesy of the 'Extension Department of the National Academy.' What this Academy is or was if, which seems doubtful, it ever has been, we have been unable to learn. Neither have we been able to learn anything about the "Springer School of Humanism" that was also mentioned. The Better Business Bureau reported, further, that Springer's 'lectures' were entitled "How to Banish Disease and Know the Joy of Living." Springer was said not to have charged any admission, but to have taken up a collection and also to have sold so-called private courses in psychoanalysis at \$25 a course.

In connection with the latter, the Scranton Better Business Bureau stated further that a local woman who had contracted and paid for a "course" charged Springer with obtaining money under false pretenses. When the case came up for trial, the woman is said to have testified that for the money paid, Springer had agreed to give her twelve "readings" or "sittings," two a week for six weeks, but that at the end of two weeks Springer left the city and she received no further notice from him. The Scranton Better Business Bureau reported that prosecution was dropped when Springer refunded the woman's money.

In December 1930 Springer put out what purported to be the first issue of a magazine entitled "Symposium Creative Psychologic," a name that is as meaningless as some of the titles that Springer has annexed. This sheet was devoted mainly to advertising Springer and his activities, especially his "Doc Springer Temple of Health." In it Springer published an "explanation" of why he had had to cease broadcasting over WBRE.

At this point it may be interpolated that investigation seems to show that Springer came originally from Birmingham, Ala., where his record, not being of a medical or quasi-medical character, need not be gone into at this time, he left there to come to Chicago, he organized the "Temple of Health" in Wilkes-Barre, Pa., he sold "Springer's Health Bread" at Johnstown, Pa., he exploited a similar scheme in Cumberland, Md., he made payments on some land at Mount Davis, near Salisbury, Pa., with the idea of starting a "health resort", he incorporated Basic Foods, Inc., with an authorized capital of fifty shares, of which Springer and another man were said to hold one share each and Springer's wife to hold the other forty-eight shares, he published in not-too-particular papers alleged health columns with his picture accompanying the reading matter.

During the past few years Curtis Howe Springer, in advertising himself, has placed after his name the letters 'M.D., N.D., D.O., Ph.D.,' sometimes with the statement beneath the

"degrees" that they were "Honorarily conferred." A most thorough search fails to show that Springer was ever graduated by any reputable college or university, medical or otherwise.

In May 1933 a physician in Cumberland, Md., wrote to the Bureau of Investigation, stating that when Springer had appeared in his locality the local state's attorney demanded that Springer produce a certificate showing that he had the right to use the title M.D. This, of course, Springer was unable to do. Then, according to our correspondent, Springer was charged with practicing medicine without a license, but, being at liberty without bail, he left Cumberland and could not be apprehended for trial. Later it was reported that he was broadcasting at Philadelphia and still later at Pittsburgh.

SPRINGER COMES TO CHICAGO

In the latter part of December 1933 the broadcasting station WGN, operated by the Chicago *Tribune*, called up the Bureau of Investigation of the American Medical Association and asked for, and received, such information as was then available on

Photographic reproduction (greatly reduced) of the cover of an alleged magazine put out by Springer as an advertising asset. At that time Springer affected long hair, since then he has had it cut. In this "magazine" Springer had an explanation of why he had to cease broadcasting over WBRE.

Curtis Howe Springer. It appeared that Springer wanted to buy time on the air over WGN, but the contract he offered was rejected. A few days later (Jan. 4, 1934) Springer himself, with the effrontery of his kind, came to the headquarters of the American Medical Association and asked to see the Director of the Bureau of Investigation. He told the Director that he had called to correct what he described as certain misconceptions that the Bureau of Investigation was said to have regarding him.

Springer was asked where he had obtained and by what right he used the degree M.D. He stated that the degree had been bestowed by one Frederick W. Collins, a chiropractor of New Jersey, who runs the egregious "First National University of Naturopathy" and apparently several other high-sounding institutions of dubious educational character. Needless to say, the Collins outfit is not a recognized medical college. It has no scientific standing and of course, has no legal authority.

whatever to grant the degree of Doctor of Medicine Springer further admitted during the interview that his alleged degrees were granted without attendance and upon the payment of either \$200 or \$300 (he said he could not remember which) and the answering of certain questions!

Springer was told that interviews were unsatisfactory, as they left the problems discussed a matter of recollection on the part of two individuals. For that reason he was requested to send the Bureau of Investigation a letter setting forth the various facts regarding himself and correcting any alleged inaccuracies of which the Bureau of Investigation had been accused. At the time, Springer stated that he would go right back to his hotel (one of the most expensive in Chicago) and write such a letter.

Within five minutes of the termination of the interview the Director of the Bureau of Investigation wrote a letter to Springer at his address in the hotel in Chicago, setting forth exactly the claims that he had just made. He was asked to confirm by letter his verbal claim that he had paid \$200 or \$300 for his M D "degree" granted by chiropractor Collins who had no right to grant such a degree, he was asked from what institutions and on what dates he had received his "degrees" of N D, D O and Ph D, he was asked whether the Greer College, of which he had been advertised as Dean, was the same concern that had been the subject of a cease and desist order from the Federal Trade Commission, he was asked, also to furnish, as he had promised verbally, written evidence to indicate that he had some knowledge of nutrition and dietetics and he was also asked to send any information he cared to regarding 'Doc. Springer's Temple of Health' at Wilkes-Barre, Pa. Needless to say, Springer was much too shrewd to fulfil his verbal promise to write a letter or to put in black and white answers to any of the questions that were put to him.

Although unsuccessful in buying time on the air over WGN it was not long before Springer was broadcasting twice daily over WCFL, another radio station operating in the Chicago area. In this connection, we cannot do better than quote from the Chicago Better Business Bureau's report on Springer's Chicago radio activities:

"These talks were along sensational lines tending to vilify those who disagreed with the New Deal and President Roosevelt's program. Appeals for money for his activities were made and, according to information received, many sent him funds. In the early summer of 1934 Springer brought out a newspaper called the *New Deal* which was labeled 'Official Organ of Legion of Honor'. The style 'Legion of Honor' was another creation of Springer's, the stated purpose of which was to federate honest, patriotic and loyal merchants into an organization known as 'Federation of New Dealers' that will afford the opportunity to enlighten the working man, the forgotten man and others seeking truth. Springer likewise carried on attacks against business establishments in Chicago, charging them with exploiting the public. Soon complaints started to come to the Better Business Bureau and a number of warrants were taken out for Springer in Chicago, charging him with slander, etc."

About the middle of July 1934 Springer is said to have come to the office of the Chicago Better Business Bureau for the purpose of giving information regarding certain complaints which existed against him. While he was there, he was asked some questions by the officials of the Better Business Bureau. Quoting again from that Bureau's report:

"When asked about his qualifications as a medical doctor Springer said that he took his degree of M D from the American College of Doctors and Surgeons in Washington, D. C. [There is no such institution.—Ed.] He took his degree of osteopathy at Meyersdale, Pa., where he maintained a residence. [There never has been an osteopathic college there.—Ed.] He states that he attended the Westlake West Virginia College for one year. [There is no such college and never has been.—Ed.] and further, that he took his degree of Ph D from a New Jersey school of osteopathy. When it was called to his attention that a school of osteopathy did not confer such a degree as Ph D., Springer did not answer the question.

'He advised that he had made \$76,000 in 1933 in the sale of his food products including Antediluvian Tea,

INTERVIEW DIVISION

Re-Hib, an anti-acid product, and the so-called Basic Food. Springer met the various complaints against him with counter-charges designed to discredit the complaints. About the middle of July he ceased broadcasting on radio station WCFL, following which complaints were received from business establishments alleging unsatisfied obligations left by Springer."

One incidental point, as showing Springer's character, is worth bringing out. While Springer was broadcasting in Chicago over radio station WCFL, he was defaming certain Chicago stores which were picketed because of strikes. At the same time Springer was staying at one of the most expensive hotels in Chicago which was also, both at that time and later, the subject of picketing!

Springer's statement to the Chicago Better Business Bureau that he had made \$76,000 in 1933 in the sale of his "patent

Photographic reproduction of the title page of a Springer booklet advertising his patent medicine Antediluvian Tea a mixture of chopped up herbs

medicines" Re-Hib, Antediluvian Tea etc., might be of interest to that portion of the Treasury Department that looks into income tax returns.

Since Springer wore out his welcome in Chicago, he has apparently been lying comparatively low—at least, the number of inquiries that have come in regarding him has been few. One did come in in April 1935 from the Philadelphia County Medical Society, which telegraphed the Bureau of Investigation of the American Medical Association, stating that a Philadelphia radio station was requesting advice on Springer's Re-Hib and Antediluvian Tea. The Philadelphia County Medical Society was told that Springer was not a physician and that the Bureau of Investigation considered him a blatant faker, that his Re-Hib was apparently mainly baking soda, while the Antediluvian Tea was evidently nothing more than a crude mixture of laxative herbs. The Bureau was later advised by the Philadelphia County Medical Society that the radio station had refused Springer's contract for broadcasting.

Because of the number of inquiries regarding Springer's "patent medicine" Re-Hib, the Bureau of Investigation asked the A M A Chemical Laboratory to make an analysis of the nostrum. The Laboratory report follows:

LABORATORY REPORT

"An original specimen of 'Dr' Springer's Re-Hib (Haven of Rest, Somerset County, Pa.), price 75 cents, was submitted to the A. M. A. Chemical Laboratory for examination. The only statement on the trade package that gave any information regarding composition read as follows: 'Re Hib is a blending of Magnesium Carbonate—Sodium Carbonate—Bismuth Subcarbonate—Milk Sugar—Papain—Malt Diastase and Oil of Peppermint. Sodium Bicarbonate Added'.

"The jar contained 137.8 Gm (4.4 oz approximately) of a white powder possessing an odor of oil of peppermint. Qualitative tests indicated the presence of bismuth, calcium, magnesium, sodium, bicarbonate, carbonate, lactose, and traces of chlorides, sulphates and oil of peppermint. Phosphates, nitrates, boric acid and borates were not found. Pharmacognostic examination indicated the absence of starch and cellular animal or vegetable tissue. Under a rotatory microscope the following substances appeared to be present: Sodium bicarbonate, sodium carbonate, lactose, bismuth subcarbonate and magnesium carbonate. Quantitative determinations yielded the following:

	per cent
Loss on drying (100 C)	26.9
Loss in weight in vacuum over sulphuric acid	0.06
Ash	57.0
Bismuth (Bi+++)	2.05
Calcium (Ca++)	2.2
Magnesium (Mg++)	2.65
Sodium (Na+)	20.85
Carbon dioxide (CO ₂)	45.30
Lactose	5.2

"Based on the foregoing, it may be calculated that Springer's Re-Hib contains essentially the following:

	per cent
Sodium bicarbonate (baking soda)	72.3
Magnesium carbonate (magnesia)	10.9
Calcium carbonate (chalk)	5.6
Lactose (milk sugar)	5.2
Sodium carbonate (washing soda)	2.8
Bismuth subcarbonate	2.5
Difference (moisture, oil of peppermint, etc.)	0.7

"The product appears, therefore, to be approximately three-fourths baking soda, to which has been added some magnesium carbonate (magnesia), bismuth subcarbonate, and calcium carbonate (chalk).

From the label, which states, after naming the alleged ingredients, that sodium bicarbonate (baking soda) has been "added" to Re-Hib, one would naturally assume that this substance was but a minor ingredient or an afterthought. Yet from the chemists' report, it is obvious that baking soda comprises nearly three-fourths of Springer's "patent medicine."

Summed up, it may be said that Springer is but one more example of what to the thoughtful citizen must appear as one of the most dangerous social phenomena of American city life. The person with an ignorance of the human body and its processes that is wide and deep, who by virtue of an unblushing effrontery combined with a flair for garrulity dupes an ignorant public. Loquacious fakers, faddists and quacks have for some years past made an easy living by their wits through the facility with which they could hire halls and announce so-called free lectures on subjects on which the ignorance of the audience was only exceeded by that of the speaker. The advent of the radio has multiplied the opportunities for dispensing misinformation at the public's expense.

The Caliber of the Fallopian Tube—The caliber of the tube is very small, especially at its inner end, where the canal is only large enough to admit a very fine bristle. It can thus be seen that the slightest obstruction, as by even a mild degree of the inflammations which are so common in women, may block the channel so that eggs cannot reach the womb. This is one of the most common causes of childlessness in women, and it is this point which the gynecologist tries to clear up by means of blowing carbon dioxide gas through the tube in the now well known Rubin test.—Novak, Emil. *The Woman Asks the Doctor*, Baltimore, Williams and Wilkins Company, 1935.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

COPPER IN COOKING UTENSILS AND IN FOOD

To the Editor—I have a refrigerating basket that I use when I go fishing. A tinner told me that it would not be advisable to replace the tin lining with copper, as it would poison the fish. A candy manufacturer advises that he does all his cooking in copper utensils but that he never allows any of the products to cool in such containers. Please advise whether copper is harmful as a lining for such a basket and if so just what the cause is.

M D Mississippi

ANSWER—The flesh of some fish in many waters, and particularly some shellfish, regularly contains more copper than would arise from contact with a copper fish basket. Water has a slight capacity for dissolving copper, one gallon dissolving approximately one-fifth grain. If all this should be taken up by fish, subsequent consumption of the fish probably would not lead to disaster. A great deal of food is prepared in copper vessels. It is a common experience of many housewives to cook up fruit in copper utensils. Much home made molasses is prepared in copper pans. In many industries presumably using tin-lined copper vessels, the tinning becomes worn off so that cooking actually takes place in copper vessels. In some countries, copper vessels are regularly used. None of these uses lead to copper poisoning of any severity. The housewife knows that such foods as preserves prepared in copper vessels must not be permitted to stand indefinitely. Long standing leads to marked green discoloration of the syrup around the edges. Such a quantity of copper would either prove to be unnoticed at the time of consumption or at most would cause a gastro enteritis. None of these statements imply that the copper ion is not toxic. Preferably copper utensils used in connection with food should be tinned, the tin being even less toxic than the copper. Copper compounds have led to a number of deaths both accidentally and as a result of use for suicide. The quantity necessary to produce death or other serious consequences is quite high. As much as one half ounce of copper sulphate has been ingested by a young child without fatal results. Long continued exposure to traces of copper is not proved to lead to any chronic copper poisoning. Industrial workers exposed to copper in various forms ordinarily suffer no severe consequences. The use of copper for coloring foods has been the subject of much contention and controversy. Different conclusions have been reached by various nations. At one time in this country it was concluded that from 10 to 12 mg of copper (representing the upper limit of the small quantity that might be utilized in the artificial "greening" of a day's ration of vegetables and continuously taken into the body) might bring about a prejudicial effect on health. When acute poisoning does follow the ingestion of copper compounds, chief manifestations are nausea, vomiting accompanied by thirst, abdominal pain, marked diarrhea and acute nephritis, followed in profound cases by convulsions, delirium and collapse. However, it is the intent of this discussion to deny the likelihood of harm from the use of copper as a material for making refrigerated fish baskets.

SCHILLER'S TEST—DARANYI REACTION—HIRSCHFELD'S CANCER REACTION

To the Editor—Please describe for me the technique of (1) Schiller's test (2) the Daranyi reaction and (3) Hirschfeld's cancer reaction.

MARIO D BEJASA M D Philippine Islands.

ANSWER—1 Schiller's test for the detection of early carcinoma of the cervix is based on a discovery by Lahm that the upper layers of the normal epithelium of the portio and the vagina contain rich masses of glycogen, which disappear when the epithelium becomes cornified or changed by cancer. In the normal living tissue the glycogen of the upper layers of cells is stained in a few seconds a deep mahogany brown by compound solution of iodine. A superficial area of early cancer, being devoid of glycogen, does not receive the stain and stands out startlingly white or pink against the deeply colored almost black background of the normal tissue. Schiller (*Am J Surg* 26:269 [Nov] 1934) said that he used preferably Gram's solution, consisting of one part of iodine to two parts of potassium iodide and 300 parts of water, as it gives sharper differentiations than the more rapidly acting but much more diffusely staining compound solution of iodine of high concentration. The portio should first be cleansed of mucus

or discharges with the aid of cotton. Then from 20 to 30 cc. of Gram's solution is poured on the portio from a glass vessel having a sharply pointed lip and is carefully distributed with a cotton pledget, so that no part shall remain unmoistened. After thirty or forty seconds the Gram's solution is absorbed with a pledget of dry cotton, the portio is wiped off superficially and is then carefully examined for staining.

2. The Daranyi test is said to be an aid in the diagnosis of tuberculosis when some other tests give doubtful results. According to Montank (*Journal-Lancet* 45 62 [Feb 1] 1925) the test is made with 0.2 cc. of the serum added to 1.1 cc. of 96 per cent alcohol diluted with 2 per cent sodium chloride solution (4.1 cc. of the saline solution to each cubic centimeter of the alcohol). The mixture is well shaken and heated in the water bath at 60 C. for twenty minutes. The tubes are then kept slanted at room temperature against a dark background and are inspected without disturbing. When flocculation occurs at the half or first hour, this is a four plus reaction. The negative reaction is recorded at the end of twenty-four hours if no flocculation has occurred. It is important to titrate the alcohol dilution each time with control serums.

3. Hirschfeld's cancer reaction, according to A. I. Lipkin (*Giornale di batteriologia e immunologia* 9 605 [Oct] 1932) is carried out as follows. The carcinomatous tissue is cut into small pieces and is placed in a 96 per cent alcoholic solution in a ratio of 1 to 10 and kept for nine days in a thermostat the mixture being shaken vigorously from time to time and then filtered through paper. The filtrate represents the extract. For the preparation of antigen 1, 0.35 cc. of this alcoholic extract is added to 0.15 cc. of a 1 per cent alcoholic solution of cholesterol, for the preparation of antigens 2 and 3, 0.3 cc. and 0.2 cc. are added, respectively. To each 0.5 cc. of the mixture, 3 cc. of physiologic solution of sodium chloride is added. The antigens give a positive reaction with the serum of healthy persons in amounts of 0.3 cc. of antigen 1, in amounts of 0.4 cc. of antigen 2 and in amounts of 0.5 cc. of antigen 3. For the titer, 0.25 cc. is used for antigen 1, 0.35 cc. for antigen 2 and 0.45 cc. for antigen 3. To perform the test, the required amount of the antigen is poured into each test tube (depending on the titer) and the volume is brought up to 0.5 cc. with physiologic solution of sodium chloride, then 0.5 cc. of the serum to be examined is inactivated and diluted five times with physiologic solution of sodium chloride and 0.5 cc. of complement (fresh blood serum of guinea-pigs diluted to the right titer with physiologic solution of sodium chloride) is added. The test tubes are placed in a thermostat for an hour and then 1 cc. of the hemolytic system is added. The tubes are again placed in a thermostat for an hour, and then the results of the test are read. Hirschfeld and his associates consider that with especially selected and sensitive antigens it is possible with the complement fixation reaction to detect in cancer patients antibodies for cancer lipids.

POISONING WITH CYANOGAS

To the Editor.—A patient came to me recently who had been rendered dizzy and sick from the inhalation of cyanogas. He states that to clear the mouth of the can he put it to his lips and blew through it. Now from two to three weeks later he has still considerable fullness in both ears the mucous membranes of the nose and throat are swollen and there are pains along the jaws in front of the ear. Could you tell me how this gas would cause trouble in tissues of the head and the respiratory tract? Would there be any late effects on the blood or kidneys or lungs?

M.D. Rhode Island

ANSWER.—In defense of the manufacturer of this product it is pointed out that the printed descriptive literature carries many warning statements such as "Do not inhale with mouth or nose close to open container." One of the paradoxes of the industrial use of cyanides is the almost entire absence of clinical cases even when cyanides are manipulated in large quantities occasioning visible clouds of cyanide dust. Possibly this apparent lack of toxicity is due to some form of tolerance built up by long exposed industrial workers. In the case described Cyanogas is stated by its manufacturers to be calcium cyanide $\text{Ca}(\text{CN})_2$, but the marked local manifestations mentioned in the query suggest the action of calcium cyanamide, CaCN_2 . These two substances are chemically closely related although by no means identical. The cyanamide produces intense inflammation of the mucous membranes with conjunctivitis, rhinitis, gingivitis and in fact, inflammation along the entire respiratory tract. Further, the cyanamide may lead to typical skin lesions, which are deep red or bluish and in some instances similar to the scarlatiniform rash of scarlet fever. Although systemic disease may arise from the cyanamide, it is less characteristic than from the cyanide. In subacute poisoning by the latter the following symptoms may arise: dyspnea, profound weakness, pains in the

head and in the region of the kidneys, redness of the skin, accelerated pulse, which is usually feeble, difficult and irregular breathing, marked vomiting, and spasm of the diaphragm and of the abdominal muscles. This type of manifestation may continue with some severity for two or three weeks. However, for six or eight months the patient suffering from cyanide poisoning may exhibit a distinct anemia, marked fatigability, abnormal gait and posture, involvement of the small muscles about the face, and difficulty in moving the jaw. In answer to the specific question as to late effects, it may be stated with certainty that long after the period of exposure to cyanides the victim of cyanide poisoning may suffer from damage to the blood and kidneys' action on the lungs and respiratory tract is not well established for cyanides but is associated with cyanamide poisoning.

RHEUMATIC FEVER

To the Editor.—I should like your advice regarding a girl who is now 13 years of age and who had severe rheumatic fever at the age of 10. In December 1931 she had joint pains and high fever. Previous to this her history had been negative for rheumatic fever, colds or tonsillitis, although a soft systolic blow on exercise had been noticed on examination two months previously. From December until the end of February the girl exhibited practically all the textbook signs of rheumatic fever, namely nosebleeds, nodules pain in the breasts, petechiae and purpuric spots as well as various signs of carditis, joint pains and fever. Feb. 27, 1932, she was taken to Bermuda by stretcher to the boat having been kept flat on her back at all times during her illness. In Bermuda she did not pick up rapidly until July when the physician there felt that she was well enough for tonsillectomy. This he did and it seemed as though from this moment her recovery set in. She returned to this country in August 1933. Her heart at this time appeared to be normal in size. The sounds were of fair quality with extrasystoles every five to fifteen beats unaffected by exercise; no murmur was heard at this time. She was allowed to lead a normal life with the exclusion of strenuous games. March 12, 1934, an electrocardiogram showed no definite evidence of active myocardial involvement. In lead 4 the P wave was inverted, T inverted and QRS diphasic. White blood cells numbered 9,100; there was a normal sedimentation rate. She has continued in excellent health since her return from Bermuda and apparently has had no recurrence of rheumatic activity. At present she has no cardiac symptoms, does not get out of breath more easily than other girls, plays baseball and takes walks but does not play basketball, she would like to play tennis. She is a fine strong looking girl, weighs 108 pounds (49 Kg.) and is 63 inches (160 cm.) in height. The hemoglobin is 97 per cent. The heart is normal in size on palpation and to percussion. The rate is about 84 and very irregular there being very frequent extrasystoles coming mostly in pairs. On exercise running downstairs around a room and up again the pulse goes to 135 and is perfectly regular. In one minute it is still regular and down to 100. In two minutes it is back to 80 with extrasystoles recurring. No murmurs are heard. The problems in which I should like help are these: What is the significance of the extrasystoles? I have talked to many doctors about this and there seems to be no definite knowledge about them. The general feeling is that in youth anyway they are not of grave import. How much can the girl be permitted to do? Should she be allowed to play any game that she wants to?

G. L. Johnson M.D. Englewood N. J.

ANSWER.—Extrasystoles of ventricular origin are not of any definite significance. In this case they may mean nothing at all or only that the previous infection has left some place in the ventricular muscle that is more irritable than normal. That also is of no consequence. If the extrasystoles are of auricular origin, they are of some significance and should be watched.

The only real danger is that of a recurrence of the rheumatic fever or that it is not entirely quiescent. This should be checked by careful reexamination at frequent intervals, the temperature being watched and repeated sedimentation tests being made.

SUBARACHNOID BLOCK

To the Editor.—Would it be safe to repeat a subarachnoid block with an anesthetic within ten days? If not, how much time should lapse before it would? Please omit name.

M.D. South Carolina

ANSWER.—It is considered safe to repeat subarachnoid block with a spinal anesthetic within ten days (Sullivan, W. M., Jr. Observations on a Patient to Whom Spinal Anesthesia was Administered Five Times Within Thirty-Eight Hours, *THE JOURNAL*, Sept. 17, 1932, p. 993) provided lumbar puncture headache has not developed from the first block, provided other untoward symptoms that might be referable to the first injection have not appeared or provided the patient tolerated the first block well at the time of operation. It would not be considered safe to repeat the block in the interval named if the patient became markedly debilitated in the period following the first operation and anesthesia. It is commonly understood that general debility is usually the principal contraindication to the use of spinal anesthesia.

For the uncomplicated case, such as one in which colostomy is to be followed later by partial resection of the bowel, a second and even a third spinal anesthetic for, say, closure of the colonic stoma, is commonly administered without special regard to the length of time between operations

PLASTIC INDURATION OF PENIS

To the Editor—I have a patient aged 48 years who is a strong robust farmer. About ten years ago the man was herding cattle and was thrown from his horse into a patch of poison ivy. This affected the penis and scrotum the perineal region and both thighs and in spite of the medical care which he received this condition persisted for over nine months when he changed physicians and was cured. Ever since this time he has had some pruritus of the penis. About five years later while breaking a bronco he was thrown rather hard against the saddlehorn with considerable hematoma resulting in the penis but which seemingly cleared up without any consequences. About two years after this injury he noticed that the urethra was becoming a hard pipelike affair at about the middle of the penis. Last winter while performing nature's duties outside in the cold he allowed the penis and testicles to become well frost bitten and ever since that time he has noticed that this hardened area in the penis has been increasing both in circumference and in length. Physical examination reveals that it is really two separate places. They feel like calcification around the urethra. The Wassermann reaction is negative. Examination of the urine is negative. Blood counts are normal and there is nothing in the general physical condition of the patient that deviates from the normal. As he is still active sexually this condition is a distinct aggravation and is a source of much pain while he has an erection. Urethroscopic examination is negative except for a slight constriction in the lumen of the urethra at the aforementioned places. Suggestions as to diagnosis and possibilities in treatment would be appreciated.

M D South Dakota

ANSWER.—From the description of this case it would appear that one is justified in making a diagnosis of so-called Peyronie's disease, sometimes called plastic induration of the penis, chronic cavernositis, circumscribed fibrosis, or primary indurative cavernositis, the etiology of which is unknown. (Of course there is a possibility that the patient may have a traumatic stricture.)

Various forms of treatment are recommended for this condition, hence it is evident at once that there is no specific form of treatment. Most urologists, however, agree on the following: 1. The patient should soak the penis in a pitcher of hot water morning and evening. 2. After the evening soaking the patient should massage with a 2 per cent iodine ointment made with vanishing cream as a base. 3. Internally, 1 Gm (15 grains) of potassium iodide should be administered three times a day.

If the patient has foci of infection elsewhere in the body that might play a part in this condition, they should be cleared up. The use of radium has not accomplished much. Diathermy occasionally helps. In a few instances, deep intramuscular injections of 1 cc. of thiosinamine in a 1 per cent solution every five days has proved helpful.

Surgical excision of these plaques has been recommended, but in a great many instances the condition has been aggravated by surgical operation; hence surgery is rarely, if ever employed. In a few instances the response to treatment is good—that is, the condition shows improvement, and in rare instances it clears up to a marked degree, but this favorable outcome is the exception rather than the rule. In the majority of cases the condition is resistant to treatment and shows but little improvement.

SENSITIVITY TO PITUITARY EXTRACT

To the Editor—I am expecting to attend a maternity case a duo decimpara aged 41 who after an injection of 0.5 cc of solution of pituitary in her last two labors developed allergic phenomena such as dyspnea and urticaria which slowly yielded to 0.5 mg of epinephrine and lasted twenty-four hours. Her mother had inveterate asthma and died of nephritis at 65. Will desensitization by injecting 0.05 cc of solution of pituitary with 0.5 cc of solution of pituitary with 0.5 Gm of epinephrine some fifteen minutes before injecting 0.5 cc. of solution of pituitary not nullify the oxytocic action of the solution of pituitary? Kindly suggest a procedure to avoid allergy for in this particular case solution of pituitary proved helpful. Please omit name.

M D San Pablo Philippines

ANSWER.—The query does not indicate that there has been a determination made as to the particular specific factor in the solution of pituitary that was responsible for the allergic reaction. The patient may be sensitive to the protein of the animal species from which the extract was derived. Thus she may react to the pituitary extract from the hog and not to that derived from the cow. This would indicate a species specificity, and allergic tests might indicate that a particular brand could be used safely. It is also possible that the patient may be sensitive to some fractions of the extract and not to others. Thus F. A. Simon (THE JOURNAL, March 23, p. 996) report-

ing an instance of hypersensitiveness to posterior pituitary extract, demonstrated on his patient a positive skin test with pituitary extract (obstetrical) and pitressin (vasoconstrictor principle) but a negative reaction to pitocin (oxytocic principle). If this could also be found in the inquirer's patient, the remedy would be evident.

Except from a scientific standpoint to determine what could be done in such an instance, it is doubtful whether the object to be gained would justify efforts at desensitization procedures, premature labor might well be induced in the process. Normal labor can, of course, be carried to termination without the aid of solution of pituitary.

ULCERATIONS IN MOUTH DURING MENSTRUATION

To the Editor—A white woman aged 35 unmarried 5 feet 7 inches (170 cm) high a brunette weighing 121 pounds (55 Kg) had the usual childhood diseases except measles which she had when 17 away at school. Several months later she had trouble with her eyes diplopia finally developed which was corrected by glasses. She began to menstruate at 11 years (twenty-eight day cycle from four to six days duration, with some slight dysmenorrhea). For the past three to five years she has menstruated irregularly from twenty-one to twenty-three days, with a duration of two or three days and very scant flow with no pain. As far back as she can remember she has suffered constantly with ulcers on the tongue and buccal surfaces. This condition is aggravated just before menstruation as a rule. They are from 2 to 5 mm in diameter round and somewhat depressed and covered with a grayish membrane which somewhat resembles thrush or a stomatitis. Removal of the membrane leaves a bleeding surface. Smears show pus cells but no definite organisms. There is a questionable enlargement of the thyroid. The basal metabolism has not been determined and a gastric analysis has not been made. She is not nervous and has no fever. The pulse at rest is 70 a minute after exercise 92 and after two minutes rest 80. On moderate exertion there is some shortness of breath and palpitation of the heart. There is no evidence of any pathologic condition of the heart or lungs. She has gained 20 pounds (9 Kg) in the last year. Her mother suffered with the same complaint until she was about 40 years old. The patient's sister has had no trouble like this nor has any of her four brothers. She catches cold easily and has catarrh and indigestion. Urinalysis is negative. Blood examination reveals 4,000,000 red cells and 80 per cent hemoglobin (Dare). She suffers with constipation as does most of the family. She lives in a malarial district. The family explains that the malaria is caused by a sluggish river. The patient has had fever and chills though not recently. In the last seven years she has been to as many doctors. None have given her any permanent relief. Many diagnoses have been made such as hyperacidity (increased pH of the blood), intestinal intoxication, nervousness and endocrine dysfunction. Each doctor has specified different diets all to no avail. Please outline treatment and medication. Would either emetine hydrochloride or small doses of neosarsphenamine help the local condition? Would solution of anterior pituitary and ovarian extract plus thyroid help her general condition? Please omit name.

M D South Carolina.

ANSWER.—The most distinctive symptom presented by this patient, and apparently the one concerning which advice is sought, is the appearance of small ulcerations on the mouth surfaces, especially at or near the time of menstruation. This should at once suggest the possibility of a chronic relapsing form of agranulocytic angina, in which just such ulcerations are associated with a periodic sharp drop in the polymorphonuclears. The correspondent reports the erythrocyte count but not that of the white cells. If not already done, this point should be cleared up by frequent white cell counts. For a discussion of this subject the correspondent is referred to

Jackson Henry Jr and Merrill Dudley. Agranulocytic Angina Associated with the Menstrual Cycle. New England J. Med. 210:175 (Jan.) 1934.

Thompson W. P. Observations on the Possible Relation Between Agranulocytosis and Menstruation with Further Studies on a Case of Cyclic Neutropenia. New England J. Med. 210:176 (Jan.) 1934.

Studies of the hormone output, according to the method followed by Thompson in his case, would be of interest if practicable. In the event of a periodic leukopenia being demonstrated, the employment of pentnucleotide, in daily intramuscular doses of 10 cc. for a week or ten days before menstruation and of gonadotropic factor of pregnancy urine (antuitrin S or follutin) in daily intramuscular doses of 2 cc. at the same time in relation to the periods, may prove beneficial (Jackson and Merrill).

Other than this suggestion as to specific possibilities, it would seem advisable to have a basal metabolism determination. If the rate is low or even if it is normal, desiccated thyroid in a daily dose of perhaps 0.065 or 0.01 Gm (1 or 1½ grains) may prove of benefit.

ICTERUS IN SYPHILIS

To the Editor—A man aged 25 has syphilis. The initial lesion occurred Dec 2 1934. Dark field examination was positive. December 4 Treatment was started the same day, iodobismutol being injected intramuscularly every fifth day. Neosarsphenamine was begun with an initial dose of 0.4 Gm the dose being increased to 0.6 Gm weekly intravenously. Four days after the seventh dose of neosarsphenamine an icterus developed. The patient was very ill for about two weeks. He received the usual treatment and was in a hospital. At the end of the third week the skin was fairly clear. He was put on mercury rubs for six weeks. Iodobismutol was resumed. The patient has gained weight rapidly during the past month. He has been serum negative from the start. Would you advise me to resume neosarsphenamine or to keep him on iodobismutol and mercury? I am positive that this was a case of arsenical hepatitis. What is the status of Parke Davis's mapharsen regarding its toxicity and would it be safe to use in a case of this kind? By the usual treatment I mean the usual one for arsenical poisoning. For three weeks he received no syphilitic treatment at all. Please omit name.

M D Illinois

ANSWER.—Icterus occurring in the early stages of syphilis during treatment with arsphenamine has been variously interpreted. A small percentage of these cases have been considered to be instances of early hepatic syphilis with jaundice. Another explanation is that it is a catarrhal jaundice of an infectious type.

French writers, particularly Milian, look on these cases as instances of a hepatorecurrence due to incomplete destruction of spirochetes stored in the liver. The majority of clinicians believe that the icterus is directly due to the toxic effect of the arsphenamine on the liver. The early resumption of neosarsphenamine treatment in this case is not advisable. The possibility of the development of an acute yellow atrophy of the liver should be borne in mind. The van den Bergh reaction is a useful guide to the resumption of treatment in patients who have been jaundiced. Mapharsen is a recently introduced arsenical that is still under clinical trial, it does not yet stand accepted by the Council on Pharmacy and Chemistry.

IRRITATION OF THIGHS IN RIDER

To the Editor—A man has been getting a papular eruption on the posterior and inner surfaces of both thighs. A few lesions are present on the flexor surfaces of both forearms. The papules are about 10 mm in diameter slightly infiltrated and not itchy. A few are raised at the margins and have centers slightly wrinkled. Roentgen treatment appears to flatten the lesions but others continue to appear. Whitfield's ointment and permanganate soaks have no effect. The patient goes horseback riding every morning. The lesions on the thigh are where the saddle comes in close contact. The lesions on the forearms are where the reins touch occasionally. I believe that the condition is dermatitis from leather. A patch test with leather is negative. Please let me know whether any similar cases have been reported and whether there is any way to protect this man from the leather if that is the cause as he does not want to give up riding.

M D Ohio

ANSWER.—From the meager description of the essential lesion it is difficult to draw any definite diagnostic conclusions concerning the eruption in question. The presence of papules on the flexor surfaces of both forearms with raised margins and slightly wrinkled centers (Wickham's striae?) suggest the possibility of the eruption being lichen planus. In this condition however, one would expect itching to be present.

The possibility of the eruption being a part of a lichen simplex chronicus has to be borne in mind also, and the contributory role of friction taking place in the course of horseback riding must be considered. The possibility of a fixed drug eruption must also be ruled out, and any history of the ingestion of drugs taken as cathartics or for analgesic purposes must be gone into.

In the case of "dermatitis from leather," in this instance there is probably no direct leather contact to the thighs but there is such contact to the forearms. In the case of the forearms, the wearing of long sleeves would protect these areas from the friction of the reins.

ORTHODONTIA

To the Editor—In the case of a boy aged 16 years with a receding lower jaw and malocclusion and some teeth with bad alignment, is he still young enough to expect any help from orthodontic treatments? Will braces be likely to cause a loosening of the teeth and eventually necessitate extraction?

EUGENE C LOWE, M D Miami Fla

ANSWER.—The condition described can be treated, and normal relation of the teeth established at 16 or even later, although the correction can be made more easily before the eruption of the second permanent molars, the so-called twelve-year molars. The earlier the correction is made, the longer the time during

which the jaws and the face can develop under normal conditions, and the better will be the esthetic result. Great improvement can be made, however, even after maturity has been reached.

The teeth will undoubtedly be retained longer if normal occlusion is established than they will if the condition is not corrected. There is no danger of loosening or losing the teeth if orthodontic treatment is properly conducted, although treatment by the inadequately prepared may bring about these undesirable results.

The treatment of such cases requires special knowledge and training not expected of the general practitioner of dentistry.

LIQUID WOOD SMOKE

To the Editor—In the August 10 issue of THE JOURNAL, under Queries and Minor Notes in answer to a Kentucky physician's inquiry, you referred to tests (allergic) including wood smoke. Will you kindly outline in detail for me the complete method of manufacturing an extract of smoke? I have often recognized the need of this extract among the others that I use but have not seen an account of its use or preparation. I follow Coca's methods of extraction, so if other solutions are used will you kindly give formulas? M A ENGLISH, M D Bainbridge, Ga

ANSWER.—The process of obtaining liquid wood smoke by distillation or burning wood is too difficult for the average laboratory. It is best to purchase liquid wood smoke, which is available everywhere on the open market and is usually produced from hickory wood for the purpose of curing meats.

DYSTROPHY OF THE NAILS

To the Editor—I have a case under my care in which there is alopecia and soft finger nails with a tendency to splinter. Under thyroid and calcium there is an improvement at intervals. Is there a relationship between the alopecia and the soft finger nails and, secondly, between them and the hypothyroidism, since this patient has a basal metabolic rate of -18? Does the temporary improvement depend on the change in dosage? Kindly omit name.

M D Pennsylvania

ANSWER.—The association of alopecia areata with coincident dystrophy of the nails has been reported by many writers. The etiologic basis for the two conditions may be quite variable and in some instances are related. In the case mentioned it is quite possible that there is an endocrine relationship, especially since improvement is noted on thyroid therapy. It is advisable to continue thyroid medication, with careful observation for any toxic evidence of excessive dosage. Calcium and viosterol may also be given, because of the nail involvement, along with the thyroid or in the intervals between the thyroid administration.

SCARLET FEVER STREPTOCOCCI

To the Editor—How many strains of streptococci have been known to cause scarlet fever? Does the commercial scarlet fever toxin protect against all these strains? J H A PECK M D St Francis Kan

ANSWER.—Two cultural and agglutinative types of hemolytic streptococci are known to have produced experimental scarlet fever in human volunteers.

The commercial scarlet fever toxin protects against all known strains of scarlet fever streptococci.

SCARLET FEVER IMMUNIZATION

To the Editor—In Queries and Minor Notes in THE JOURNAL July 20 page 222 Dr H A Wildman of Sterling Ill made the following inquiry:

I would appreciate information concerning the frequency, severity and duration of reactions to scarlatina immunization injections. Has there been any recent modification of toxin or the technic to reduce these reactions?

In your answer you stated that reactions occur in about 10 per cent following active immunization and that there has been no recent modification of the toxin or the technic. In this connection reference may be made to the following article: Melnick, Theodore. Prevention of Scarlet Fever. Methods to Minimize Reactions. Following Inoculations of the Dick Scarlet Fever Toxin (Arch Pediat 50 158 [March] 1933). In this investigation it was possible to reduce the frequency severity and duration of reactions.

At a meeting of the Section on Pediatrics at the Atlantic City session Dr J Norman Henry of Philadelphia in his presentation reported 38 per cent of reactions following scarlet fever active immunization treatments. This fact alone is of sufficient moment to cause physicians to be reluctant in the use of the toxin and therefore to seek methods to alleviate these obstacles.

THEODORE MELNICK M D Philadelphia

Medical Examinations and Licensure

COMING EXAMINATIONS

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY Written examination and review of case histories of Group B applicants will be held in various cities of the United States and Canada Dec. 7. Applications must be filed not later than Nov. 1. Sec, Dr Paul Titus 1015 Highland Bldg Pittsburgh (6)

AMERICAN BOARD OF OPHTHALMOLOGY The Cincinnati examination previously announced will not be held. The next examination will be given in St. Louis Nov. 18. Sec, Dr William H. Wilder 122 S. Michigan Ave. Chicago

AMERICAN BOARD OF ORTHOPAEDIC SURGERY St. Louis, Jan. Sec. Dr. Fremont A. Chandler 180 N. Michigan Ave. Chicago

Book Notices

Diseases of the Mouth and Their Treatment. A Text Book for Practitioners and Students of Medicine and Dentistry. By Hermann Prinz A.M. DDS M.D. Professor of Materia Medica and Therapeutica the Thomas W. Evans Museum and Dental Institute School of Dentistry University of Pennsylvania Philadelphia and Sigmund S. Greenbaum B.S. M.D. Associate Professor of Dermatology and Syphilology in the Graduate School of Medicine of the University of Pennsylvania. Cloth Price \$9 Pp. 602 with 298 illustrations Philadelphia Lea & Febiger 1935

Dr Prinz has been a leading figure in his field, and generations of students and practitioners have profited from his practical and stimulating instruction in the border zones between medicine and dentistry. This book is an adequate presentation of the fruits of his experience enhanced by collaboration with a competent dermatologist. The subject covered is generally inclusive for the diseases of the soft tissues of the oral cavity. Diseases of the bone and teeth are not discussed. In this respect this book is unique among textbooks published in the English language. The two chapters on the significance of the teeth with respect to digestive processes and on therapeutic suggestions contain material that is generally not available. In spite of the average excellence of the book, certain minor defects should be noted. There seems to be little excuse for the first two chapters on embryology and the anatomy and physiology of the oral cavity, as the treatment is necessarily brief and superficial. Many of the black and white illustrations are unsatisfactory either because of defects in reproduction or because of the poor quality of the originals. The same may be said of six of the full page colored plates. The book is highly recommended to students and practitioners of both medicine and dentistry.

La protéinémie et la pression osmotique des protéides. Recherches expérimentales et applications cliniques. Par Aniolne Codoune professeur agrégé à la Faculté de médecine d'Athènes. Préface du Professeur Ch. Achard. Clinique médicale de l'Hôpital Cochin et Institut de Biologie Clinique de l'Université de Paris. Paper. Price 38 francs Pp. 212 Paris Masson & Cie 1934

This monograph briefly discusses the literature on the origin and quantities of different proteins in the blood serum and changes in their concentrations and ratios in experimental and clinical studies. The author prefers the alcohol precipitation of proteins and their estimation by weighing to the refractometer method because the latter method gives too high results in the presence of increased lipins. Furthermore the alcohol method also enables one to estimate total lipins. In addition to total protein, a quantitative estimation of globulins was made. Thus the albumin globulin ratio was determined in each case. The author stresses the importance of this information concerning the differences in the amounts and ratios in different species and the same species in various diseases. The first half of the monograph describes his experiments on dogs and rabbits. From these studies he concludes that the most probable site of formation of serum proteins is the liver, that the thyroid may affect the blood serum-protein concentration through metabolic influences and that the stomach may assume an intermediary role. He shows that croton oil causes a rise in blood serum-protein concentration, that thirsting for days causes the reverse and that immunization also may cause some changes. In the second half, the clinical studies are reported. Although many observations are recorded with tremendous fluctuations in normal as well as in sick individuals, the author nevertheless considers many of the fluctuations in the pathologic cases as

of possible significance. Among the more clearly established cases of disturbed protein equilibrium in blood serum, one should mention the differences in the maternal and fetal blood, the hyperproteinemia in pneumonia, the irregular results in typhoid and paratyphoid, the normal results in meningeal tuberculosis, the possible significance of a change in the protein ratio in the prognosis of pulmonary tuberculosis, the hypoproteinemia (almost limited to the albumin) in nephritis not associated with lipoiduria, the fall in blood serum albumin in cirrhosis of the liver the rise in catarrhal jaundice, the hyperproteinemia in chronic arthritis of the nongouty type and the frequent change in the serum-protein ratio in various neoplasms, usually a marked fall in serum albumin in the advanced cases. Although gastric ulcers are not necessarily associated with a regular change in serum-protein content, nevertheless the injection of pepsin is followed by a rise in blood proteins and especially in the globulin fraction. Changes in lipin content, in albumin-lipin ratio, and in osmotic properties of the blood proteins are also considered in some cases as of possible importance in health and disease.

Names of Surgical Operations. Compiled and arranged by the Western Surgical Association through its Special Committee. Edited by Carl E. Black A.M. M.D. Cloth Price \$3 Pp. 102 St. Paul Minnesota Bruce Publishing Company, 1935

The result of the careful work of an able committee of surgeons with Dr Carl E. Black as editor, this list might be expected to justify the glowing tributes of the galaxy of surgeons who wrote the forewords. The book is at once a monument to the national medical cooperation that made it possible and an example of how far short of perfect first attempts of this kind are. It may be examined first in the light of its "basic principles" as set out in one of the forewords. The terms are to be "philologically correct" but "need lay no claim to description." Even granting that the two aims are compatible and that the sage remark in the introduction, "Words are the instruments for the communication of ideas," was meant for the reader and not the authors, the book will establish only superficial uniformity if the terms carry no exact accepted meaning.

The text may be examined also in the light of its usefulness. It goes even further than is necessary according to the "firm conviction" of one of its sponsors instead of being "as simple as possible" it is so simple that it cannot possibly serve as a guide to the useful record of operations. It is not to be supposed that records of operations are kept merely to comply with regulations, they are supposed to be used by surgeons for a definite purpose, namely, to measure the result of operative treatment and particularly to compare different surgical treatments of the same disease. The skin grafters have a decided advantage over the orthopedic and gastro-intestinal surgeons in this regard, just as the chiropodist is one of the few who can remove a specific type of diseased tissue, in contrast to the surgeon who, while he can excise a gastric ulcer, cannot do anything very specific with a neoplasm of the brain or even remove a wen. It is a needlessly sad commentary on the difficulties of brain surgery to permit the surgeon to look but scarcely to meddle. True, the "Meckel" may be excised ("philologically correctly") but not the "Gasserius." So far as can be discovered, any amputation but "interpelviabdominal" and "interscapulothoracic" will have to go unrecorded, although it would appear from the confusing format that not all permissible terms are printed in these arresting capitals.

Nor is the list "as practical as possible," for the record librarian will have difficulty deciding which pneumopexies to list under lung and which under pleura, and which decompressions fall under brain and which under skull, and "antrotomy" will have to be subdivided into "antrotomy, page 22," and "antrotomy, page 37." Indeed, half titles, such as "fistulectomy" (except 'recto-urethral,' singled out for special attention), "separation of adhesions," "decortication," "resection" and "skin flaps" are too 'simple' altogether for practical use either by the surgeon or by the record librarian. The only way to prevent ambiguity and misfiling is to phrase operative terminology in the most exact terms that the surgeon will use, not to rely on short cuts too vague even for those surgeons who have no thought for records.

The incoherence of the lists begins with the design. Even the profession that terms need have no exact meaning scarcely excuses the inclusion of fatty tissue or even ribs as "organs of locomotion." If it stopped even at the inclusion of the lymphatics under the glandular system, no harm would be done, but the listing of "clavicotomy," "costotomy" and "oblique (incision)" parallel to "osteotomy" makes recording difficult. Then there might well be instructions for combined procedures, and some explanation of the use of "laparotomy" and "craniotomy." These are only a few of the problems which the record librarian will face.

Although one cannot imagine that useful and instructive records can be kept in any hospital if the surgeon confines himself to these scanty and often ambiguous terms, there is no occasion to despair of this work. If the authors approach its revision with a clearer appreciation of the purpose of the record room and the educational value of exact and discriminative medical records, and with a better understanding of the modern technic of filing records and of the handicaps of untrained or partially trained record librarians in small hospitals, they will follow this edition with another which will bear to it something of the relation a motor car bears to the old-fashioned, high-wheeled, precarious—but simple—bicycle.

A Practical Manual of Diseases of the Chest. By Maurice Davidson M.A. M.D. F.R.C.P. Physician to the Brompton Hospital for Consumption and Diseases of the Chest. Cloth. Price \$14. Pp. 528 with 200 illustrations. New York and London: Oxford University Press, 1935.

This is a manual of diseases of the chest, not including the heart. It is intended for physicians, not medical students, who are interested in diseases of the lungs, pleura and mediastinum. Each chapter, followed by a bibliography of source material, is a good presentation of a single topic, according to the modern, largely English, conception of diseases of the chest. Covering the entire field of respiratory diseases as it does in one volume, it must treat individual diseases of the chest far too superficially to satisfy the requirements of a specialist in pulmonary diseases, only thirty pages being devoted to the entire subject of the pneumonias and but fifteen to the anatomy and physiology of the respiratory mechanism. The chief criticism of the book, therefore, is that it covers far too much ground and treats the subject matter too superficially to be of great value to those intending to take up diseases of the chest as a specialty. The book is well written and profusely illustrated by means of drawings and roentgenograms. It is purely clinical, many interesting and illustrative case reports are interspersed throughout the text, and considerable space is devoted to methods of management. Drug therapy occupies an undue prominence according to American standards. Three pages are given over to a discussion of drugs in the treatment of pneumonia and but four lines to the use of oxygen. As might be anticipated, the chapters on pulmonary tuberculosis, industrial respiratory diseases, bronchiectasis, diseases of the pleura, intrathoracic new growths and intrathoracic suppuration occupy the major portion of the work and, for the stated purpose of the book, are adequately and informingly handled.

Human Anatomy Double Dissection Method. By Dudley J. Morton, Associate Professor of Anatomy, College of Physicians and Surgeons, Columbia University. First Dissection, Second Dissection. In Two Volumes. Cloth. Price \$6 per set. Pp. 550 with illustrations. New York: Columbia University Press, 1934.

This is a practical manual for dissection combined with a notebook. It reports the result of a pedagogic experiment continued now for a period of six years. The time allotted to dissection in most medical colleges has been reduced to about half of that formerly available. Nevertheless the fundamental necessity of a good knowledge of gross anatomy remains, as does also the requirement by state boards that each student dissect one lateral half of a human body. Teachers are confronted with a condition in which so much of the time assigned is required by the mechanical work of dissection that too little remains for study of the part. Morton presents in this book a thoroughly worked-out plan by which two students are assigned to each part, one dissects, both study. Two dissections are made: first of muscles, bones, joints, viscera and larger structures, second of nerves, vessels and finer structures. Full directions for dissection and study are given for

each part—the students proceeding all together at equal pace—with which the lectures and the study of minute structure (histology) are coordinated. The book provides also on tables and blank pages a scheme for record of work done and observations made together with appropriate topics for discussion. The functional point of view is encouraged by a few appropriate questions and problems (e. g., muscles concerned in underhand bowling, shot putting, and so on). It is reported that it has worked well, that it is popular with the students, that they become well prepared for upper class work, and that they have done well on national and state board examinations. The idea of providing more time for study after dissections are made seems sound and timely. The experiment suggests the possibility that even more time for study might be secured if the students combined their efforts in one dissection instead of two.

Die Elektrokrdiographie und andere graphische Methoden in der Kreislaufdiagnostik. Von Professor Dr. Arthur Weber, Direktor des balneologischen Universitäts-Instituts Bad Nauheim. Second edition. Paper. Price 15.60 marks. Pp. 183 with 129 illustrations. Berlin: Julius Springer, 1935.

The author has brought the subject down to the present in this edition. The subject matter is simply presented and should be useful for those desiring a brief authoritative presentation of the graphic methods of studying heart action. The description of the principles of recording instruments employed is especially to be recommended as well as the section on the venous pulse. The author avoids polemic material and presents a purely objective account of the prevalent views and his own inclinations. The utility of the book for non-German readers is greatly lessened because the instruments described are limited for the most part to those of German manufacture, which are little used in this country. However, the excellent discussion of principles of these instruments is applicable to all similar apparatus. The author's endeavor to present practical details in using instruments, based on his own experience, is a particularly useful approach. It is unfortunate that the illustrations fall far short of the text and often, particularly in the case of heart sounds and murmurs, fail to illustrate the text. Perhaps the author also overemphasizes the utility of pulse and heart sound records for practical diagnostic problems. Nevertheless the monograph will repay the reader who carefully peruses it, especially if he has had some experience in the field. Throughout he will find hints useful in improving his technic and interpretations.

The 1934 Year Book of Neurology, Psychiatry and Endocrinology. Neurology. Edited by Hans H. Reese, M.D., Professor of Neurology and Psychiatry, University of Wisconsin Medical School. Psychiatry. Edited by Harry A. Paskind, M.D., Assistant Professor of Nervous and Mental Diseases, Northwestern University Medical School. Endocrinology. Edited by Elmer L. Sevringhaus, M.D., Associate Professor of Medicine, University of Wisconsin Medical School. Cloth. Price \$3. Pp. 782 with 60 illustrations. Chicago: The Year Book Publishers, Inc., 1935.

This volume of the Year Book appears for the first time since 1918 without the authorship of Dr. Peter Bassoe. The publishers have written a foreword expressing their appreciation of his great service in editing the Year Book over this long period with the utmost intelligence and conscientiousness. The labors of Dr. Bassoe have over these years saved the neurologist and psychiatrist much effort in keeping up with the important literature of this country and abroad. Dr. Bassoe has had the foresight to include the literature on endocrinology in his previous volumes. This year Dr. Sevringhaus has the editorship of the section on endocrinology and has not alone abstracted the current literature for the year but also given a useful outline of the current ideas of the interrelationships of the glands of internal secretion. This section with its critical selections and wise comments is valuable to any one desiring to keep up with the rapid progress in this field. Dr. Paskind has assumed the editorship of the section on psychiatry, and one finds a great improvement in that portion of the Year Book. The work of the various schools of psychiatry are impartially abstracted. The most valuable contributions of the year are adequately reported. There is, however, some slighting of the field of psychoanalysis, particularly in the work that is closely related to the problems of internal medicine. The section on neurology is edited for the first time by Dr. Hans

Reese, who has thoroughly reviewed the field of organic diseases. The choice of articles and the method of abstraction in this section are commended except perhaps for too uncritical acceptance of William F. Petersen's studies on meteorological, seasonal and geographic correlations with nervous and mental phenomena.

Les névroses tachycardiques. Par L. Gallavardin. médecin des hôpitaux de Lyon et A. Tourniaire. Paper. Price 17 francs. Pp. 120 with 24 illustrations. Paris: Masson & Cie. 1935.

This is an excellent condensed summary of the condition of "irritable heart." It considers the subject in eight divisions: historical, symptomatology, etiology, pathogenesis, clinical forms, diagnosis, prognosis and treatment. The authors not only include a brief and clear outline of the literature but present some of their own work on this subject. There is perhaps too much detail in the section on symptoms, especially in regard to laboratory procedures. The last five sections are especially succinct, and the evidence that the condition is not myocardial in origin and not hyperthyroid disease is well assembled. The authors stress the fact that while the disease persists and may always flare up, it does not lead to the sequelae seen in organic disease. They point out that reeducation by graded exercises of various sorts is especially desirable. There is included an extensive bibliography of the pertinent literature covering almost 300 references. The book is recommended for a quick survey of this interesting field.

Medicolegal

Malpractice Drainage Tube Lost in Patient's Chest, Standard of Skill by Which Physician Is Judged—The defendant, a physician, was in charge of a county tuberculosis hospital in which the plaintiff's husband was a patient. He had been operated on, and, according to the report of the case, "a sinus had formed between the pleural cavity and the outside." To drain this so-called sinus the defendant inserted a catheter between the ribs, but the catheter bothered the patient and on March 16 the defendant replaced it by a tube three or four inches long. He anchored this tube by wrapping adhesive tape around it, with the ends stuck to the chest. The next morning however the tube was missing. A physician summoned by the plaintiff, the patient's wife, at the request of the defendant, agreed with the defendant that a piece of a rib ought to be removed "to permit better drainage." The operation was performed March 19 by the consultant physician, in the defendant's presence. The patient died a few hours later. An autopsy disclosed the lost tube lodged along the spine. The plaintiff, as special administratrix of her husband's estate, sued the physician defendant and from a judgment in her favor he appealed to the Supreme Court of Michigan.

An outstanding element in the plaintiff's complaint was that the defendant was negligent in not using the safety pin method for fastening the short drainage tube when he used it. The defendant testified however that he had always used the method he employed in the present case and never before had lost a tube. Other physicians, testifying for the defense, stated that the method used by the defendant was in accord with proper practice, although most or all of them generally used a safety pin. Medical witnesses for the plaintiff, however, testified that the customary practice of the community and in like communities was to use a safety pin and while some said they had never seen any other method used they did not say that the method employed by the defendant was not recognized as proper practice. A medical witness for the plaintiff was permitted to testify that he had seen the safety pin method used at the Mayo Clinic and the Augustana Hospital but the admission of this evidence said the Supreme Court was error. Defendant was not to be charged with the peculiar skill or methods of practice used in famous institutions nor was his treatment to be judged by the treatment that another physician would have used under the circumstances. The rule is firmly established that the defendant was bound to use the degree of diligence and skill which is ordinarily possessed by the average members of the profession in similar localities. Where there is an oppor-

tunity for choice, a physician is not guilty of negligence in using a method recognized as good practice, even though all his local contemporaries may employ another method.

The plaintiff charged that the operation was unnecessary to the patient's welfare and that its purpose was in fact to recover the tube, that the operation was negligently performed, and that delay and shock to the patient were caused by the surgeons, at the defendant's request, exploring the chest with their fingers to locate the tube. All the medical witnesses agreed, however, that the tube should be removed. None felt that it was immediately dangerous. Some thought no exploration for the recovery of the tube should have been made during the operation and that it should have been left for later treatment. The defendant contended that he was not responsible for negligence in the operation because the operating surgeon was in charge of it. On the plaintiff's theory that the operation was performed for the sole purpose of finding the tube and not by way of proper treatment and was done without the consent of the deceased the defendant, in the judgment of the Supreme Court would be liable for the manner of its performance, because he advised it, participated in a medical way, was present and requested that exploration be made to find the tube.

The defendant complained because the plaintiff was allowed to testify that she did not discover that the operation was to be done or had been done until after it had been completed. Her consent to the operation was not necessary, said the court, because her husband was able to give his own consent. The failure of the defendant to notify her that an operation was to be performed, however, particularly in view of the inconclusive claim that the consent of the deceased had been obtained, was competent evidence in support of the plaintiff's claim that the operation was concealed from the interested parties and was done for the purpose of finding the tube.

For the reasons stated, the judgment of the trial court was reversed and a new trial ordered.—*Rytkonen v. Lojano (Mich.)*, 257 N. W. 703.

Malpractice Liability of Consultant—The physician-defendant Ramsey, a general practitioner, was called to attend the plaintiff who had broken his leg two days previously. The next day he returned with Dr. Dolan, a specialist in surgery, and the two put the leg in a cast. Dr. Dolan never saw the patient again. Apparently, no roentgenogram was made during Dr. Ramsey's attendance, and the cast was still on when he discontinued his services. Then another physician was summoned, a roentgenogram was made, and the patient was removed to a hospital. The outcome of the case was unfavorable. The patient sued both Dr. Ramsey and Dr. Dolan. The jury returned a verdict in favor of Dr. Ramsey, and the trial court directed a verdict in favor of Dr. Dolan. The patient appealed to the Supreme Judicial Court of Massachusetts.

The patient-plaintiff contended that the jury could have found Dr. Dolan, the consulting surgeon, negligent although he saw the plaintiff but once and then in company with the attending physician. Dr. Dolan's liability, if there is any, said the court, must be determined on the basis of his conduct during his one visit.

No evidence was offered to show that Dr. Dolan did not have proper professional skill or use such skill, or that he was negligent in treating the patient at home. There was no evidence on which to base any liability on Dr. Dolan's part for the treatment administered by Dr. Ramsey subsequent to Dr. Dolan's visit except as his giving temporary treatment might impose on him the duty to advise with respect to future treatment. The fact that Dr. Dolan did not advise the patient that the cast that was applied was only temporary and that a later reduction of the fracture would be necessary could not be said to show lack of skill, inasmuch as Dr. Dolan, the consulting physician, was dealing with Dr. Ramsey, the physician in charge of the case, who was present when the temporary treatment was given. Dr. Dolan could reasonably rely on Dr. Ramsey's knowing that the cast was only temporary and that a later reduction of the fracture would be necessary, without his being told and on such knowledge being adequate notice to the plaintiff of future requirements of the case. Nothing in the evidence supported the view that Dr. Dolan did not use proper skill in giving temporary treatment without first having

a roentgenogram made, and the evidence did not show that Dr Dolan failed to use proper skill with respect to advice concerning the making of a roentgenogram and the treatment of the patient in a hospital. The patient's own testimony showed that he knew that both Dr Dolan and Dr Ramsey contemplated that a roentgenogram should be made. Dr Dolan's own testimony that he told Dr Ramsey to get the patient into a hospital and to get x-rays was properly admitted.

Dr Ramsey, the attending physician, was not liable for any act or omission by Dr Dolan, the consultant, in his treatment of the patient. There was no evidence to show that the selection of Dr Dolan was improper or that in treating the patient Dr Dolan acted as the agent or servant of Dr Ramsey or acted under his direction or control.

The patient-plaintiff apparently complained of instructions given the jury concerning the duty of the attending physician to transport his patient to a place where roentgenograms could be made. It was no part of the ordinary duty of Dr Ramsey, as an attending physician, to transport his patient to a place where roentgenograms could be made. If he undertook to do so as an incident of his treatment, he did not fail in his duty as a physician if he withdrew from his undertaking after giving reasonable notice of his proposed withdrawal. Nothing in the evidence disclosed any special contract that imposed on Dr Ramsey any greater duty to transport the plaintiff than was described in the charge to the jury by the trial court. Furthermore, if failure to have a roentgenogram made was due to the patient's conduct after he had been advised of the necessity for a roentgenogram, it was not malpractice for Dr Ramsey to continue to treat the plaintiff without a roentgenogram.

All exceptions taken by the patient-plaintiff to the judgment of the trial court in favor of Dr Ramsey and Dr Dolan were overruled—*Shannon v Ramsey, Some v Dolan (Mass)*, 193 N E 235.

Insurance, Accident "Local or Constitutional Disease" and "Attended by a Physician" Construed—The defendant insurance company promised to pay certain benefits if Rubin's death resulted "directly, independently and exclusively of all other causes from accidental bodily injuries." Rubin was killed by an automobile. The trial court gave judgment against the insurance company, which then appealed to the United States circuit court of appeals, ninth district.

The policy provided that "the falsity of any statement in the application materially affecting either the acceptance of the risk or the hazard assumed hereunder, or made with intent to deceive, shall bar all right of recovery under this policy." In his application, Rubin stated that during the past five years he had not had any "local or constitutional disease" and had not been "attended by any physician." During this period he had been examined by an oculist and found to be suffering from acute astigmatism and nearsightedness, and glasses were prescribed. The insurance company contended that Rubin had thus made false representations as to his physical condition, which barred recovery under the policy. Minor physical defects and ailments, said the circuit court of appeals do not come within the scope of questions and answers such as those found in the application under discussion. In *Poole v Grand Circle, W O W* 18 Calif App 457, 123 P 349 the court said:

Illness as used means a disease or ailment of such a character as to affect the general soundness and healthfulness of the system and not a mere temporary indisposition which does not tend to undermine and weaken the constitution of the insured. A reasonable construction of the question [consulting a physician] implies that it should be interpreted as relating to a consultation as to some disease or illness with which the applicant was or had been afflicted not to some feeling of trivial discomfort or temporary indisposition not affecting the general health.

The circuit court of appeals concluded that nearsightedness and astigmatism, which ordinarily at least do not affect the general health, were not local or constitutional diseases, and that Rubin had not been "attended by a physician" during the period in question. Moreover, continued the court, had the statements in the application been untrue, there was no evidence that they

were made with the intent to deceive the insurer, and the insured's defective vision did not materially affect the hazards assumed by the insurance company under the policy.

The judgment in favor of the beneficiaries was accordingly affirmed—*Ocean Accident & Guaranty Corporation Ltd, v Rubin*, 73 F (2d) 157.

Insurance, Accident Death from Starvation Due to Insanity Following Fall—The defendant insurance company promised to pay certain benefits if Watkins' death resulted "directly and exclusively of all other causes, from bodily injuries sustained solely through external, violent and accidental means." Watkins, a locomotive engineer, fell from his seat in the engine cab, receiving a scalp wound and concussion of the brain. He became insane, refused to eat and died of starvation three months later. The beneficiary obtained a judgment against the insurance company, which appealed to the Court of Appeals of Kentucky. The insurance company contended that a provision of the policy, which provided that it did not cover "injuries, fatal or non-fatal, sustained by the insured which shall result wholly or partly from disease, sickness or medical or surgical treatment therefor," barred recovery, because the original or primary cause of Watkins' injuries was disease. But, said the court, there was no evidence to show that Watkins had any disease prior to his injury, and, conceding that his fall was due to some disease or infirmity, his case falls within the well settled rule that a fall or other act resulting in an injury, though superinduced by disease or bodily infirmities, is nevertheless an accident within the meaning of the policy, if the injury is the direct result of the fall or other act and not a direct result of the disease. *Fidelity & Casualty Co v Cooper*, 137 Ky 544, 126 S W 111 and *Clark v Iowa State Traveling Men's Ass'n*, 156 Iowa 201, 135 N W 1114. The judgment in favor of the beneficiary was accordingly affirmed—*Provident Life & Accident Ins Co v Watkins (Ky)*, 76 S W (2d) 889.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American Journal of Anatomy, Philadelphia

57:1204 (July 15) 1935

- Significance of Lymphoid Nodule. H. E. Jordan. University Va.—p. 1.
Changes in Reproductive Organs of Ewe with Some Data Bearing on Their Control. H. H. Cole and R. F. Miller. Davis Calif.—p. 39.
Studies on Endocrine Glands of Frizzle Fowl. W. Landauer. Storrs Conn., and Sophie D. Aberle. Baltimore.—p. 99.
Inervation of Thyroid Gland. III. Distribution and Termination of Nerve Fibers in the Dog. J. F. Nonidez. Ithaca N. Y.—p. 135.
Development of Palatine Tonsil (Cat). A. J. Ramsay. Ithaca N. Y.—p. 171.

American Journal of Diseases of Children, Chicago

50:1308 (July) 1935

- Trend of Pediatric Education and Practice. President's Address. B. S. Veeder. St. Louis.—p. 1.
Antirachitic Effects of Radiation from Different Sources. Comparative Study. C. I. Reed and A. Bachem. Chicago.—p. 11.
Effect of Iron and Copper Therapy on Hemoglobin Content of Blood of Infants. C. A. Elvehjem, A. Siemers and Dorothy Reed. Mendenhall, Madison Wis.—p. 28.
*Filamented Nonfilamented Cell Count in Appendicitis in Children. S. D. Mills. Rochester Minn.—p. 36.
Absorption of Undigested Proteins in Human Beings. IV. Absorption of Unaltered Egg Protein in Infants and in Children. S. J. Wilson and M. Walzer. Brooklyn.—p. 49.
*Clinical Comparison of Antirachitic Value of Irradiated Yeast and of Cod Liver Oil. E. L. Compere, Thelma E. Porter and Lydia J. Roberts. Chicago.—p. 55.
State of Calcium in Fluids of Body. II. Calcium in Blood in Rickets. E. L. Compere, F. C. McLean and A. B. Hastings. Chicago.—p. 77.
*Hematogenous Tuberculosis in Children. Edith M. Lincoln, New York.—p. 84.
Comparative Values of Cutaneous, Percutaneous and Intracutaneous Tuberculin Tests in Children. Special Reference to Sensitiveness of Plaster Test. G. Anzén. Stockholm Sweden.—p. 104.
Late Infantile Amaurotic Idiocy with Marked Cerebral Atrophy. Clinical and Anatomic Report of Case. R. Richter and A. H. Parmelee, Chicago.—p. 111.
Influence of Viosterol and Parathyroid Extract on Mineral Metabolism in Osteogenesis Imperfecta. A. E. Hansen. Minneapolis.—p. 132.

Appendicitis in Children.—From an analysis of forty-one cases of appendicitis among children Mills places the aids in diagnosis in the order of their reliability (1) an increase in the total leukocyte count, (2) an increase in the number of neutrophils and (3) an increase in the number of nonfilamented neutrophils with a nonfilamented-filamented cell ratio exceeding 1. In the Schilling count the presence of very immature leukocytes in the course of a case of appendicitis is important evidence of the demand being made on the bone marrow. The nonfilamented cell count provides no means of showing how immature the nonfilamented forms may be. The nonfilamented cell count may increase in advance of the rise in total leukocytes or neutrophils. An increase in any or all of these forms should warn one of the possibility of extension of the infection. In acute appendicitis, an initial high nonfilamented cell count means that the outlook is bad. With the total percentage of neutrophils higher than 90 and with less than 10 per cent of these filamented forms the prognosis is grave. A falling nonfilamented cell count or a nonfilamented-filamented cell ratio of less than 1 is a good sign, as are also the reappearance of eosinophils and monocytes and the disappearance of neutrophils of the toxic type from the peripheral circulation. The nonfilamented cell count is of value in the diagnosis of appendicitis, since it parallels the neutrophil count during the course of the infection. The nonfilamented cell count is not reliable alone in a sufficient number of cases to be of the same diagnostic worth as the total leukocyte count and the percentage of neutrophils.

Antirachitic Value of Irradiated Yeast and of Cod Liver Oil.—Compere and his associates found that irradiated dry yeast is an effective therapeutic antirachitic agent when given to children in sufficient quantities. The minimal amount of irradiated dry yeast used in the experiment that seemed to effect a cure was 1.25 Gm daily. This contained 6,755 International or U. S. P. revised units of vitamin D. On the basis of roentgenographic evidence it was necessary to give from 11 to 33 times as many rat units of vitamin D in the form of irradiated yeast as in the form of cod liver oil to bring about a comparable degree of improvement in rickets in children.

Hematogenous Tuberculosis in Children.—Lincoln advances the theory that hematogenous dissemination of tuberculosis follows the establishment of the primary complex in the majority of cases. Clinical, bacteriologic and pathologic proof exists that this may occur. Four groups of cases ranging from instances of the marked forms of protracted disseminated hematogenous tuberculosis to those of occult bacillema are described, and typical clinical cases are presented. She is certain that obvious hematogenous disseminations in the lungs, such as those which occur in the marked protracted cases, may break down and exactly simulate the clinical picture of chronic ulcerative tuberculosis. If these small foci of hematogenous origin prove to be a frequent source of the subapical infiltration of chronic organic phthisis, another link in the chain of knowledge concerning the pathogenesis of pulmonary tuberculosis will be furnished. Exogenous reinfection as a cause of apical tuberculosis cannot be discarded. A recent heavy exposure to tuberculosis is often mentioned in the history of adolescent boys and girls and young adults with subapical infiltrations. But it may be that exogenous reinfection causes an activation of older hematogenous lesions, which subsequently break down and lead to bronchogenic extension.

Mineral Metabolism in Osteogenesis Imperfecta.—Hansen's study of two cases confirms the view that one of the characteristic abnormalities in osteogenesis imperfecta is a deficiency in the retention of calcium and phosphorus under conditions that favor retention in normal persons. The evidence regarding a similar deficiency in magnesium metabolism is suggestive but not conclusive. Except for the tendency to excrete an abnormally large proportion of the calcium and phosphorus ingested, no evidence of hyperfunction of the parathyroids has been obtained. The finding of normal values for these elements in the blood and of essentially normal parathyroid bodies in the one patient who was examined at necropsy suggests at least that this cannot be the chief etiologic factor. The clinical picture, including the changes in the bones shown by roentgen examination, is not that commonly seen in patients with acquired hyperparathyroidism. The deficiency in the phosphatase activity of the periosteal and subperiosteal tissue appears to offer a more satisfactory lead for future investigation. The responses of patients with osteogenesis imperfecta to parathyroid extract and to viosterol in various dosages are apparently not significantly different from those of normal persons. The fact that these agents only aggravate the existing abnormal tendency proves with certainty that hypoparathyroidism is not a feature of the pathogenesis and that the deficiency is in no way similar to that occurring in patients with rickets. The data regarding the protein metabolism and all the features of the mineral exchanges of the body other than those mentioned indicate that the defect in metabolism in patients with osteogenesis imperfecta is confined fairly strictly to the mechanism of osseous growth and development.

Longitudinal Muscles in Adrenal Veins—Zeckwer proposes a theory to explain the part which the longitudinal muscles in the adrenal vein in man play in controlling the discharge of epinephrine. She suggests that under sympathetic stimulation these muscles relax and widen the lumen and that under parasympathetic stimulation they contract and, by their consequent thickening, occlude the lumen. In the material obtained in a series of necropsies, it was observed that these muscles developed with age. It is suggested that the hypertrophy of these muscles may be a protective phenomenon, checking the discharge of epinephrine in hypertensive patients.

Hormone Origin of Endometrioma—The hypothesis submitted by Witherspoon is that the fundamental igniting cause of endometrioma has its origin in the excessive stimulation of the aberrant tissue by the ovarian follicular hormone. That the action of this hormone is not confined to the uterine endometrium alone, as demonstrated by the endometrial changes during the normal menstrual cycle, but influences the genital tract as a whole is easily proved. When this hormone action on the endometrium is abnormal, however, causing endometrial hyperplasia, it is equally abnormal in its action on ectopic endometrial tissue and causes, by means of cellular metaplasia of the potential serosal cells or by tumor proliferation of an aberrant endometrial implant, the formation of an endometrioma. The morphologic and functional characteristics of an endometrioma and of the uterine endometrium are similar, the integrity and function of the endometrioma are dependent on the presence of active ovarian tissue, since castration causes regression of the tumor, the endometrioma presents decidua reaction during pregnancy, it undergoes the phases of the menstrual cycle, changes dependent on the ovarian hormones, and, as proved by Gleave in rabbits, the presence of the estrogenic principle is essential for the maintenance of the lesion. Since the ovarian follicular hormone is the cause of endometrial hyperplasia and since the histologic structure of the endometrioma and that of the uterine endometrium are similar, it is logical to deduce that the igniting factor of endometrioma, which brings about the cellular metaplasia or the proliferation of the endometrial implant, is the estrogenic principle. That such is the case is all the more firmly established by the fact that in many instances the endometrioma presents hyperplasia which is typical histologically of endometrial hyperplasia and also by the high incidence of the association of endometrioma with uterine endometrial hyperplasia. The frequent finding of all the features of endometrial hyperplasia in an endometrioma, accompanied with similar changes in the uterine mucosa, indicates that the endometrioma can be caused only by the factor which determines the mucosal changes—the ovarian follicular hormone. It seems logical to deduce that the multiple follicular

cysts of the ovaries, in the absence of corpora lutea, which cause, through the action of the estrogenic principle, endometrial, uterine and mammary hyperplasia or hypertrophy, likewise cause endometriomas, uterine fibroids and mammary fibro-adenomas. There are two clinical features—functional uterine hemorrhage and sterility—that are associated with endometrioma, and their occurrence is explainable by the hypothesis stated.

Aneurysm of Internal Carotid Artery—Saphir describes three instances of encephalomalacia and cerebral hemorrhage, the causes of which could not be determined until the internal carotid arteries were completely dissected and severe occluding lesions found in them. These lesions were thought to have been the etiologic factor in the lesions of the brain. He believes that in every instance of encephalomalacia and cerebral hemorrhage the internal carotid and vertebral arteries should be examined throughout their course in order to locate morphologically demonstrable causes of the lesions of the brain. Three procedures should be observed in the explanation of these lesions in the absence of occlusions of the vessels at the base of the brain or of their branches. 1 The internal carotid and vertebral arteries should be examined throughout their course for occluding lesions. 2 The state of the circle of Willis should be studied with particular reference to congenital anomalies that may have caused an interruption of its continuity. 3 Morphologic evidence of cardiac failure should be looked for, such as coronary arteriosclerosis with resultant myocardial fibrosis and chronic passive hyperemia of the various organs. All these anatomic lesions should be searched for and carefully evaluated or eliminated before the pathologist resorts to an explanation based primarily on functional disturbances. In the three instances reported, occlusions of the internal carotid arteries were found in the region of the cavernous sinus and within the carotid canal of the temporal bone. The occlusions were the result of the tortuosity of the arteriosclerotic vessels with inversion of the walls and formation of bends or kinks. If Jores' classification is used, such a lesion of the artery is referred to as serpentine aneurysm.

Treatment of Asthma—The Pottengers state that asthma is a condition in which all systems of vegetative control of cellular activity, nervous, endocrine and electrolytic, may be in imbalance. Adrenal extracts have long been used in the treatment of allergic manifestations. One Gm. of raw adrenal is therapeutically equivalent to 100 Gm. of extract. The authors treated fifty asthmatic patients with epinephrine in oral doses of one-sixteenth grain (0.004 Gm.) three times daily. The patients received from 0.5 to 1 cc. of adrenal cortex extract in orange juice two or three times a day after meals. Sodium chloride was given as table salt in doses of from 3 to 6 Gm. in 8 ounces (240 cc.) of water one-half hour before meals. The sodium chloride by mouth produces euphoria, improved intestinal function, the stools containing a larger amount of moisture though formed, some diminution of the frequency of asthmatic attacks and fortification of the effect of the cortical extract. In no case has salt alone controlled asthma, but the combined use of salt and adrenal cortex extract has lessened the amount of extract necessary to relieve the patient. In nineteen children treated in the clinic and in nine adults insti-

tionalized, the asthma was considerably relieved. The asthma was precipitated again in many cases by colds or other acute infections or overexertion. In no case did the recurrence prove refractory to subsequent treatment. Of the cases reported, the results in all but two were satisfactory. These two patients were not able to submit to a program of rest, which is so essential to the relief of their condition, but they experienced a feeling of well being, although neither was completely freed from the attacks.

Tuberculous Bacillæmia and Dementia *Praecox*.—Kopeloff and his collaborators submitted to Loewenstein triplicate samples of blood from patients presenting mental and physical diseases as well as from control subjects, as individual specimens of unknown origin. Among fifty-four controls, five positive macroscopic cultures of *Mycobacterium tuberculosis* were reported, coming from healthy young males in whom there had been no demonstrable tuberculous infection. Macroscopic cultures of *Mycobacterium tuberculosis* did not occur in twenty-five cases of active pulmonary tuberculosis or in twenty-four cases of eye infection, two of which were diagnosed tuberculous retinitis. Twenty-seven positives were reported in ninety-six cases of dementia *praecox* and seven positives in nineteen miscellaneous psychoses and neuroses. These results contradict Loewenstein's previous claims of a high incidence of positive blood cultures of *Mycobacterium tuberculosis* in febrile pulmonary tuberculosis and in dementia *praecox* and a complete absence of positive observations in controls. By rigidly following Loewenstein's technic on 375 blood samples from the same patients the authors were unable in any instance to obtain cultures of *Mycobacterium tuberculosis*. Of eight spinal fluid specimens from suspected cases of tuberculous meningitis, six yielded positive cultures of *Mycobacterium tuberculosis* on Loewenstein medium in sixteen twenty-three, twenty-seven, forty-five, fifty-two and 125 days, respectively. Loewenstein's results and the authors failure to obtain any positive blood cultures indicate that there is no justification for further study of patients with dementia *praecox* by his methods.

Influenza Vaccine in Treatment of Chronic Encephalitis.—Abramson and Victor treated 125 patients presenting chronic encephalitis with injections of the soluble antigen of the Hammett strain of the Pfeiffer bacillus. Treatment in most cases consisted of a series of weekly injections of 0.5 cc. of the antigen. In some cases the lack of any improvement and the hardship suffered by the patient by the withdrawal of all other medication induced the authors to cease using this form of treatment after one or two months, but the majority of the patients continued to receive the antigen for from twelve to eighteen months. Bedridden patients universally failed to receive any benefit from this or from any other form of treatment. At the end of treatment with the antigen over a period of eighteen months, no persistent improvement was observed in any of the patients which could be attributed to this form of treatment. Occasionally some of the patients thought they could walk with less rigidity but soon relapsed into their former state while continuing to receive the antigen. These results are in marked contrast to those obtained by Stewart and Evans, who reported improvement in 78 per cent of the patients treated by the same method. The authors conclude that there is no relationship between chronic encephalitis and the Pfeiffer bacillus. If this bacillus is the etiologic agent of influenza, no direct relationship exists between influenza and epidemic encephalitis.

Detecting Tubercle Bacilli in Blood Stream.—Mishulow and her collaborators studied ninety-eight specimens of blood from sixty-three tuberculous patients and two specimens from a patient with actinomycosis of the jaw to determine whether the hemoglobin in the human blood interferes with the growth of tubercle bacilli, as stated by Loewenstein. The specimens were divided into two equal parts, one part of the blood was cultured on Bordet-Gengou and on congo red egg mediums without any treatment, and the other part was treated according to Loewenstein's method. It was found that the whole blood gave better results than the portion treated by the Loewenstein method. There were three macroscopically positive cultures

on the whole blood and only two on the Löwenstein cultures. In one additional Löwenstein culture, several small clumps of acid-fast bacilli were found microscopically when the surfaces of the tubes were scraped, but subcultures and guinea-pigs that were inoculated with these scrapings gave negative results. Tubercle bacilli were found in only four of the forty-six patients with advanced pulmonary tuberculosis, a large number of whom were critically ill, and two of the four patients who gave positive blood cultures died soon after the last cultures were made. All other cases in this series gave negative results. In two instances, saprophytic acid-fast bacilli were found in the cultures. This shows the need for identifying carefully the cultures obtained, especially if they are nontypical on colony morphology. It appears that the hemoglobin in human blood is not inhibitory to the growth of tubercle bacilli, since cultures of whole citrated blood gave better results than blood that was treated by Löwenstein's method to remove the hemoglobin. Culturing whole blood has the particular advantage over Löwenstein's method of culture in that it requires no preliminary treatment. The use of plates instead of tubes as recommended by Löwenstein has the advantage of a large surface on which the specimen is well distributed, and a slight contamination seldom overgrows the culture.

- *Acute Pancreatitis E H Risley Waterville.—p 110
- Pain H E MacDonald, Portland.—p 116

Acute Pancreatitis—Risley states that acute pancreatitis is not an uncommon disease. Its incidence is estimated to be around 1 per cent of acute abdominal emergencies. Obstruction to and backing up of bile and pancreatic ferments into the pancreatic ducts are the probable etiologic factors producing the condition. The onset is usually sudden, occurring at the height of digestion in subjects previously well. Pain out of all proportion to the physical signs is the predominating symptom. Shock is generally always present and is marked

Prolonged nausea and vomiting with absence of marked abdominal signs at the onset are also common. In addition to these symptoms the author finds acute upper abdominal tenderness, with distention confined to the upper quadrants. Slate blue discolorations of the abdomen and thighs, a rise in pulse, temperature and leukocyte count, glycosuria and a high blood sugar together with high amylase values present the unquestionable picture of fulminating pancreatitis. Operation should never be done in the presence of the initial shock and, if delayed from four to eight days, seems to give the best results. Mortality is high, varying between 50 and 90 per cent. Complications are frequent and convalescence is protracted.

Liver Deaths Following Surgery of Gallbladder—Hewitt discusses the literature on the subject and presents two case histories. The patients were in good physical condition for the operation, which required a comparatively short time, and no complications arose during the operation. Drainage was done in both cases. There was no hemorrhage, peritonitis or immediate shock after operation. In each case a high temperature developed, with rapid pulse, oliguria, anuria, delirium, coma and death within forty-eight hours. Necropsy was not permitted in either case, and postoperative life was so brief that little time remained for clinical observation or laboratory tests. The author advises in all preoperative cases that the function of the liver be determined by tests already known, that large quantities of dextrose be administered without the use of insulin, and that dehydration be combated by the use of known quantities of fluid. Therapy should be controlled by repeated chemical analyses of the blood. Blood chlorides should also be estimated and, if as low as 250, physiologic solution of sodium chloride should be given intravenously. Anesthetics that produce anesthesia by rectal or colonic administration carry with them the possibility of increased insult to the functioning of the liver. Nitrous oxide gas with the addition of small quantities of ether combined with local anesthesia is the safest type of anesthesia. Blood transfusion and the intravenous administration of calcium chloride are at times valuable in the preparation of patients for operation.

Interstitial Hernia—Beigler states that interstitial hernias are more common than the literature reports but that they are not recognized as such. He refers to a patient operated on for bilateral indirect inguinal hernia. On the left side there was a typical indirect inguinal hernia, but on the right side a double sac was found to be protruding through all the muscular layers as far as the external oblique fascia. The sac was isolated and separated from its adjacent structures. Both hernias were repaired. The patient made an uneventful postoperative recovery. Interstitial hernia may be defined as any hernia which in the course of its development spreads out in the planes of interstices of the abdominal wall. There are three types of interstitial hernias described. The peritoneal type indicates that the sac lies between the peritoneum and the transversalis fascia. The position of the sac most frequently is between the internal inguinal ring and the anterior superior iliac spine. The sac may follow the direction of the inguinal canal into the scrotum or it may go backward to occupy the inner part of the iliac fossa. In the inguinal interstitial type the sac may be

located between the transversalis muscle and the transversalis fascia, between the transversalis muscle and the internal oblique muscle or between the internal and external oblique muscles. In the inguinal superficial type the sac is found between the aponeurosis of the external oblique and the superficial fascia. The sac, regardless of type, is usually bilocular, one sac being located in the inguinal canal or scrotum, the other in any of the locations of interstitial hernia. Undescended testis usually accompanies the hernia. Some form of obstruction is the most common etiologic agent. Early diagnosis is essential because of the increased possibility of strangulation.

Total Thyroidectomy for Heart Disease—Cutler has removed sixty-four normal thyroids, some for diabetes and for peripheral vascular disease in addition to cardiac disorders. Two immediate deaths occurred in elderly men with failing hypertensive heart disease, whose myocardial reserve was insufficient to stand any excess burden and whose hearts steadily failed following the operation. Two immediate deaths in patients having angina pectoris were due to classic attacks of coronary closure on the first and second postoperative day, similar to those which had occurred previously in these patients. Two of the patients died elsewhere during operations for gallstones. There were no particular postoperative complications, though mild signs of parathyroid tetany occurred in five cases and there was injury to the recurrent laryngeal nerve in four. Visualization of the recurrent nerve is the only essential feature of the operation and this can best be done from the side on which it lies. Considering that all cases were of the most serious type, the results are satisfactory. Patients presenting heart failure were all bedfast and unrelieved by modern medical means previous to thyroidectomy, while those with angina pectoris had angina decubitus. Many in the two groups were restored to an active and comfortable life. The author states that total thyroidectomy does not modify the output of epinephrine, but the substance produced is less effective under the conditions imposed by total thyroidectomy. Worry, anxiety and psychic disturbances of any type may produce a large discharge of epinephrine, and this must be considered in the explanation of anginal pain. Thyroidectomy may produce its effect by interfering with the sensitivity of the vasomotor apparatus to epinephrine, as already indicated by the studies of skin temperature following total thyroidectomy, in which greater vasodilator ability is found even in myxedematous people. The author concludes that there is an interrelationship between the adrenal and the thyroid which is of major importance in the symptom complex of angina pectoris.

Recurrence of Benign Obstructing Prostates After Prostatectomy—Chute refers to two prostatectomized patients in whom recurrence of a benign obstructing prostate occurred

ten and eighteen years respectively after operation. Only those cases should be classed as genuine recurrences in which, after perineal or suprapubic prostatectomy and after an interval of several years during which there is normal urination, the symptoms of prostatic obstruction reappear and a recurrent prostatic hypertrophy is definitely present by rectal examination and cystoscopic inspection or through the opened bladder, and in which there is not the slightest suspicion of malignancy. The hyperplastic growth probably starts in the submucous periurethral groups of prostatic glands situated in the region of the neck of the bladder. As these centrally placed glands of the prostate undergo hypertrophy and grow, they form an expanding adenomatous mass which presses on the outer layer of the prostatic glands, which gradually atrophy and become flattened and form the surgical capsule of the prostate. Ordinary enucleation of the prostate is merely the separation of one part of the prostate from another part of the prostate along an easy plane of cleavage. It is the shelling out of a tumor mass composed of the hyperplastic central glands of the prostate from the capsule, but the capsule may in the course of time take on new life, proliferate and occasionally undergo enough hyperplasia to form another obstructing growth, after the removal of the adenoma of the central glands which had been making pressure on them. After prostatectomy, very small nodules of hyperplastic tissue, often recognizable only under the microscope, can frequently be found in the surgical capsule. These hyperplastic nodules may continue their growth and eventually produce a recurrent obstructing mass.

Crampton Test and Surgical Shock—Irwin computed the Crampton value in 345 consecutive operative cases. There were fifteen deaths. Three of these patients were in shock. One of these had shown a zero record, the second a minus 80 record and the third had been too sick to record the Crampton value. The patients showing the two lowest Crampton values in the whole series died in shock. Of three others with low values of 15, 30 and 55, two died in four days with gangrene of the intestine and stone in the ileum and the other died a week after with carcinoma. All these patients were sick before operation and the vasotone was impaired, but not so much impaired as in those who were to die of shock. To sum up, the only recorded deaths of shock, when Crampton values were taken, showed very low values before operation. No patient with a high index before operation died of shock. The author's purpose was not only to see whether shock could be foreseen but also to see whether it could be forestalled and prevented. The methods employed were based on the fact that Crampton stated that digitalis, and sometimes squill, would bring up a low Crampton value. He stated that digitalis would first reduce the systolic pressure difference, next the pulse rate difference and lastly the diastolic difference, all depending on the capacity of the circulation to react. Accordingly, if possible, all patients were given the Crampton test. In all who showed a rating below 65, operation was delayed and digitalis was given until the test rose above 65. Two results were definite. Crampton's statement that digitalis would raise his index was verified. No case of shock resulted and not a patient was lost. Whether or not shock would have ensued without digitalis will not be known but the patients lived.

Pregnancy in Fibromyomatous Uterus—Studdiford reviews the relationship between pregnancy and the fibroid uterus. 1 Fibroids are a large factor in sterility. Certain selected patients may benefit from myomectomy, carrying subsequent pregnancies through to term. 2 Fibroids are a large factor in abortion and premature labor. Certain patients in whom such accidents have repeatedly occurred may be benefited by myomectomy and subsequently carry pregnancy through to term. 3 The chief dangers to patients having fibroids during the antepartum period is that of early interruption of the pregnancy and the onset of acute degenerative changes in the tumor. 4 The necessity for operative intervention because of degenerative changes in fibroids during pregnancy is rare. 5 Patients with small fibroids, if carried to term, often go through a normal labor. 6 Patients harboring large fibroids, usually elderly women are best treated by cesarean section and hysterectomy if carried to term. These patients are fortunate to have reached term and are not likely to carry another pregnancy this far. A living child is therefore more important than in the average woman. The risks of vaginal delivery are great. There is a possibility of acute degenerative changes beginning in the puerperium necessitating operation. They are likely to require surgical treatment for the fibroids within a few years. In a few instances cesarean section and myomectomy may prove practical. 7 Certain patients delivered by the vaginal route may develop acute degenerative changes in the puerperium requiring surgical intervention.

Irregular Genital Bleeding During Menopause—Keene made an analysis of the lesions responsible for bleeding in 2,000 women more than 40 years of age. He found that the lesions which produce bleeding from the genital tract prior to or during the menopause are benign in more than five sixths of the cases. After the menopause, nearly two thirds of the lesions are malignant. The benign lesions that produce premenopausal bleeding are located in the body of the uterus in two thirds of the cases and in the tubes and ovaries in one fourth. Benign cervical and vaginal lesions are comparatively infrequent causes of bleeding at this age. After the menopause, more than one half of the benign lesions are cervical and those of the vagina

rank second in order of frequency. The incidence of benign lesions in the body of the uterus drops to less than 17 per cent. Before the menopause, the malignant lesions of the genital tract are primarily cervical in more than three fourths of the patients. Although carcinoma of the fundus is essentially a disease of more advanced age, its incidence in the younger group is nearly 17 per cent of the total number of malignant lesions. Less than 10 per cent of these lesions are found in the adnexa, vagina or vulva. After the menopause the cervix is less frequently the site of cancer, but in this group more than one half of the malignant lesions developed here. The incidence of fundal cancer shows a marked increase after the menopause, rising to nearly 40 per cent. The remaining 7 per cent of the malignant lesions are equally divided between the cervix, the vagina and the adnexa. Prior to the menopause, benign lesions that cause bleeding are of a neoplastic or functional nature in more than 90 per cent of the patients; the neoplastic predominating. Irrespective of the type of lesion, ovarian dysfunction plays an important part. After the menopause, the majority of the benign lesions that produce bleeding are due directly or indirectly to the physiologic atrophy of the genital organs, incident to cessation of ovarian function. In this category fall the inflammatory and traumatic lesions of the vagina and cervix, and degeneration of uterine myomas. During and after the menopause, lesions of the cervix that cause bleeding are malignant in a high percentage of cases. Of the lesions in the body of the uterus that produce bleeding prior to the menopause, less than 4 per cent are malignant. After the menopause nearly 80 per cent of such lesions are malignant. Postmenopausal bleeding from the uterus may be of endocrine origin, but this is a rare occurrence. Such a diagnosis is warranted only after exhaustive examination has eliminated the presence of organic disease, particularly cancer.

Carcinoma of the Mouth.—Albright points out that more than 90 per cent of malignant tumors of the mouth are epidermoid carcinomas, mostly of the adult resistant type. Of the buccal epithelium, the basement cell alone has the power of reproduction and of invasion. All other cell changes represent stages of degeneration. Epulis, regarded by some as a granu-

loma, is "semimalignant." Leukoplakia is the most important precancerous lesion. All cases of leukoplakia are curable. Enlarged cervical nodes should be regarded as cancerous. Once cancer invades the cervical nodes, the chance for cure is practically lost. Early diagnosis will improve the results more than any other single factor. Radium is the treatment of choice of the primary lesion in all cases that have extended beyond the possibility of easy operative removal. Intratumoral radium must be of epidermicidal intensity, whether over a short or long period, to be reliably effective. In this form it is the best caustic for cancer. The 1934 technic of Radiumhemmet Stockholm, and Institut du radium, Paris, are presented. What cures there are in cancer of the tonsil have come from irradiation, which must be rigorously employed. In the treatment of the cervical lymphatic areas, irradiation is uncertain. It should be used only in combination with surgery which should be early and radical. The penalty of waiting until nodes develop is too great. Grading of tumors is of especial value in determining group prognosis. Better management of the individual case will result from the surgeon and radiologist working together.

Adenomyoma of Rectovaginal Septum—Bowling states that in radiotherapy of adenomyoma of the rectovaginal septum it is necessary to treat ectopic endometrial tissue, which has a histologic structure identical with that of the uterine mucosa. This tissue is influenced by the ovarian hormone. Infiltrating tumors in the wall of the posterior vaginal culdesac or in a corresponding region in the anterior rectal wall should not all be regarded as malignant. When the infiltration is atypical an effort should be made to obtain a satisfactory history, for in the average case the symptoms and signs will be influenced by the menstrual cycle. An effective method of treatment is a therapeutic menopause induced with radiation therapy; this is an indirect attack. In the management of young patients (before the age of 35) who are seen early, the neoplasm may be removed surgically or the patient may be observed for some time. Bimanual pelvic examination should be performed from every four to six months to determine any change in the neoplasm. This delay should not prove serious, as definite malignant degeneration was not proved in any of the cases studied. A trial treatment should be considered to determine possible beneficial effect of a temporary amenorrhea for at least six months to one year. The induction of a permanent therapeutic menopause with radiation should be considered. In the cases in which the lesion is advanced, there is no choice. The induction of a therapeutic menopause with radiation is recommended because it favorably influences this destructive neoplastic process. In the cases in which there is rather severe intestinal obstruction a colostomy may be considered, but it should not be performed until the pelvic infiltration has been reduced by indirect irradiation, because it is possible to overcome this serious complication. Mild catharsis, low enemas and a diet that contains little or no residue should be prescribed for a time following the radiation therapy.

Injection Treatment of Varicose Veins—Colt and his collaborators found that the injection treatment of varicose veins with salicylate (40 per cent)-saline (10 per cent) solution is safe and satisfactory in patients presenting a single varicosity, generally with a positive Trendelenburg sign, and a more extensive type of varicosity with a positive Trendelenburg sign and with a greater degree of deep reflux. Patients presenting a multiple spongework of small varicosities give poor results when treated in this manner. Although great amelioration takes place, a cure does not follow. It is as yet uncertain from the results published if more than amelioration can be obtained by operation, or by operation combined with injection, in this type of patient. In a small proportion of cases injection alone is not entirely successful, and ligation of the internal saphenous vein below its upper end is indicated as an adjuvant. No evidence sufficiently strong has yet been published to justify primary saphenous ligation in preference to primary injection with salicylate-saline solution. Almost all cases that have failed to react to other solutions can be successfully treated with salicylate-saline solution. The converse is not true, but sodium morrhuate appears to answer well in short lengths of vein when salicylate fails. Longer intervals than those commonly given between injections are evidently necessary if the accepted pathology of sclerosis is to be the guiding principle in treatment. Unna's paste bandage applied in the hydrostatic manner gives much better results than are obtained by the modern elastic-pressure applications.

Ligation of Veins with Arteries—Bell states that, in ligating the main artery to a limb the risk of gangrene is diminished by the simultaneous ligation of the corresponding vein. This is explained in terms of the equilibrium between the capillaries and the tissues. Ligation of an artery may cause the hydrostatic pressure in the capillaries to fall below the osmotic pressure of the plasma proteins. The circulation of

nutrient fluid to the tissues is thus impaired. Ligation of the vein will raise the capillary hydrostatic pressure and may thus restore the tissue circulation.

Leukocytic Invasion and Epithelial Metaplasia.—

According to Burrows, when an epithelium that does not normally form keratin is converted into a keratinizing epithelium an invasion by polymorphonuclear leukocytes is apt to occur. Leukocytic invasion may be observed in the vagina and uterus of the female mouse in the course of the natural estrous cycle, in the genital organs of the male mouse under continued treatment with estrogenic compounds, and in various structures in rats maintained on a diet deficient in vitamin A. Reasons are given for supposing that the leukocytic invasion in these conditions is a physiologic process and directly attributable neither to the presence of desquamated keratinous material nor to bacterial infection. The observations on which these conclusions are based were made by chance while the cellular changes induced by estrogenic substances were being investigated in an attempt to ascertain whether such changes might be associated in some way with the development of cancer. There was no opportunity to carry out a bacteriologic investigation of the kind required to establish fully the absence of bacterial infection.

Injection of Tuberculous Patients with Their Own Blood.—Amrein has the patient lie down, and 2 cc. of blood is removed from the arm vein by a sterile syringe. The blood is immediately injected into the gluteal muscles. The author treated by autohemotherapy fifty patients suffering from tuberculous infection of the elbow, tuberculous otitis, exudative pleurisy, pneumothorax effusions and pulmonary tuberculosis. The patients all responded well to treatment. They showed a

decrease in fever, an increase in appetite, a decrease in sputum and general improvement. The erythrocyte sedimentation test of the blood showed an improvement in a number of cases after one injection. In early cases this treatment creates an auto-immunization which helps the formation of encapsulation and calcification. Injections from every four to six weeks are useful.

Hemorrhagic Purpura Caused by Gold and Arsenical Compounds.—Hudson reports two cases of hemorrhagic thrombocytopenic purpura caused by administration of gold and arsenical compounds. Other recorded cases are reviewed but no definite reason for this complication is found. An idiosyncrasy or abnormal sensitivity of the patient is the probable cause. The eosinophilic response present in other complications of gold therapy is less obvious in the purpuric cases. In only two recorded cases was it above 4 per cent. No effective prophylactic measures are known, but a history of allergic or other abnormal responses should engender caution. Blood transfusion is the most effective means of treatment. Liver extracts may be given to aid blood regeneration. The leukocyte count is the most reliable guide to prognosis.

Cortical Carcinoma of Suprarenal.—Hare and her colleagues report a case clinically indistinguishable from the syndrome attributed to basophil adenoma of the pituitary. A carcinoma of the adrenal cortex was removed at operation and metastatic growth was found at necropsy. In serial sections of the pituitary no basophil adenoma was found. The differential cell count was within normal limits. A hyaline change that occurred in the basophil cells of the anterior lobe is described. This change should be considered an expression of altered physiologic activity and not a degeneration in the sense of a change leading to the death of the cell.

Virus Bodies in Pericardial Fluid of Rheumatic Fever.—Coles discusses his observations in examining microscopically pathologic material for virus bodies. He stresses his observations in a case of rheumatic fever, nine cases of rheumatoid arthritis and fifty cases in which death occurred in old age from various causes in which the pericardial fluid was examined. In the case of rheumatic fever small but very definite round or oval bodies, mostly isolated, a few in pairs, but rarely in chains, were observed in the Giemsa-stained films made directly from the pericardium. They were faintly stained red with Giemsa

and were best seen on the stained fibrin background. They resembled all other virus bodies not only in their difficulty in staining a faint red but also in the fact that they showed minute flagella like appendages which carefully examined under a high power. Of the fifty cases exactly half showed virus bodies closely allied to those found in the endocardium and pericardium of rheumatic fever. Of course, some other bacteria—e.g., diplo cocci streptococci—were also present. In five of the nine cases of rheumatoid arthritis, numerous virus bodies resembling those seen in the pericardial fluid of the patient with rheumatic fever were found. In all these cases films were stained also with Ziehl-Neelsen's method and a prolonged search was made for acid fast bacilli, however, in none of them did the author find any evidence of tubercle or other acid-fast bacilli. His impressions are that probably the virus bodies found in the pericardial fluid of the patient with rheumatic fever and those found in the joint fluids of rheumatoid arthritis may belong to the same species and might well represent the actual causal organism. From a clinical and pathologic aspect he believes that these two diseases are more closely associated with a virus than a bacterial origin.

Discharging Ears Treated by Iodine Powder Method. R. H. Bettington.—p. 747

Fracture of Neck of Femur—Hoets describes the curved cast and the Smith-Petersen nail as important aids to accurate reduction and adequate fixation of fracture. The curved cast enables a true lateral roentgenogram to be taken of the femoral neck. This is very difficult by any other method. The importance of this lateral view is that it has shown many a reduction which appears perfect in the ordinary anteroposterior picture to be imperfect. The Smith-Petersen nail is made of stainless steel. Its three flanges being only one thirty-second inch thick, it obtains a powerful grip on the fragments without displacing any appreciable bulk of cortex or spongy bone. A modification after King, by virtue of its central canal allows its placement over a Kirschner wire, the position of which is determined to be correct by roentgen examination in two planes. There are two ways of placing a Smith-Petersen nail with or without open operation. The use of the Smith-Petersen nail without open operation is the method of choice. Fractures through the neck of the femur without comminution are suitable for this operation. A fracture adjacent to the trochanter is suitable, provided the trochanter itself is sound. Both hips are included on the roentgenogram and a piece of metal notched at inch intervals, is placed on the skin of the lateral aspect of the thigh over the great trochanter. On the negative the length of the sound neck is measured against the metal strip and a nail of the correct length is prepared. The patient is anesthetized and placed on the traction apparatus. His feet are fixed to foot pieces. The fracture is reduced. Anteroposterior and lateral roentgenograms are taken to check the position. When the position is satisfactory, the prepared area is uncovered and a Kirschner wire is introduced. Roentgenograms are taken of the wire in position. The skin is swabbed with alcohol and a knife is passed down to bone along the wire. An incision of sufficient length is made and retracted. The starter is slipped over the wire, and the cortex is penetrated. The starter is withdrawn, and the nail is threaded on the wire and driven home. While the nail is being inserted it is necessary from time to time to use the impactor. The distal fragment tends to separate from the proximal as the nail enters the latter and must be driven back into position again. The wire is withdrawn and the wound is closed. After operation the patient is made comfortable with a soft pillow under the knee. This places the hip joint in a position of slight flexion and greatest comfort. The patient may sit up in bed as soon as the effects of the anesthetic have passed. There is slight soreness from the skin wound and some weakness in voluntary hip movements, but the limb may be moved passively without discomfort and without fear of any harm resulting. Massage and active movements to the limbs and unaffected joints may

be instituted at once, and gentle passive movements to the hip. For removal of the nail, local anesthesia is produced, a half-inch incision is made, and the nail is lifted out.

Foreign Protein in Treatment of Gonococcal Ophthalmia—Hamilton treated two patients presenting adult gonococcal ophthalmia with injections of cow's milk boiled for four minutes and given intramuscularly into the buttocks on alternate days. Commencing with 10 cc., he increased the dose rapidly to 25 cc. Of numerous foreign proteins and serums, milk produces the best uniform rise in body temperature. The one risk of milk injections seems to be anaphylaxis. At the first indication of distress, 10 minims (0.6 cc.) of epinephrine should be given hypodermically. Patients in whom milk injections are definitely contraindicated are those who are weak and debilitated, especially marasmatic children, tuberculous patients, persons with kidney disease and women in the last months of pregnancy. The author's patients responded well to treatment. They show that high pyrexia is a definite aid in the treatment of adult gonococcal ophthalmia. The pyrexia must be continuous and maintained until all discharge ceases. If the patient becomes immune to one foreign protein, another must be substituted. The use of a 2 per cent silver nitrate solution, however useful in other forms of ophthalmia, is strongly contraindicated in the treatment of gonorrheal ophthalmia even in the later stages. In all cases of gonorrheal ophthalmia with corneal ulceration, the whole cornea should be covered with a conjunctival flap at once. A purse-string suture carefully inserted is the only sure method of keeping the conjunctival flap in place for the desired period, namely, ten days or longer. The author concludes that massive doses of foreign protein, given intramuscularly or intravenously on alternate days so that the body temperature is left swinging at a high level are specific for gonococcal conjunctivitis in adults.

*Conditions Associated with Chronic Pulmonary Catarrh in Early Life. W. B. Wood.—p. 592

Treatment of Acute Otitis Media. F. H. Diggle.—p. 595

Hypnotic Drugs. G. S. Haynes.—p. 598

Id. F. B. Parsons.—p. 599

The Catarrhal Child—Wood describes the catarrhal child as one with a sallow complexion and dull eyes. Lymphatic hyperplasia is usually evident in the swelling of adenoid and tonsillar tissues, and malnutrition and underdevelopment are common. The ribs are prominent, owing to the thinness of the chest wall. Deficient expansion of the bases of the lungs causes a retraction of the chest below the level of the nipple. In generalized bronchial catarrh the signs of pulmonary catarrh may be accompanied by wheezing or may be associated with definite asthma. This liability to exudation suggests that some catarrhal manifestations may be due to allergic conditions. The exudative tendency is sometimes extreme and may even have tragic consequences. Nasopharyngeal infection is a usual concomitant of chronic basal catarrh, and contact infection often plays a part in its production. Between the more acute attacks of this disease, moisture lingers and crepitations are heard below the scapular angles. There is usually a history of bronchopneumonia in infancy. Since fibrosis is usually accompanied by bronchiectasis, the two conditions may conveniently be considered together. A massive fibrosis without bronchial dilatation is occasionally, however, a sequel of an interstitial pneumonia. In such cases the prognosis is apparently favorable. The saccular variety of bronchiectasis is relatively rare. Most of the entirely saccular bronchiectases may be due to congenital or developmental defects in early infancy, the arrest in post-uterine development of the lung having caused the persistence of large infantile alveoli to form the sacs. Symptoms may be

few or absent until secondary infection occurs, when acute purulent bronchiectasis may supervene on a dry condition. The cylindric type of bronchiectasis is common and is usually basal in situation. The theory that cylindric bronchiectasis may be the result of a vagal sympathetic imbalance has not yet been proved. Injections of iodized oil indicate that bronchial dilatation and bronchial spasm may occur in neighboring bronchi and that in the individual bronchus proximal dilatation may abruptly give place to distal spasm. Atelectasis involving a lower lobe is represented roentgenologically in the anteroposterior position by a triangular shadow, the apex of which corresponds with the proximal end of the main bronchus supplying the collapsed area. The inner margin of the triangle is obscured by the mediastinal opacity, the base blends with the diaphragmatic shadow and only the external margin is defined. The triangular shadow with its clear cut outer margin suggests a lobar delineation, but a lobular atelectasis may cause a similar appearance in the roentgenogram. Though atelectasis may be a temporary accident, in most cases the triangular opacity implies a permanent condition, the collapsed lobe containing dilated bronchi. Until clearer ideas are obtained on the etiology of the chronic pulmonary catarrhs and the prognosis in atelectasis and bronchiectasis, their treatment will remain unsatisfactory.

Surgery of Acute Empyema.—In operating for acute empyema, McGregor advocates resection of the eighth rib posteriorly or the sixth or seventh laterally. The time to discontinue drainage is when the cavity holds not more than 30 cc of fluid and when the pus has almost ceased to run. Heliotherapy, attention to diet and massage of the limbs may assist recovery. All empyema cavities should be irrigated with surgical solution of chlorinated soda, which assists expansion by thinning the thick resistant visceral pleura. The author refers to a method of closed suction drainage through a catheter introduced by trocar and cannula. The value of the method lies in the fact that drainage can be instituted in bed if necessary by a painless method, which does not put a further drain on the patient's resources and causes no shock. The patient is not disturbed after the catheter is inserted. There are no painful dressings and there is no risk of secondary infection. It is the only method that should be used in infants. The extended use of suction drainage in the treatment of empyema must not exclude rib resection from the therapeutics of this condition. Rib resection is a safe and valuable measure in adult patients in whom the mediastinum is firmly anchored. In infants, young children and those who are very ill rib resection should never be used. Here suction drainage finds its main application.

Treatment of Anal Fistulas.—Cabanie describes an operative technic for extrasphincter fistula which he considers superior to previous methods. After anesthesia the anus is dilated to three fourths of the maximum. The cutaneous orifice is encircled by an elongated incision, the axis of which is directed toward the anus. The external orifice thus freed is grasped with a hook. The fistula is dissected like a benign tumor. After excision, the rectum is sutured with catgut at rather close intervals. The anal mucosa is sutured but the cutaneous portion, properly speaking, is left free. The ischio-rectal fat, in which is exposed the external face of the sutured sphincter, must be allowed free drainage. This point is of major importance. An intra-anal drain surrounded by compresses extending into the ischio-rectal cavity completes the operation. The drain is removed on the fifth day.

Arterial Pulmonary Syndrome in Sinistocardia.—G  n  vier and Descomps discuss the syndrome of extravascular stenosis of the pulmonary artery, which is found with more or less accentuated displacement of the heart toward the left. The functional disorders that accompany this syndrome are inconstant and not characteristic. Inspection usually reveals generalized atrophy of the precordial musculature with visible arterial pulsation. Percussion allows easy determination of the border of the right side of the heart, while that of the left is difficult to outline. Palpation made with the tips of the fingers in the second or third interspaces reveals a systolic thrill and an accentuated diastolic impulse. A variable murmur is heard in auscultation, but it is constant in that it is of unquestionable vascular origin. It is usually systolic, more or less prolonged and sometimes infringing on diastole. The pathogenesis of the syndrome is disclosed by careful roentgenograms. They establish a perfect agreement between the appearance of the deformities and the clinical signs, which are not produced except when the displacement is accompanied by a deformation of the artery or its infundibulum. Three types of deformation are considered: deviation of the heart to the left, torsion of the heart around a vertical axis, and compression of the pedicle. It is interesting to note that the pulmonary artery syndrome thus produced is usually well tolerated. Decompensation when it occurs, is usually more dependent on the pulmonary parenchymal sclerosis and the obliterative arteritis than on the deformation of the arterial trunk. The prognosis therefore rests on the anatomic-pathologic condition of the lung.

Fecal Amylase and Its Behavior in Colitis.—Amalfitano studied the feces of twenty-four patients, of whom eighteen presented inflammatory intestinal disorders and six intestinal disorders concomitant with lesions of other organs. He determined the amylase content of the feces by means of the Wohlgemuth test. In patients having intestinal disorders without inflammation, the amylase content was normal. The amylase content was high in all cases of chronic intestinal inflammation and low in all acute intestinal inflammations. The deviation from normal was in relation to the state of inflammation of the intestinal mucosa. The author believes that the increase of

amylase in slight and chronic inflammations is due to a greater production of the ferment by the inflamed intestinal wall, to greater pancreatic production through the inflammatory stimulus, to lesser use of the ferment in the processes of digestion or to a combination of these causes. The diminution of the amylase content in cases of serious intestinal lesions is probably due to the decreased production of the ferment by a nondynamic, inactive and hypofunctioning organism.

Exophthalmic Goiter Treated with Milk of Thyroidectomized Goats—Pasquini Lopez found that the treatment of exophthalmic goiter by ingestion of varied amounts of the milk of thyroidectomized goats is superior in many cases to other medical treatments, even the ingestion of compound solution of iodine. All the author's cases responded well to this treatment. In grave cases the treatment ameliorates the patient's condition as much as surgical intervention and has none of the risks of operation. It has a favorable effect on the tachycardia, loss of weight and other secondary symptoms of the disease and produces prolonged improvement and sometimes complete disappearance of the symptoms. The author found no contraindications to the treatment.

Volkmann's Subluxation and Tuberculous Arthritis of Knee—According to Di Franco, Volkmann's subluxation is a type of tuberculous arthritis characterized by flexion contracture of the knee, external rotation of the leg, valgus position of the knee and frequently a bending of the upper third of the tibia. This type of tuberculous arthritis has been divided by Marconi into three roentgenologic groups corresponding to Volkmann's three types of flexion contracture of the knee: distention of the ligaments and alteration of the capsule, destruction of the femoral epiphysis and, finally, deformity of the femoral and tibial epiphysis. In all cases the flexion contracture is due to a local inflammatory process. In the frequently observed distention type, subluxation is due to alterations of the capsule and weakening of the ligaments, whereas in the deforming type it is due to defective development of the femoral epiphysis. The external rotation of the leg is due to the position of the knee in flexion of from 40 to 60 degrees, the weakening of the ligaments and sometimes the destruction of the bones. The valgus position is explained by the action of the biceps. The bending of the upper third of the tibia is due to the lack of resistance of the atrophied segment of the tibia to the contracture of the flexor muscles. The author refers to a patient treated by simple extension followed by immobilization of the pelvis and of the involved leg. The deformity recurred. He suggests as treatment for children aged from 3 to 5, upward and forward traction with the knee in flexion of 90 degrees for about twenty days to correct subluxation followed by extension to correct flexion. In cases complicated by rigidity of the joint or ankylosis of the knee in children aged from 8 to 10 he prefers arthrotomy and, in cases of great deformity of the knee with mobility of the joint, supracondylar osteotomy.

Action of Ultrashort Waves on Bacteria—Hasché and Leunig state that in previous reports they demonstrated that wavelengths of from 8 to 16 meters do not influence bacterial growth in vitro. In this paper they report their observations on the action of ultrashort waves of 35 meters and call attention to certain peculiarities of the short wave field. They stress the nonhomogeneity of the condenser field of short wave or ultrashort wave apparatus as one of the most important factors and show how it can be demonstrated. They investigated the effect of the 35 meter wave on staphylococci and Bacillus coli in distilled water or in bouillon and on water that contained micro-organisms. They found that the ultrashort waves do not inhibit the growth of these micro-organisms in vitro. Since it has been proved that the short waves or the ultrashort waves are effective in suppurative infectious processes, the aforementioned experiments prove again that the behavior of substances in the test tube is no indicator of their behavior in the human organism. However, the authors' chief aim was to find an object that would react to short waves and could then be used to investigate the action mechanism, the problem of dosage and the indications for the ultrashort waves. This object was not realized and the results seem to indicate that the action of the ultrashort waves in the human organism is produced secondarily.

Treatment of Meningitis by Roentgen Rays—Koehler followed the suggestion of Hippe and Likint and employed roentgen irradiation in the treatment of meningitis. In a patient with serous meningitis who six months previously had sustained a skull fracture, several irradiations with roentgen rays counteracted the severe headaches and the epileptiform convulsions. In another case of meningitis the bacteriologic examination demonstrated the presence of meningococci. The case was febrile and subacute, but severe involvement of the brain was absent. Small doses of roentgen rays were applied to the spinal cord, in fields of 6 by 8 or 10 by 12 cm. Six or seven fields were successively irradiated, from below upward. The focus distance from the skin was 30 cm and the filter consisted of 0.5 mm of copper and 15 mm of aluminum. The individual doses amounted to 20 per cent of the unit skin dose. The second irradiation of the lowest field had the most noticeable effect, for the fever ceased after it had been applied and it is assumed that the meningitic process was localized chiefly in the lower portion of the spinal column. The author maintains that the twenty-one lumbar punctures that were made in the course of the treatment had only a symptomatic effect and reduced the pressure, to be sure, the meningococcus serum sterilized the cerebrospinal fluid and an antipyretic preparation reduced the septic temperatures, however, reduction of the secretion of the meninges and complete cure were not effected until after the systematic roentgen irradiation.

Hereditary Diabetes Insipidus—De Lange reports the histories of two children with diabetes mellitus in whom, on investigating their history, she found that the diabetes insipidus had been passed on through four generations. Most cases were

mild. In the two children who were under clinical observation the diabetes insipidus was of the normochloremic-hyperchloruric type, the term hyperchloruria indicating that, although the sodium chloride concentration was low, it was not as low as in the other types. The author thinks it advisable to rehospitalize the two children from time to time to determine whether or not the further development of the disorder is along the same lines. In reviewing the literature, the author found that the manifestations as a rule do not develop until the children are several years old, that is, when the water exchange is transferred from the skin and the gastro-intestinal tract to the kidneys. However, a number of reports mention that great thirst was already observed during the nursing age. The symptoms are most severe between the ages of 20 and 30 years. After the age of 50 there is a lessening of the symptoms. Pregnancy seems to intensify them. Some reports mention mental deficiency in cases in which the disease is hereditary, and occasionally the green color of the urine is mentioned. The capacity of the bladder is increased in the majority of the cases. In the milder cases the concentration capacity, although reduced, is not entirely abolished. There are as yet no pathologic anatomic data on the hereditary form of diabetes insipidus. The patients may reach an advanced age. The disease seems to be more frequent in men than in women. The author thinks that the improvements supposedly obtained in some cases with iron and valerian preparations are the result of psychic effects.

Antagonistic Influence of Thyroid Hormone on Corpus Luteum and of Estrogenic Hormone on Pseudopregnant Uterus — With the thyroid hormone Engelhart produced pseudopregnancy in female rabbits by mating them with sterile males. In order to be positive that pseudopregnancy existed, an exploratory laparotomy was made and the ovaries were examined for the presence of ruptured follicles. Beginning with the second or third day of the pseudopregnancy, the animals were fed daily with thyroid substance. In the course of this treatment the typical symptoms of hyperthyroidism developed. The animals were killed after the pseudopregnancy had existed for eleven, twelve, thirteen, fourteen, fifteen or sixteen days and the ovaries and uterus were removed. It was found that the corpora lutea became atrophied under the influence of the artificially produced hyperthyroidism and that their influence on the uterus ceased, for beginning with the thirteenth day the uterus was again capable of reacting to solution of pituitary and the decidual mucosa of the uterus commenced to disappear. The author calls attention to the importance of the corpus luteum hormone for the undisturbed course of pregnancy, pointing out that the removal of the corpora lutea almost regularly produces abortion. He further studied the action of estrogenic substance on pseudopregnancy. The experiments he carried out in this connection proved that estrogenic substance does not, like thyroid, influence the corpora lutea as such (their appearance and function remain unaltered) but only inhibits the action of the corpus luteum hormone on the uterus.

Vitamin A Metabolism and Liver — Lasch mentions a number of investigators whose studies have seemed to establish definitely the dominating influence of the liver in the vitamin A metabolism. However, he considered it advisable to investigate this problem also in animals with impaired function of the liver. He reasoned that impairment of the liver could be produced by thyrotropic hormone or by phosphorus poisoning. Since other investigators had taken up the connection between

thyrotropic liver impairment and vitamin A metabolism, the author decided to give his attention chiefly to phosphorus poisoning. In experiments on rats and rabbits he found that fatal phosphorus poisoning does not influence the vitamin A content of the liver. He observed also that, if parenteral administration of vitamin A was combined with the phosphorus intoxication, the severely damaged liver of poisoned rabbits stored the same quantity of vitamin A as did the liver of normal animals. He thinks that this is due to the vitamin A metabolism effected by the reticulo-endothelial system, by Kupffer's stellate cells, which evidently are independent of the hepatic parenchyma and retain their storage capacity for vitamin A after the parenchymal cells have become greatly impaired.

Therapy of Insect Stings — Flury, in discussing treatment, points out that the mechanical removal of the venom by suction is impossible in the case of insect stings. Surgical procedures are rarely necessary, except in case of edema of the glottis. In the case of bee stings the removal of the sting is important. Another therapeutic measure is the neutralization of the toxin. This measure is based on the erroneous belief that formic acid is involved in the action of insect venom, but, in spite of this, the frequently employed ammonia is not entirely ineffective. Other substances that formerly were thought to be neutralizing agents, such as sodium bicarbonate, lime water, magnesium oxide and magnesia magma, are sometimes beneficial because they counteract the tension. Some measures are employed to make the venom insoluble. In this connection the author mentions one of the oldest remedies, namely, sodium chloride, which is dampened and applied or rubbed in. Other substances belonging to this group are magnesium sulphate, ammonium sulphate, some alcoholic preparations, tannic acid, plant juices that contain tannin and certain heavy metals. The author thinks that the use of heat likewise produces coagulation of the venom. He points out that frequently attempts are made to "burn out" insect stings. Tincture of iodine, compound solution of iodine, chlorine water, surgical solution of chlorinated soda and similar preparations aim at a chemical destruction of the venom. Potassium permanganate likewise is used much. To counteract the pain, local anesthetics may be employed and the itching may be counteracted by anti-inflammatory agents, such as the phenols and the volatile oils. As a prophylactic measure it is advisable to disinfect the wound with iodine, formaldehyde or a phenol preparation. The author thinks that most fatalities which occur in connection with insect stings are the result of bacterial infections rather than of the insect venom. The general treatment varies in the different cases. Stings into the blood vessels may produce severe symptoms that resemble anaphylactic shock. To counteract allergic conditions, epinephrine and intravenous calcium therapy have been recommended.

Diagnosis of Aneurysms of Hepatic Artery — Rimpler reports a clinical history in which the typical symptoms existed of aneurysm of the hepatic artery. There were recurrent attacks of pain in the right epigastric region, these pains were of the type that is indicative of a colic of the biliary tract and they were followed by melenas. The author points out that these symptoms might exist in a combination of gallstone colic with bleeding duodenal ulcer but that these two conditions could be excluded on the basis of the roentgenologic aspects. A second possibility was the existence of carcinoma of the duodenal papilla, but icterus was absent. The third disorder considered possible was an aneurysm of the hepatic artery. Since there were no indications of syphilis or a trauma, a mycotic aneurysm of the hepatic artery with perhaps a slow sepsis was thought of. The patient's general condition seemed to point in this direction. However, the further course did not

corroborate the existence of a slow sepsis. The fourth possibility considered by the author was the existence of a pulsating bleeding, colic producing metastasis of a hepatic carcinoma. In view of the progressive cachexia and of the change of the pulsating nodule into a hard nodule, carcinoma seemed likely and this was corroborated by the necropsy, which disclosed a scirrhous carcinoma of the caudal portion of the pancreas with metastases in the liver. The hepatic metastases had produced compression of the vessels and thus the pulsating nodule.

Iron Content of Malignant Tumors—Loewenthal and Probst think that the difference between the atomic weight of iron and that of the other tissue constituents is a decisive factor in ray therapy. They point out that hemoglobin, the iron bearing principle, has a high adsorption capacity for roentgen rays, and they think that this explains the sensitization of the skin by an excess of blood and the preservation of the skin in case it is anemic during roentgen irradiation. They further discuss the relationship between the hardness of the rays and the penetrating power of the secondary electrons and then report their studies on the iron content of tumors. They made studies on 176 malignant tumors from human subjects and on a number of carcinomas and sarcomas from rats. The iron content was determined by histochemical methods and in some cases also by chemical analytic procedure. Iron was found more often and in larger quantities in the primary tumors than in the metastases. This may explain the lesser ray sensitivity of the metastases. Comparative tests on irradiated and non irradiated tumors disclosed that the irradiated tumors have a higher average iron content. However, the author hesitates to draw definite conclusions from this. Irradiation seemed to produce no noticeable changes in the iron content of metastases.

Influence of Lead on Tumors—Von Pastinszky and Ottenstein introduced the so-called Ehrlich Putnoky rat blastoma strain into rats and then treated the animals with solutions of a colloidal compound of lead oxide and titanium trichloride. After large doses they observed a slight anemia and an exacerbation of the growth of the tumors, whereas the administration of small doses had no effect at all. The lead that had been injected into the tumors could be demonstrated in the subsequent histologic studies but only traces of the subcutaneously administered lead could be found. There were no indications of a specific tumor affinity for the lead even in the incinerated sections. In order to determine whether lead had a prophylactic action against tumors, it was administered to rabbits that were subjected to tar applications. The lead did not inhibit the development of the precancerous conditions elicited by tar. Since the lead preparations used by the authors contained also tannic acid, they decided to study the action of colloidal tannic acid and found that it slightly inhibits the growth of tumors. This inhibiting action could be further increased by the addition of colloidal copper to the tannic acid. Colloidal tellurium was tolerated in large quantities, but it did not cause the tumors to disappear and it produced a tendency to necrosis.

Potassium and Sodium in Sputum of Tuberculous Patients—In studies on the sodium chloride content of the sputum Zorn observed a number of elimination anomalies

particularly in patients with tuberculosis, which could not be explained entirely by a retention of chlorides. For this reason he determined the potassium and sodium content of 120 patients with various forms of tuberculosis and compared these values with the chloride values. The elimination in the urine was given consideration only in some of the patients. The author found that the elimination of sodium and potassium was not the same in all forms of tuberculosis. In the cirrhotic and productive cases there were no anomalies in the elimination. The patients with febrile tuberculosis, the exudative cases, the patients with early cavities and the cases in which the process had newly flared up always exhibited a noticeable increase in the potassium values and a reduction in the sodium values. These results indicate that the determination of the potassium and sodium values is helpful in deciding whether the tuberculous process is active or not. After having found that the potassium elimination is increased in exudative tuberculosis the author studied the effect of the salt-free diet on the potassium elimination and found that the diet inhibits potassium elimination. This indicates that the mineral economy of the organism is altered by such a diet. Further studies will be necessary to determine whether or not this change is beneficial to the organism.

Hydrocarbons in Stimulation Therapy of Tuberculosis—Kairiukstis uses mixtures of benzene-like aliphatic hydrocarbons to produce focal reactions. He shows that they are the manifestation of increased activity of the hematopoietic and the reticulo endothelial systems. In experiments on animals the repeated injection of aliphatic hydrocarbons resulted in a stimulation and increased functional activity of the two systems, for there were myeloid transformation of the bone marrow, hyperplasia of the spleen nodules, proliferation of the activated reticular cells and other changes in the internal organs. The author shows that the aliphatic hydrocarbons have an especially strong action on the reticulo-endothelial system. In the mixture of the aliphatic hydrocarbons used by him, heptane was the most important constituent and he says that this corroborated his assumption that among the aliphatic hydrocarbons heptane has the strongest therapeutic action. He concludes from this that the preparations consisting of mixtures of pure aliphatic hydrocarbons cannot be replaced by ordinary benzene solutions. The aim of the administration of hydrocarbons is to produce mild focal reactions, which can be done with doses of less than 0.1 cc. In a patient whose history is described in this report, the author gave every three weeks an intramuscular injection of 0.08 cc. of a preparation consisting of pure aliphatic hydrocarbons. After ten weeks, that is, after three injections, the large submaxillary nodules had practically disappeared at least as far as they could be seen from the outside. Only palpation revealed a few small nodules. The author warns against rapid increase in the doses in patients with tuberculosis. If the reactions become more severe at later injection, the doses should be slightly reduced. He expects that those who know the value of focal reactions in the treatment of tuberculosis and of other inflammatory processes will try the aliphatic hydrocarbons.

*So-Called Gas Peritonitis and Its Relation to Pneumatoxis Cystoides Intestinalis K Michejda—p 1695

*So-Called Intrafascicular Urethral Stenosis and Description of a Case O Reisch—p 1696

Venesection Following Operation for Exophthalmic Goiter—Lang reports a case in which a woman aged 25, with typical symptoms of exophthalmic goiter, submitted to an operation following preliminary Plummer treatment with iodine. The course of the operation was uneventful. Toward the evening of the day of the operation the patient became restless, the pulse increased, the respiration became more rapid and she had a livid appearance. Several hours later the signs of severe

postoperative intoxication were present. The patient was cyanotic and the respiration became slower and deeper. Her condition was grave. Since sedatives had been without effect, venesection was resorted to. After the withdrawal of 30 cc of blood from the bend of the elbow, improvement was noticeable. In all, 150 cc was withdrawn. The threatening symptoms disappeared and a restful sleep followed. The author thinks that several factors contribute to the efficacy of venesection. He thinks that the unburdening of the lesser circulation and the consequent improvement in the gas exchange within the pulmonary capillaries constitute the chief factor. It is possible also that the removal of toxic substances from the blood stream plays a part.

Gas Peritonitis—Michejda says that later observations in a case which he had reported as a spontaneous gas peritonitis make it appear probable that the gas peritonitis was not spontaneous but was the result of the escape of gas from a gastric ulcer. He calls attention to heretofore disregarded connections that exist between so-called gas peritonitis and pneumatosis cystoides intestinalis. He points out that the latter condition is found chiefly in patients with chronic gastric ulcer. He thinks that in this or similar conditions it is caused partly by the pressure of free gas into the open lymph clefts of the abdominal cavity and partly by the deficient resorption of the excessive gas, with subsequent encapsulation of the nonresorbed gas. Thus it appears that in some cases gas peritonitis may be a transitional form between ulcer perforation and pneumatosis cystoides intestinalis.

Infracollicular Urethral Stenosis—Raisch calls attention to a deformity in the urinary tract, namely, to valve formations in the region of the posterior urethra. These valves originate distad from the colliculus seminalis, take a forward course and are attached to the upper or lateral urethral wall. They are two pouch-like formations resembling somewhat the semilunar valves. They are open toward the bladder and thus obstruct the discharge of the urine and lead to a dilatation of the prostatic part of the urethra and gradually to an enlargement of the bladder and a dilatation of the ureters and of the renal pelvis. Catheterization becomes necessary and a secondary infection is likely. In case of unilateral valve formation the clinical symptoms may develop late, but if the deformity is bilateral the patient generally succumbs during the first years of life, unless there is a wide opening between the valves. In the diagnosis of this disorder the following factors play a part: 1. Since the valves open toward the bladder, a catheter can be introduced quite readily. 2. The spontaneous discharge of the urine is difficult. 3. In the advanced stage of urinary stasis, dribbling of urine is often observed. 4. If infection develops, the primary symptoms may be completely masked and the patient may die of septic or uremic symptoms. The author says that the prognosis is largely dependent on early diagnosis. It is important that the patient receive proper treatment before secondary infection develops. In nurslings and small children the valvular obstructions should be corrected by a transvesical intervention, while urethroscopic methods may be tried first in older children.

Plasma Transfusion in Hemolytic Shock—Heinatz and Sokolow show that recent research has given a better insight into the pathogenesis of hemolytic shock. It has been found that the arterial pressure decreases rapidly and that there is a continuous spasm of the vessels in the splanchnic region, chiefly in the kidneys. The ischemia of the kidney produces degenerative changes, which impair its secretory action (oliguria, anuria) and may cause a fatal outcome. Experimental

studies disclosed also that the vascular spasms of the splanchnic region are independent of the central and peripheral nervous system and are produced directly by the action of the hemolytic plasma on the vascular wall. Hesse and Filatow found that hemolytic shock can be successfully treated by the transfusion of large quantities of conserved blood, for this intervention counteracts the spasm and increases the blood pressure. Hesse's method proved effective in seven out of ten cases of hemolytic shock. The authors made experimental and clinical studies on the use of conserved plasma and found that it may be kept for three months and effectively employed in severe forms of operative shock and in cases in which considerable amounts of blood have been lost. After a discussion of the reasons why plasma therapy may be used instead of blood transfusion and of its advantages over blood transfusion, the authors describe a case that illustrates the beneficial effects of conserved plasma in the treatment of hemolytic shock. They think that plasma therapy is the method of choice in the treatment of acute hemolysis and stress that it involves fewer dangers and that it can be employed more quickly than blood transfusion, the latter factor being highly important in cases of this nature. They think that conserved plasma of the AB group, which may be used in all patients, should be kept on hand in all hospitals in which blood transfusions are made.

Old Fractures and Pseudarthroses of Neck of Femur—Böhler says that for years he has employed surgical methods in the treatment of the fractures of the neck of the femur. Since he became acquainted with the extra-articular nailing of Sven Johansson, he has used this method. He decided to employ it also in old fractures and in pseudarthroses of the neck of the femur. The extra-articular nailing is possible only if the fractured ends are in the correct position. Since, however, in most pseudarthroses of the neck of the femur displacements have taken place, these have to be overcome before the extra-articular nailing can be done. The author explains how this is accomplished and refers to a former report for an exact description of the operation. After the operation the leg is placed on a Braun splint and the foot is suspended on the crossbar. The drain is removed after twenty-four hours and the sutures after a week. After that, the patient commences with exercises on the knee-bending frame. When the patient sits up in bed, he makes movements in the hip joint. Knee, instep and toes are usually movable after two weeks. If complications are absent, a plaster-of-paris cast may be applied after two weeks. Whereas, in the case of new fractures of the neck of the femur the cast is left on for ten or twelve weeks in the case of pseudarthroses it has to be left on for six months or longer. In order that the ends of the fractures may be pressed together again and again, the patient is urged to walk and to stand on the injured leg. In this manner osseous healing is produced even in old fractures and in pseudarthroses. The author reaches the conclusion that, because of its simplicity and its reliability, extra-articular nailing is superior to all former methods, to subtrochanteric osteotomy, to riveting with a bone splint and to implantation of the neck of the femur into the acetabulum.

SECONDARY TUMORS OF THE URETER

A CONSIDERATION OF THE VARIOUS TYPES,
WITH A REPORT OF TWO CASES

CHAIRMAN'S ADDRESS

STANLEY R WOODRUFF, M.D.
JERSEY CITY, N J

In the twelve years since the publication of a case report by Giordano and Bumpus¹ progressively increasing interest has been shown in secondary tumors of the ureters. The rarity of true metastasis to the ureter from adjacent pelvic organs, so often the seat of malignant disease, is difficult to explain when one remembers the frequency of occurrence of carcinoma of the bladder and the fact that the lymphatic vessels of the two organs communicate, unless one agrees with Robinson² that the lymphatic drainage of the lower portion of the ureters is downward. This is also true of other pelvic organs in both the male and the female. Even as rare a condition as primary carcinoma of the ureter appears to be, I am inclined to believe with Glas³ that true metastases are even rarer, and it appears that the histologic structure of the ureter is somewhat immune to malignant invasion. Surely one must be impressed by the fact that a large number of the cases of true metastasis reported come from such rather remote organs as the breast stomach and lung. My observations would force me to believe also that there are many metastases to the ureter that are entirely missed because of their small size and the lack of symptoms. The most frequent metastatic growths of the ureter are really inoculation or implantation metastases from an original papillary carcinoma of the renal pelvis.

CLASSIFICATION

In order to clarify these conditions I have endeavored to formulate a classification of secondary tumors of the ureter based on pathogenic principles.

- I. Involvement of the ureters by the urogenic route
 - (a) In the direction of the urinary flow (from the kidney or pelvis)
 - (b) Retrograde (from the bladder)
- II. Involvement of the ureter by direct extension from a neighboring viscus
 - (a) Encircling the ureter without infiltration of the ureteral wall

(b) With infiltration of the ureter

- 1 Without encroachment on the lumen
- 2 With encroachment on the lumen
- 3 With subsequent rupture into the ureteral lumen
 - (a) Further dissemination by the urogenic route (as in group I)
- 4 With subsequent invasion of the blood or lymph channels (acting as a supplementary focus for further dissemination)

III. Involvement of the ureter by the blood or lymph channels (genuine metastases)

IV. Combination form (combination of any of the former)

V. Involvement of the ureter by lesions that may be of multicentric origin

(a) Diseases of the hematopoietic system

- 1 Hodgkin's disease
- 2 Lymphosarcoma
- 3 Leukemia
- 4 Reticulosis

GROUP I. Involvement of the Ureter by the Urogenic Route—(a) Clinicians are fully cognizant of the tumors that arise in the renal pelvis and metastasize down the ureter by way of the urinary stream. Such implantation may continue onward into the bladder, where papillary tumors grow with great facility. This condition has been demonstrated to be so common that urologists now feel it necessary to make a thorough study of the ureter and renal pelvis by the usual methods in every patient showing papillary growths in the bladder. Albarran⁴ first brought attention to the ease with which papillary tumors of the renal pelvis can become implanted in the mucosa of the bladder. Hunt⁵ in 1927 reported fifteen cases of papillary epithelioma of the renal pelvis, which series was later covered by Kimball and Ferris⁶ in their recent (1934) review of the literature in connection with such tumors. They collected reports of seventy-four cases, in fifty of which metastases appeared in the ureter and bladder. In only one of these cases does it appear that the ureter alone was the subject of metastatic implantation, but in twenty-four cases or 48 per cent, the ureteral orifices were involved while in eighteen cases, or 36 per cent, both the ureteral orifice and the bladder showed papillary tumors. Cabot and Allen⁷ in 1933 reported forty-five cases nineteen of which were also included in the data of Kimball and Ferris. In the remaining twenty-six cases there were seven metastatic implantations in the ureter. The accepted procedure in operating on a patient suffering from papillary carcinoma of the renal pelvis now includes total extirpation of the ureter along with a portion of the vesical wall, even in those patients

in whom no secondary growth of the ureter or bladder can be demonstrated. Metastasis of the ureter from the renal pelvis appears to take place by the actual adherence of tumor cells to the mucosa, with subsequent implantation on it as they float down in the stream of urine, and not by lymphatic or adjacent growth

Fig 1—Pyelogram with the catheters in place

(b) Retrograde dissemination of neoplasms upward was mentioned by Ewing.⁸ He described several papillary tumors of the bladder which extended into the lumen of the ureter. Boeger's⁹ patient died two years after resection of the sigmoid flexure for carcinoma. At necropsy a tumor was found in the left ureter, with dilatation of the ureter and pelvis above it. There was carcinomatous involvement of the medulla of the kidney and pelvis. In this case the author believed that the patient had metastases at the bifurcation of the aorta at the time of operation, and that these tumors grew into the adjacent tissues, invaded the ureter, broke into the lumen and then gave rise to renal and pelvic implants by the retrograde urogenic route. The ureter above and below the constriction was found to be uninvolved in the tumor process.

GROUP II Involvement of the Ureter by Direct Extension from a Neighboring Viscus—(a) That the ureters may be embedded in adjacent extra-ureteral tumors without actual invasion by them was shown in Martin's¹⁰ case of primary carcinoma of the cervix with metastasis to the vagina. The ureter in this instance was completely encircled by tumor tissue for a distance of 2 cm. In spite of this the ureter could be easily freed from the tumor, the latter being removed at operation. The ureteral wall was found to be free of invading tumor tissue.

The literature is full of reports in which pressure on the ureter by an adjacent tumor has been the cause

of marked changes in the ureter, the result of stricture of the ureter usually being ureterectasis and pyelectasis, which is commonly followed by infection resulting in pyonephrosis and destruction of the kidney. Herger and Schreiner¹¹ reported twenty-one such cases in a series of autopsies on thirty-two patients who died of carcinoma of the cervix.

(b) 1 More aggressive tumors adjacent to the ureter may, however, infiltrate its wall with or without interference with the lumen. In Maruyama's¹² first case the lumen was not obliterated even though the wall was infiltrated.

2 In Myers' ¹³ patient anuria developed thirty days before death about four months after hysterectomy for carcinoma of the cervix. At necropsy both ureters were found to be incarcerated in a pelvic mass which had already infiltrated the ureteral walls and occluded the lumens.

3 After the tumor has invaded the ureteral wall, it may rupture into the lumen and then spread by the urogenic route to other portions of the ureter, to the bladder or retrograde to the pelvis and kidney (as in Boeger's case described in group I).

4 After the tumor has invaded the ureteral wall, this secondary tumor may act as a supplementary depot for further dissemination by way of the lymph or the blood stream. In Maruyama's ¹² first case there was a large mass in the pelvis extending from a carcinoma of the cervix. The left ureter was invaded and embedded in this mass, but its lumen was not obliterated. The lymphatic vessels extending up to the ureter were infiltrated by tumor tissue. In this instance it is difficult to decide whether the lymphatic extension was from the pelvic mass or from the involved ureter. The second source, however, is more likely.

Fig 2—Uterus, cervix and vagina showing an ulcerated lesion of the cervix extending into the vagina and encroaching on the cervix.

GROUP III Involvement of the Ureter by the Blood or Lymph Channels (Genuine Metastases)—The first to stress invasion of the blood stream by tumor cells

were Giordano and Bumpus in 1922¹. They reported a case in which there was a carcinoma of the prostate with metastasis to the left ureter. In 1924 Thomas and Regnier¹⁴ reported a case of carcinoma of the bladder with metastases to the right ureter. They made no mention of perivascular lymphatic vessels, merely stat-

Fig 3—Section under low power showing ulcerated lesion with invasion of deeper tissues by nests of tumor cells

ing that the cervical, inguinal and mesenteric lymph nodes were involved. Carson¹⁵ in 1925 stressed invasion of the lymphatic vessels reporting three cases, one from the bladder, another from the prostate and a third from the cervix. In 1927 Carson¹⁶ described two additional cases that fall into this group, both from the prostate.

Rathbun¹⁷ in 1929 reported a case in a male occurring three years after mastectomy for carcinoma. Urinary symptoms developed at that time and a urologic examination established the diagnosis of renal tumor, probably carcinoma. Excision of the left kidney and partial ureterectomy were performed and a tumor nodule, having the characteristics of the original breast tumor, was found in the wall of the ureter. The author made no mention of lymphatic extension, but that was undoubtedly a case of true metastasis.

Kirshbaum¹⁸ reported five cases of involvement of the ureters, the first subsequent to mastectomy for carcinoma, the third secondary to bronchial carcinoma and the fourth and fifth originating in prostatic carcinomas. His second case was one of Hodgkin's disease, which will be included in a special group.

In considering the cases of true metastasis to the ureter, one must not be overcautious and include only those instances in which tumor is present within the lymph or blood channels. In the first place it is not uncommon to find a lymph node involved in a tumor process without demonstration of neoplastic tissue within the afferent or efferent channels. Indeed, one

would be compelled to make serial sections, and even then the cells would not necessarily be demonstrated. This is particularly so in those cases of infrequent sporadic invasion in which the cells are immediately propelled through the lymph vessels without involving either intermediate lymphatic gland or the very channel through which it traveled to its new nidus. Furthermore, in those cases in which the lymphatic vessels are found to be actually involved it might well be an efferent vessel as in Maruyama's first case, since one cannot differentiate an afferent from an efferent lymphatic channel. Again, supposing these could be differentiated, the possibility of retrograde involvement must necessarily be considered.

Therefore, all cases in which the ureteral involvement is not in direct continuity with the primary or adjacent tumor, even though actual invasion cannot be demonstrated, should be considered as possibly falling into this group.

In Grenel's¹⁹ case of carcinoma of the lesser curvature, both ureters were dilated at the pelvic brim, where they were found to be infiltrated by carcinomatous tissue. The corresponding nodes at the points of obstruction were found to be involved in the tumor process, but they did not compress the ureter in those areas. This case evidently falls into the group of cases emphasized in this paper, even though the tumor cells were not found within the lumen of the lymphatic channels, otherwise one could not explain the migration of neoplasm from the ureter to the corresponding lymph node, or vice versa.

There are numerous other cases which in all likelihood border on or belong in this group, although no direct mention of this is made in the presentation.

Fig 4—Kidneys, ureters and bladder. The ureters are thickened and infiltrated.

Zinner²⁰ reported a case in which hysterectomy was performed for columnar cell carcinoma of the uterus two and one-half years before the patient's death. At necropsy, tumor nodules were found in the right ureter 5 cm below the ureteropelvic junction and in

the left ureter 4 cm above the orifice. Those nodules were apparently metastatic and not in connection with the remnants of primary tumor tissue.

Bauer²¹ in discussing this case mentioned one of his own cases, that of a man, aged 50, with carcinoma of the stomach and metastasis to the left ureter.

Case 3 in Glas's³ series is a more complete report of Bauer's case. Glas's second case was one of carcinoma of the prostate in a man, aged 74, with involvement of the lymph nodes and lower third of both ureters. An isolated node in the left ureter, together with involvement of the regional lymph nodes, was found. In his fourth case, a woman, aged 50, had one breast amputated for carcinoma fifteen years before death and an ovarian carcinoma removed two years before death. At necropsy, metastatic carcinoma of the

Fig. 5.—Section of the ureteral wall under low power showing intact but inflamed mucosa and the infiltration of the muscular coat and perimuscular areas by tumor tissue. Note the increase in connective tissue about the neoplastic areas.

inguinal and retroperitoneal lymph nodes with infiltration of both ureters was found.

Eisner²² reported the case of a 45 year old man with pulmonary tuberculosis, pernicious anemia and carcinoma of the stomach. In the perirenal tissues there were tumor masses which encroached on the ureters. He mentioned the possibility of lymphatic spread but did not specifically state that his case belonged to that group. His second case of carcinoma of the stomach, in which there were metastases to the peritoneum, ovaries, bladder and right ureter, may also fall into this group.

MacKenzie and Ratner²³ reported three cases of true metastases to the ureter. In two cases autopsy was

performed. In one case a diagnosis was made prior to operation and represents practically the only case under this heading in which a preoperative diagnosis has been made. In the first case there was metastasis to the right ureter and ileum from an adenocarcinoma of the stomach. It had caused pyonephrosis of the right kidney. The second case was one of adenocarcinoma of the prostate with metastases to the ureters, lungs and pleurae. The finding of cancer cells in the perivascular lymph spaces definitely proved the true metastatic nature of the growth. Pyonephrosis of the right kidney also was present. The third patient was suffering from carcinoma of the cervix and had been given radium treatment. Examination about a year afterward failed to reveal any recurrence of the growth. However, on admission to the hospital at that time she complained of frequency of urination and pain in the left iliac region, anorexia and loss of weight. This condition had been present for about four months. Urologic examination led to a diagnosis of ureteral obstruction and an infected pyelectasis of the left kidney. Excision of the left kidney and partial ureterectomy were performed. A congenital anomalous kidney was found with a double pelvis and two ureters which anastomosed in the upper third. At their junction was a hard mass the size of a large grape. It was removed along with the kidney and upper portion of the ureters. Pathologic examination showed this mass to be a metastatic carcinoma from the cervix.

GROUP IV. Combination Forms.—It is obvious that any combination of the aforementioned types of metastases may exist, and it is not necessary to give any details of cases.

GROUP V. Involvement of the Ureter by Lesions Which May Be of Multicentric Origin.—(a) It is not infrequent to find ureteral involvement in cases of tumor of the hematopoietic system. These tumors may arise in situ from the resting mesenchyme or from reticular cells.

Kirshbaum's¹⁸ instance of Hodgkin's disease falls into this group. Bond Stow's²⁴ case of fibrolymphosarcoma of both ureters, which he considered secondary to lymphosarcoma of the anterior mediastinum, is most likely one of this variety. He reported that all the lymph nodes were involved. This was in all likelihood a case of lymphosarcoma.

A 14 year old girl with subleukemic myelosarcoma involving the heart, stomach, appendix, ovaries, tubes, ureters, kidneys, bladder, liver and all the lymph nodes with nodes in both ureters which gave rise to obstruction with dilatation of the ureter and pelvis, was admitted to the hospital, because of nodules in the skin and asthenia with progressive anemia. Under observation, new nodules occurred in the skin and in the breasts. The liver became enlarged, as did also the spleen. The patient finally died. Within the ureters were seen numerous nodular infiltrations, varying from 2 to 8 mm in diameter, which in places completely occluded the lumen of the ureter. The pelvis and terminal calices were dilated, and infiltrations were seen between the pelvis proper and the medullary portion of the kidney.

Even though no case has been reported in which reticulosis of the ureters was present, this is a likely possibility and is added for the sake of completeness of the classification.

SYMPTOMATOLOGY

It is apparent to the urologist that the symptoms resulting from secondary tumors of the ureter vary according to the amount and type of the invasion. No doubt there are many instances in which no symptoms develop, and it stands to reason that many cases probably remain unnoticed. If there is little or no pressure on the ureteral lumen only slight symptomatology will result, but with the advent of obstruction and probable later infection the complaint will follow the usual course of such conditions. The extent and type of renal involvement will determine the symptoms as they will in all probability relate to the pathologic condition of the kidneys, and the presence of ureteral complication will be difficult to determine. Pain in the back as an early symptom was noted in almost all the cases that have been reported and was present in my own case. Sudden and complete anuria, as occurred in my patient, is extremely rare, but was noted by Schlagintweit.²⁵ He described a case in which this symptom developed and at autopsy bilateral metastatic carcinosis of both ureters from primary carcinoma of the stomach was discovered. Usually the patient shows only the symptoms relative to ureteral obstruction, such as pyelectasis with or without infection.

The case to be presented here belongs in the third group—cases of true metastases. This case is interesting not only from the standpoint of the rare pathologic observations, but also because of the peculiar symptoms, which made diagnosis impossible and thereby caused the treatment to be mostly expectant.

REPORT OF CASE

History—H. C., a white woman, aged 42 on admission to the hospital complained that no urine had been passed for six days. During that time there were two attacks of chills accompanied by fever. She also complained of nausea and vomiting and some lumbosacral backache. Her present illness began about one month previous to admission. While reaching for a telephone she was suddenly seized with a pain in the lower portion of the spine. At first severe it gradually subsided until a rather dull constant ache remained. She received medical attention at that time and was treated by several physicians for lumbago. During that time there were no genito-urinary symptoms. There was no history of any recent infectious disease.

Physical Examination—The temperature was 102 F, the pulse rate 116 and the respiratory rate, 20. The patient appeared to be seriously ill and toxic. Nothing of particular interest was elicited by physical examination except the following. The abdomen was slightly distended but was soft and showed no masses or areas of tenderness. Pelvic examination revealed an ulcerated area in the vagina which was palpated by the finger. In view of the fact that it was not particularly indurated and showed no connection with any underlying organ it was considered to be of no great significance as far as the chief complaint was concerned. The regions of the kidneys showed no particular tenderness or rigidity. The reflexes were not abnormal. There was no edema. The blood pressure was 204 systolic and 120 diastolic.

Laboratory Examinations—Chemical examination of the blood revealed 100 mg of urea nitrogen per hundred cubic centimeters and 8 mg of creatinine. The blood count showed 16,200 leukocytes with 84 per cent polymorphonuclears. The hemoglobin content was 60 per cent.

When the patient entered the hospital catheterization was attempted but no urine was found in the bladder. Roentgen examination of the genito-urinary tract revealed that both kidneys were normal in shape, size, position and density. No evidence of calculous disease could be demonstrated at any point in the urinary tract. Cystoscopic examination showed that there was no urine in the bladder and that all the mucosa

had a normal appearance. A catheter was passed to the pelvis of the right kidney without difficulty and 150 cc. of urine was obtained in a short time. An unsuccessful attempt was made to pass a number 5 catheter up the left ureter, but as the patient's condition became somewhat alarming it was decided not to make a further attempt. The urine from the right kidney contained a few white blood cells, many red blood cells, no casts and 1+ albumin.

Course—During the next twenty-four hours the patient had several chills, the temperature rising to 103 F along with a pulse rate ranging from 120 to 140. The output from the catheter in the pelvis of the right kidney was 2,700 cc. This catheter became blocked during the afternoon and could not be freed. After removal of the catheter, no urine passed into the bladder. Cystoscopy was again performed and the right kidney was catheterized, 150 cc of slightly cloudy urine being obtained from the pelvis. The pelvis of the left kidney was successfully catheterized on this occasion and 75 cc. of clear urine obtained.

Bilateral delineation of the renal pelvis with the aid of a contrast medium was carried out, the result showing that the

Fig. 6—Section under higher power showing tumor cells between muscle bundles and connective tissue fibers as well as within endothelium lined channels.

pelvis of the left kidney was normal, while that of the right kidney was a trifle dilated. Unfortunately, the catheters were not removed from the pelvis when the pyelogram was made, so that delineation of the ureters was not accomplished (the cystoscopist was loath to remove the catheters after having successfully placed them in the renal pelvises). The urine obtained from the two kidneys was practically identical.

The patient had a bad night and complained of nausea and headache. Again the temperature was elevated and the pulse rate was accelerated. On the third day the output from the right kidney by catheter was 1,220 cc. and that from the left, over 540 cc. On that day the catheters again ceased functioning and were removed, fresh catheters being inserted in the afternoon. The urinary output continued as usual.

On the fourth day the blood pressure dropped to 128 systolic and 82 diastolic. The pulse rate was 130, the respiratory rate was 20 and the temperature averaged 102 F. No estimation of the amount of urine passed through the catheters was possible on account of the frequent irrigation, the amount of which was not checked. There seemed to be slight improvement in the patient's condition.

²⁵ Schlagintweit cited by Glas.

On the fifth day the urinary output for the twenty-four hours was 1,600 cc. Chemical examination of the blood revealed 50 mg of urea nitrogen, 1.58 mg of creatinine and a carbon dioxide combining power of 48. Indigo carmine given intravenously appeared on the left side in four minutes, showing a 2+ concentration. On the right side it appeared in twenty minutes with a 1+ concentration. The patient continued to improve from the standpoint of chemical blood analyses, and the total urinary output averaged from 1,400 to 2,000 cc in twenty-four hours, as long as the catheters remained in place.

Indigo carmine was injected intravenously on the sixth day and appeared in ten minutes with a 2+ concentration from each kidney. Urinary cultures showed *B. coli* from each kidney and a nonhemolytic streptococcus from the right kidney. Any attempt to remove the catheters was followed by total failure to pass urine into the bladder, a sharp rise in temperature, severe chills and a general breaking down of the patient's morale.

Despite the patient's poor condition it was decided to institute nephrostomy drainage of the right kidney. This was successfully accomplished on the ninth day without any apparent shock to the patient. At operation the upper portion of the ureter was noted to be much thickened, indurated and inelastic but

Fig 7—Low power view of perireteral tissues showing nests of tumor cells within the perivascular lymphatic channels. Note the occluded blood vessels with neoplastic tissue within its wall.

did not give the appearance of a malignant condition. The drainage from the nephrostomy was, however, somewhat disappointing, the amount being much less than had been obtained by catheter drainage. The course for the next three days was satisfactory, the temperature remaining around 100 F and no chills intervening.

On the fourteenth day the twenty-four hour output was 900 cc from the nephrostomy tube and 650 cc from the catheter in the left kidney. The blood chemistry values, however, began to rise, showing 81 mg of urea nitrogen, 3.52 mg of creatinine and a carbon dioxide combining power of 44. Indigo carmine again appeared from each side in ten minutes and showed a 1+ concentration.

The patient's condition became progressively worse although the urinary output was within fair limits, owing probably to the large amount of medication given intravenously, subcutaneously and through a duodenal tube. The plan to perform nephrostomy of the left kidney was abandoned because of the patient's poor condition. On the eighteenth day after admission the patient died.

Postmortem Examination—In the anterior portion of the vagina, in the region of the fornix, there was found an area of ulceration which almost completely encircled the cervix. It extended externally on the left side for a distance of about 1 cm and internally on the external os of the cervix. The uterus showed no significant changes on gross examination.

The ovaries were slightly enlarged. In them were seen a few grayish nodules, especially near the ligamentous attachment. The tubes were slightly thickened, but their lumens could be probed. On cut section the thickening was found to be due to grayish cellular tissue, subperitoneally located, which did not communicate with the lumen.

The urethra and trigon were injected.

There was a nephrostomy opening in the right kidney and evidences of a purulent perirenal inflammatory reaction extending to the upper portion of the ureter. The capsule of the right kidney could not be stripped. The cut surface of the kidneys had a grayish appearance, and scattered throughout, most pronounced in the lower portion, were numerous grayish necrotic areas ranging in size from that of a pinpoint to that of a pin head. The lower half of the pelvis of the left kidney was necrotic and gangrenous. The remainder of the pelvis was thickened and had a granular surface. The right kidney also was slightly enlarged but the small, necrotic areas were not as numerous as in the left kidney. The pelvis of the right kidney was markedly hemorrhagic.

The two ureters showed essentially the same changes. The walls of the upper portion of the ureters were thickened. At one point in the right ureter, about 2 cm below the ureteropelvic junction, the wall was firm, inelastic, sclerosed and intimately adherent and fixed to the perireteral tissue. However with moderate difficulty the lumen could be probed. The lower two thirds of the ureters also were slightly thickened and inelastic; the last 2 cm showed no obvious gross change. The left ureter in its second upper centimeter was denuded of epithelium and instead there was an ulceration with necrotic tissue in the base. This was just above the point at which the ureter was fixed to the perireteral tissues. The ureters were not in direct contact with any of the tumor masses in the other organs. Both ovarian veins were surrounded by a type of tissue similar to that surrounding the upper portion of the ureters. This was most marked about the left ovarian vein, in which there was a thrombus extending for a distance of about 10 cm up to its opening into the renal vein.

Microscopic examination of the tissue in the fornix showed an ulcer in the base of which there were epidermoid cells infiltrating in the form of pegs into the deeper layers. There was moderate atypism and irregularity with not infrequent mitotic figures. Immediately beneath this the tumor cells were found to be within the perivascular lymphatic vessels. The deepest tissues of the cervix and vagina showed a minimal involvement by tumor tissue.

Both kidneys showed evidences of pyelonephritis.

The conditions of the two ureters were similar. There was a pronounced invasion of the outer layers of the muscularis and perimuscular region by tumor cells. Mitotic figures were frequent. There was a prominent scirrhous reaction about the nests of tumor tissue. These neoplastic cells were found to be present not only between the individual muscle fibers but also in the perivascular lymphatic channels in the perireteral tissue.

The nodules in the tube and ovary were found to be made up of tumor cells. Sections taken through the ovarian veins showed tumor tissue in the perivascular and perineural lymphatic vessels as well as within the walls of the veins. These cells extended to the intima. Some of the smaller radicles were completely occluded by an organizing thrombus, in the meshes of which some tumor cells were found. The thrombus in the ovarian vein was found to be in apposition with that portion of the wall which was invaded by tumor tissue.

A lymph node removed from the region in which the involvement of the ureter, as well as of the ovarian vessel, was most pronounced, showed no invasion by tumor tissue.

COMMENT

As to the mechanism causing obstruction by tumor nodules within the ureter proper, one must consider various possibilities. Most frequently obstruction is due to an expansive growth of the nodules with encroachment on the lumen. I shall mention only those cases in which the tumor arises in adjacent tissue and

compresses the ureter from without. There are also cases in which a sclerosing reaction to the tumor cells results in stricturing with obstruction. These, however, do not explain the case herewith described. On the left side the ureteral lumen was obstructed and the catheter was passed with difficulty. The predominant factor was the marked fibrosis in the ureteral wall with contracture of the connective tissue, thereby occluding and markedly narrowing the lumen. On the right side however the ureter was patent and yet no urine passed except through an indwelling catheter. The scirrhous infiltration of the wall with some narrowing of the lumen was an appreciable factor but could not entirely explain the failure of passage of urine, nor could the additional factors of lack of peristalsis and nervous involvement completely account for it. The possibility that edema had disappeared before necropsy is plausible and likely. One must however, consider also invagination of the upper ureteral segment into the thickened and scirrhous portion, which is extensively and firmly fixed to the periureteral tissue. A wave of contraction in the superior portion which is not so markedly infiltrated, reaches this fixed position and not being able to pass along, invaginates the upper segment into the sclerosed fixed lower area. Telescoping with resultant intussusception, which is so frequently found in the intestine, cannot take place because of the rigidity of the lower tube and its lack of expansile power. However, the mere dimpling-in of the upper into the lower segment may be sufficient to act as an obstruction to the passage of urine.

ABSTRACT OF DISCUSSION

DR. H. S. JECK, New York. Dr. Woodruff's classification of metastatic tumors is admirable in its simplicity. His interesting case of bilateral metastatic carcinoma falls in the group of true metastases. I agree that one should not be too meticulous in including in this true metastatic group only those tumors that show cancer cells in the lymph channels and the blood stream. At autopsy many of these tumors are doubtless true metastases but it is difficult to prove it. However, the pathologist who performs the autopsy is often convinced of the true metastatic character by the relationship of the gross conditions observed. With reference to the implantation of tumor cells in the ureter from papillary carcinoma of the kidney, it is doubtful that this ever occurs. It would imply a pathologic condition of the ureter of some sort, such as an obstructed ureter or an inflamed ureteral mucosa or a combination of the two. I recently operated on a patient who comes under Dr. Woodruff's group classification II. The upper end of the ureter was considerably dilated, there was an obstruction about 12 cm. down from the ureteropelvic junction and as far down as one could reach one could feel friable, firm tissue surrounding the ureter. Some of this tissue was removed and proved to be carcinomatous. I have a case which I believe belongs to the third group. The pathologist was of the opinion that it was a case of true metastasis. The history obtained in this man of 60 indicated that six months prior to his admission he had had sharp intermittent pains in the left loin followed by polyuria. For a short period he had noticed blood in the stools. An attempt was made to catheterize the ureters but I couldn't find any ureteral orifices. Roentgenograms suggested stones in the region of both kidney pelves. Nephrostomy on one side was decided on and possibly bilateral nephrostomy depending on the condition encountered at operation. During the incision for exploration of the left kidney much fluid poured from the loin wound on account of the edema and when the fascia transversalis was incised a big mass presented itself in the wound. This proved to be the kidney. An opening into the kidney pelvis directly through the parenchyma was made by means of a hemostat. Urine under considerable

pressure gushed from the nephrostomy wound. The kidney pelvis was explored but no stone could be felt. A rubber tube was inserted in the kidney and the loin incision was closed and an incision made in the right loin. The patient was so edematous on this side that I cut down where I thought the kidney was. It happened to be a little below the kidney pelvis and a greatly distended ureter came into view, so I stuck a hole in this sewed a catheter in the ureteral opening and closed the loin incision. The patient lived only about twenty hours after the operation. Autopsy revealed an ulcerating carcinoma of the sigmoid with stenosis with metastases to the peritoneum and retroperitoneal nodes to the liver and both ureters. Both ureters were completely occluded by the metastatic nodules. While comparatively few cases of bilateral metastatic malignant lesions of the ureters have been reported, attention has now been so focused on the condition that one should always bear it in mind as a possibility when bilateral ureteral obstruction is suspected.

DR. A. E. BOTHE, Philadelphia. A patient was first seen on account of hematuria, no other symptoms were associated. A pyelogram showed a filling defect. The kidney was removed, a tumor was found in the pelvis and a diagnosis of benign papilloma was made. About four years after removal of the kidney hematuria occurred again. At that time I found a papillary tumor protruding from the ureteral orifice on the side on which the kidney had been removed. The patient was advised to have irradiation and this was followed by ureterectomy. A photomicrograph showed that the tumor in this particular part was not infiltrating the wall of the ureter. This last removal was about a year and a half ago. He has had postoperative irradiation. Cystoscopy about a week ago gave no evidence of any tumor in the bladder and the patient is perfectly well.

DR. F. C. HERRICK, Cleveland. I readily appreciate involvement of the ureter from above down. The part of especial interest has been ascending growth in the periureteral lymphatics. It does not seem to me that there has been enough emphasis placed on this in the literature. I mentioned it twelve or fourteen years ago, since which time a pathologist called my attention to a prostatic carcinoma in which he had demonstrated metastatic growths in the ureteral wall and periureterally extending up to approximately the upper third of the ureter then leaving that point and going into the cortex of the kidney. That is along the line of the extension of infection as described by Schultz and Eisendrath. Since then I have seen perhaps four or five similar cases in the pathologic departments in Cleveland. The last two were carcinoma of the prostate and carcinoma of the cervix respectively in which periureteral, intramural ureteral extension of the growth was proved at autopsy with the growth implanted into the cortex of the kidney. That, to me, is very strong evidence of the ascending route. Along the line of infection transmission, in the past I had a patient with papillocarcinoma on the left side of the bladder, a small one, which I resected, following which it cleaned up very well. He was home a week when he had violent chills, high fever and a very tender, large left kidney. It was perfectly obvious that he had involvement of the left kidney. The local handling of the bladder had been resection, careful closure and drainage intracystically and in the deep pelvis on that side, the drain was removed in three or four days. There was no evidence of infection locally. He was taken back to the hospital and exposure of the left kidney was made. The fatty capsule in these cases is thick and edematous, it is a thick firm, inflammatory type of fat. Multiple abscesses were evident in the cortex of the kidney. A quick nephrectomy was done from which he recovered very nicely. All the infection and all the abscesses were cortical and just beneath the capsule of the kidney. That, together with the evidence from tumor metastasis, I cannot help but explain by ascending periureteral lymphatic extension.

DR. STANLEY R. WOODRUFF, Jersey City, N. J. I brought up this subject mostly for the reason that it affords another thing to think about in acute anuria. It has been customary to think that anuria is caused always by calculous disease, or possibly toxic nephritis. However, this condition must be thought of

MALIGNANT HYPERPLASIA OF THE LYMPH FOLLICLES OF THE SPLEEN

H RYERSON DECKER, MD
PITTSBURGH

AND

H G LITTLE, MD
WHEELING, W VA

In 1925 Brill, Baehr and Rosenthal¹ reported three cases of what they called splenomegalia lymphatica hyperplastica. Their observations and review of the literature led them to believe that there had been reported previously only one other similar case, that of Becker in 1901. Several cases were noted of splenic lymphadenosis in which there was lymphoid hyperplasia confined to the spleen and in which splenectomy had been performed.

In 1927 Dr R D Baker reported a case of splenomegalia with enlargement of the lymph nodes, notably the posterior auricular, occipital and inguinal. Biopsy showed giant lymph follicle hyperplasia. With roentgen treatment the glandular involvement receded, but the red blood cells and the bone marrow were damaged. The man died in 1930 and the case was finally diagnosed as chronic lymphatic leukemia.

It was our good fortune to study and treat a case in 1927 similar in most respects to the cases reported by Brill, Baehr and Rosenthal.

History—Mrs T R aged 28 reported for an examination in April 1927, because of a mass in the abdomen, which had been discovered by her family physician. For two months previously she had noticed a heaviness in the left side of the abdomen and an occasional shooting pain down toward the left pelvis. There had been a tendency to flatulence and constipation. She also had shortness of breath. She had been nursing continuously up until this time a 10 months old baby. Her weight was normal. The menses had been established three months after childbirth and were normal.

In childhood she had had diphtheria and scarlet fever and in 1915 an uncomplicated and moderately severe attack of typhoid. She had been married for five years and had two children, aged 3 years and 10 months, respectively.

The family history was essentially negative.

Examination—The patient was well nourished and slightly pale. She weighed 115 pounds (52 Kg.). The teeth were in good condition, the thyroid was small and the tonsils were submerged and normal. The eyes and ears were normal, the tongue was clean, and superficial lymph nodes were not palpable. The heart was normal, except for a soft systolic blow in the pulmonic area. The pulse was regular with a rate of 80. The blood pressure was 110 systolic 70 diastolic. The vessel walls were not palpable. The lungs were normal.

The abdomen was asymmetrical owing to the presence of a smooth mass in the left flank which had the characteristic contour of the spleen extending from the eighth left intercostal space above to the crest of the ilium below. It was slightly tender and slightly movable, especially from side to side. The right kidney was normal in size palpable and movable to the second degree. The left kidney was not palpable. The liver was of normal size. There was no free fluid demonstrable.

Examination of the blood April 4 showed hemoglobin 88 per cent, red cells 4,100,000, white blood cells 4,500, polymorphonuclear leukocytes 60 per cent, small mononuclears 25 per cent, large mononuclears 15 per cent, blood platelets, 197,000 bleeding time two minutes, coagulation time, six and one-half minutes. The Wassermann reaction was negative. The blood sugar was 90 mg per hundred cubic centimeters and the nonprotein nitrogen, 29 mg.

Urinalysis showed a cloud of albumin with a small number of granular casts, a few red and white cells and debris. This was confirmed in several examinations. Stool examination was negative for blood and ova.

The bladder was normal, a number 5 catheter was passed to both kidneys. Indigo carmine given intravenously appeared on the right side in two minutes, and on the left in three minutes. The urine from the right kidney was normal. Urine from the left kidney contained red blood cells and granular casts. A pyelogram showed both kidney pelvis normal. There was a prolapse of the right kidney.

Roentgen study of the gastro intestinal tract showed that the stomach was atonic, prolapsed and dilated, with a slight six hour residue. The meal reached the rectum in twenty four hours. The splenic flexure of the colon was prolapsed. The mass apparently had no connection with the stomach.

The urinary changes pointed to a lesion of the left kidney, suggesting the possibility of the tumor being an enlarged kidney. The physical and roentgen examinations, however, were quite conclusive of an enlarged spleen. It was impossible from the history and the physical examination to determine its etiology. An exploratory operation was advised and accepted.

Malignant hyperplasia of the lymph follicles of the spleen under low power

Operation—April 13, with nitrous oxide anesthesia and local procaine hydrochloride infiltration of the abdominal wall, an exposure through the left rectus muscle was made. The tumor was a spleen weighing 3½ pounds (1,587 Gm.). The external contour, color and consistency were normal. The peritoneal surface was smooth but marked by innumerable small yellowish white depressions. No peritoneal adhesions were found. There were three arteries and veins in the pedicle. Removal offered no technical difficulties.

The liver was a reddish brown. It was normal in size and appearance. The gallbladder was normal. There were two enlarged lymph glands in the gastrosplenic omentum. The larger, measuring 2 cm in its longest diameter, was removed for examination. No other enlarged lymph glands were seen anywhere. The pancreas was normal. The stomach was outwardly normal and not prolapsed. The small intestine and colon were normal. The appendix was atrophic and nonadherent. The kidneys were normal in size. The right kidney was freely movable. The pelvic viscera were normal.

Postoperative Course—Convalescence was entirely normal and uneventful. The abdominal wound healed by primary intention. The patient left the hospital, May 3 feeling well. Her weight was 110 pounds (50 Kg.). Examination of the blood on that date showed hemoglobin, 98 per cent, red blood cells 4,400,000, white blood cells 11,100, polymorphonuclear leukocytes, 79 per cent, small mononuclears, 15 per cent, large

¹ Brill N E, Baehr George and Rosenthal Nathan. Generalized Giant Lymph Follicle Hyperplasia of the Lymph Nodes and Spleen. J A M A 84 669 (Feb 28) 1925

mononuclears, 6 per cent, blood platelets, 222,000. The bleeding time was two minutes. Coagulation time was three and one-half minutes. Urinalysis subsequent to the operation was normal.

Since leaving the hospital, the patient has been enjoying excellent health. She gave birth to a third child, Sept 18, 1929. There was no development of enlarged lymph nodes. She now weighs 130 pounds (59 Kg).

Pathologic Examination (By Dr H G Little).—The spleen, weighing $3\frac{1}{2}$ pounds, measured 22.5 by 11.3 by 6.5 cm. It was a dark reddish brown, markedly increased in size, and firm, the capsule was smooth, save for a small area of perisplenitis. The surface was a reddish brown and the pulp moderately firm. Scattered throughout the surface were many small grayish nodules resembling miliary tubercles. There were no infarcts in the spleen. The sections showed without the microscope

they alone are involved in the disease process. It is, we feel, of malignant character and at the present time is classified as malignant hyperplasia. It is interesting to note that the patient has had three infectious diseases which usually involve the spleen. The inflammatory reaction seen in the sections may be induced by the tumor growth, as sometimes seen in a lymphoblastoma or by some infection. The prognosis would seem to be poor, because of involvement of a neighboring lymph node, yet tumors of lymphatic tissue respond splendidly at times to x-rays alone or to surgery and x-rays.

Sections of the tumor were sent to Dr G R Callender, Lieutenant Colonel, M C, U S Army, at the Army Medical Museum, for the lymphatic tumor

TABLE 1—Protocols of Cases of Malignant Hyperplasia of the Lymph Follicles of the Spleen

	Case 1 (Dr Baehr)	Case 2 (Dr Baehr)	Case 3 (Dr Baehr)	Case 4 (Herein Reported)
Age	23 years	32 years		23 years
Sex	Female	Female	Female	Female
Family history	Negative	Negative	Negative	Negative
Past history	Negative	Influenza 1 year before	Negative	Diphtheria, typhoid, scarlet fever
Onset	Glandular swelling of neck for $2\frac{1}{2}$ months; dyspnea, cough, increase in size of abdomen	Weakness, increase in size of abdomen and for 2 months heaviness		Heaviness for 2 months; flatulence, constipation, dyspnea
Physical examination	Left pleural effusion			
Lymph nodes	All enlarged, especially cervical—size of pea to walnut; discrete, not tender, movable	Axillary, epitrochlear, left inguinal moderately enlarged	General enlargement	Not enlarged
Spleen	Eighth left rib to anterior superior spine of ilium and 5 cm to right of midline; smooth, not tender	Eighth left costal space to brim of pelvis and within 2 cm of midline; smooth, nontender	Large	From eighth left costal space to crest of ilium; slightly tender and movable
Liver	Not enlarged	Greatly enlarged		Not enlarged
Blood				
Hemoglobin	72%	9%	75%	58%
Red blood cells	4,700,000	4,000,000	3,200,000	4,100,000
White blood cells	6,000	11,000	6,000	4,500
Platelets	160,000	105,000		107,000
Polymorphonuclear leukocytes	71%	42.3%	48%	60%
Large lymphocytes	15%	40.3%	46%	25%
Large mononuclear leukocytes				
Eosinophils	10	7	8	15
Basophils	8	1	2	
Neutrophils	0	0.3	1	
Treatment	Röntgen therapy, x-rays	Splenectomy, x-rays	Splenectomy	Splenectomy
Result	Spleen regained normal size; lymph node diminished; finally disappeared by second course of irradiation; patient well September 24, $1\frac{1}{2}$ years after treatment; died February 1930 with mediastinal infiltration	Followed by lobar pneumonia, subphrenic abscess, typhoid; enlarged lymph nodes disappeared in 3 months; recurred and disappeared with x-rays; patient well January 1932, 20 months after splenectomy	Died after splenectomy	Removal of two glands in gastro-omental; no further lymph node enlargement; patient well July 1935
Pathologic changes	Spleen: huge malpighian bodies roughly size of barley grain; follicles greatly enlarged; little intervening pulp; lymph sinuses obliterated by compression; cells endothelioid looking like lymphoblasts; lymph nodes corresponded grossly and microscopically to splenic changes			Spleen, weight $3\frac{1}{2}$ pounds; innumerable grayish nodules resembling miliary tubercles (microscopically); follicular hyperplasia; lymph node corresponded grossly and microscopically to splenic changes

large hyperplastic follicles. With it the increase in the size of the follicles was seen to be due to a fairly compact cellular growth of the cells in the germinal centers. The cytoplasm of the cells was pale staining and delicate. The nuclei showed a moderate amount of chromatin and some nuclei were clear except for one or possibly two large well defined nucleoli. This cellular hyperplasia was taking place in every follicle in the section and in some areas new foci appeared to be developing. Although the follicles dominated the picture, there was an associated hyperplasia of the lymphoid cells in the reticulum. Occasional mitotic figures were seen. A moderate number of polymorphonuclear leukocytes and an occasional eosinophil were found. There was no evidence of tuberculosis in the sections. The section of the lymph node showed a picture similar to that in the spleen.

The growth was different from the sarcomatous type of lymphoblastoma. Although the extremely large follicles dominated the picture, we do not believe that

registry. He commented that in 1929 it was the only case in the registry that showed a similar picture in both spleen and lymph nodes and that because of this dual involvement the prognosis was very poor. He wrote further: "The classification of such a case was very difficult, and I think hyperplasia, to distinguish it from definite sarcomatous reaction, is justified at present."

In a recent communication he² writes:

Your case has been classified under the nodular type of leukemic lymphocytoma described originally by Symmers as giant follicular hyperplasia with splenomegaly. There are twenty-three cases in the registry now with this diagnosis, fourteen are living, eight are dead, and one has been lost track of.

² Callender, G. R. Personal communication to the authors from Fort Sam Houston, Texas.

Dr Baehr,³ in referring to this disease, has commented as follows

The tumor differs from ordinary lymphosarcoma in that it produces follicles and is multicentric in origin. The clinical picture is also quite different from lymphosarcoma, unilateral exophthalmos due to orbital infiltrations occurring commonly, as well as scattered involvement of the lymph node and lymphatic tissue in various parts of the body. There is no tendency to anemia or cachexia. The importance of differentiating these cases clinically and pathologically from ordinary lymphosarcoma is the fact that they respond so promptly and effectively to radiotherapy. I have seen mediastinal infiltration, which is large enough to choke the patient almost to death, begin to disappear after a few exposures to one fifth of an erythema dose. The oldest case under observation at present has lasted over ten years. Another case which I reported in 1925 died this morning, Feb. 14, 1930, as a result of mediastinal infiltration which had been neglected. The large splenomegaly, which in 1924 had disappeared completely under x-ray therapy, reappeared for the first time several weeks ago. The hydrothorax, which had brought the patient to me in 1923, also had reappeared. There seemed to have been a fulminating relapse, and death occurred before the radiotherapy could accomplish much. The prognosis is far better than with other malignant neoplasms because of the remarkable radiosensitivity. The patient should be constantly under observation so that the first recurrence of lymph node enlargement anywhere in the body should be promptly treated.

Protocols of the cases referred to by Dr Baehr are given in the accompanying table.

With present knowledge it may be said that the etiology of this hyperplasia of the lymph follicles of the spleen is unknown. It seems very definitely to be a neoplastic process, although its kinship to lymphosarcoma, as Dr Baehr says, is far from established.

The symptomatology is concerned with the enlargement of the spleen. If there is mediastinal glandular involvement, or pleural effusion, there may be dyspnea and cough. Enlargement of the spleen comes gradually over several months and causes a heavy feeling but not characteristically any pain. There is no loss of weight and no cachexia. There is apt to be secondary anemia but nothing characteristic in the blood picture.

The diagnosis will be established with certainty only by pathologic examination of the lymph glands or the spleen. It will not be confused with the splenic enlargements of the blood dyscrasias such as leukemia, hemolytic icterus, purpura haemorrhagica and polycythemia vera, in which the blood picture and reactions are characteristic, nor will the enlargements of the specific infections such as syphilis, tuberculosis, typhoid, and malaria be hard to distinguish. The splenomegaly of the so-called splenic anemia will be more difficult to differentiate, particularly in the early stages before gastric hemorrhage and enlargement of the liver or severe anemia develop. The splenic enlargement of Gaucher's disease may likewise cause difficulty. Tumors of the spleen such as benign lymphomas and lymphosarcomas will defy differentiation clinically at the outset.

Individuals with this disease untreated either die rather quickly or, if life is prolonged, develop ultimately fatal sarcomatous changes in the lymph glands and spleen with metastasis. With treatment, life may be prolonged many years, if undertaken early enough and adequately, a cure of the disease may be effected.

TREATMENT

Two courses of treatment are open: roentgen therapy and splenectomy. Both have been successful. Apparently roentgen irradiation will restore the spleen to

normal size and cause lymph node enlargement to disappear. There are no data to show that this primary effect is permanent. On the contrary, it would seem that there is need of repeating at intervals a course of irradiation to the spleen and various groups of lymph glands. Particularly must the mediastinal nodes be watched.

In our case, splenectomy alone served to effect a cure, that is, the patient is living and well at the end of nearly eight years. It was striking in this case that there was no enlargement of the lymph nodes on the exterior of the body, and that intra-abdominally only several immediately adjacent to the spleen were found. This suggests that metastasis to the lymph nodes takes place slowly and only after the primary splenic hyperplasia is well developed. Possibly successful treatment in this case is linked definitely with the fact that at the time of the splenectomy there had not been metastasis or development of the process in the peripheral nodes.

Provided there was no specific contraindication to operation, in another case we should be tempted to do a splenectomy first and then treat the lymphatic system by irradiation as need be. In absence of lymphatic enlargement suitable for biopsy, it will be necessary to examine the spleen itself to establish the diagnosis. Irradiation should be deferred until this is done.

THE TREATMENT OF MILK ALLERGY AND ITS BASIC PRINCIPLES

BRET RATNER, M.D.
NEW YORK

Hypersensitiveness to milk presents a problem of general interest, although it may be of more immediate concern to the pediatrician. Its manifestations are many and include conditions varying from the mildest to the most severe forms of gastro-intestinal disturbances, eczema, urticaria, asthma, mucous colitis, migraine, acne, marasmus and pylorospasm. The foreign literature particularly has been replete with studies by such eminent pediatricians as Schlossmann, Finkelstein, Hutinel, Finizio, Barbier and Weill-Halle, who have stressed the importance of the consideration of milk allergy in the field of infant feeding and who have cited cases which have eventuated either in most severe shock reactions or even acute anaphylactic death from the ingestion of milk. Moro¹ and Bauer² first described cases of marasmus due to milk intolerance and showed that this condition could largely be attributed to immunologic disturbances resulting from the entrance of the milk proteins into the blood stream. Schloss and Worthen, and Anderson and Schloss³ in America amplified this concept. More recently, in the French monograph of Laroche, Richet and St. Girons and in the excellent and more complete textbook on food allergy by Rowe⁴ of California, emphasis was

laid on the fact that allergy to milk is encountered more frequently than most physicians are aware of, not only in early infancy but well on into adult life. Space does not permit a fuller presentation of the clearly proved evidences of idiosyncrasy to milk, but suffice it to say that the insidious influence that the ingestion of raw milk proteins must have in human afflictions is great indeed and not often enough recognized or adequately understood.

PATHOGENESIS

Many theories have been advanced to account for the development of allergy, and it would necessitate a wide digression to consider all the factors that have been proposed in explanation. There are in the main two schools of thought, one proposing that it is inherited, the other that it is acquired. My own experience leads me to stand with the latter school. The following discussion of the pathogenesis evolves from factual evidence gathered from clinical observation and laboratory experimentation.

A Congenital Sensitization—1 **Passive Sensitization in Utero** It has been demonstrated by Rosenau and Anderson, Wells and many others⁵ that a fetus can be passively sensitized in utero. In relation to the human infant, such passive sensitization would occur only when the mother was sensitive to milk, the fetus being sensitized by the transfer of milk antibodies through the placenta. This phase I believe plays a minor role.

2 **Active Sensitization in Utero** With the cooperation of Professor Jackson and Miss Gruehl I⁶ published a series of studies showing that a guinea-pig fetus can be actively sensitized in utero, by which I mean that the specific antigen is transferred from the pregnant female to the fetus through the permeable placenta, and antibodies to this antigen develop after birth. This observation laid the groundwork for a clinical study in which I⁷ postulated that a pregnant woman indulging excessively in protein foods during the latter months of pregnancy could actively sensitize the human fetus to the particular food, or foods, consumed to excess. Up to that time there had been no valid explanation for those instances in which infants manifested allergic reactions on taking milk or other protein foods for the first time.

B Sensitization Through the Gastro-Intestinal Tract—Rosenau and Anderson, Richet, Ascoli, Wells and others⁸ showed that proteins administered orally can pass directly through the intact intestinal wall and enter the blood stream. Walzer⁹ demonstrated this in the human adult with fish and egg proteins, and Anderson, Schloss and Myers¹⁰ in the normal infant with milk, egg and almond. More recently Ratner and Gruehl⁵ showed that milk proteins fed to guinea-pigs entered the blood stream with such frequency that they contended that such a passage is a normal phenomenon. Duke and Stofer¹¹ cited the remarkable case of a donor

who drank a considerable amount of milk before his blood was used for a transfusion. The recipient, a woman aged 63 who was allergic to milk, had a violent allergic reaction that may be attributed to the milk proteins circulating in the donor's blood.

In our study we⁸ have indicated that although the intestinal wall is normally permeable to proteins, abnormal conditions may increase its permeability and may account for sensitization in the following circumstances:

3 An occasional feeding of raw milk during the new-born period, when the intestinal wall is naturally more permeable, may give rise to a state of hypersensitiveness which is manifested when the child is later given raw cow's milk either to supplement breast feeding or when it is weaned from the breast.

4 Periods of excessive ingestion of raw cow's milk followed by periods of complete abstinence may also result in sensitization.

5 In persons who are fed raw milk during convalescence from some disease or during and after severe gastro-intestinal disturbances, hypersensitiveness may develop.

C Sensitization from Parenteral Injections of Milk—This is illustrated by the case reported by Lubiner,¹² who described a nearly fatal reaction following the intramuscular injection of 10 cc of milk into a girl eight days after the last of three daily injections. Many other cases have been reported.

IMMUNOCHEMISTRY OF MILK PROTEINS

According to Wells and Osborne¹³ milk contains four distinct proteins, or protein fractions, namely, casein, lactalbumin, lactoglobulin and an alcohol-soluble protein. By immunologic means, particularly the anaphylactic test, it has been shown that these four proteins are immunologically distinct. Of the four proteins only globulin is related to the beef serum, but the lactalbumin and the serum albumin are two distinct proteins. Biologically casein is as distinct from the whey proteins and serum proteins as it is chemically, whereas the biologic reactions of caseins from the different species of animals show close relationships. The albumins, however, differ immunologically in the various animal species. To recapitulate, therefore, casein represents a protein that is common antigenically in the milks of various animal species, lactoglobulin is a counterpart of the serum globulin from the same animal and is species specific, and lactalbumin stands alone as an independent protein, foreign to the blood stream and not related to the casein and is species specific.

One of the fundamental principles relative to the chemistry of proteins is that a protein cannot induce sensitivity or shock reactions in a sensitized human being or animal unless it is at once readily soluble and in a native or unchanged state. It must be soluble in order to pass through living membranes and enter the blood circulation to reach sensitized smooth muscles in the various organs, and it must be native or unchanged because the higher degradation products of the proteins, which result from proteolytic digestion, namely, the polypeptides, proteoses and peptones, and the completely hydrolyzed constituent amino acids, have all been shown to be incapable of serving as sensitizing or shock-producing substances. When milk enters the digestive tract, it undergoes a precipitation or curd formation

of the casein fraction which results from contact with the rennin and hydrochloric acid present in the stomach. The whey substances—containing the lactalbumin and lactoglobulin fractions with the carbohydrate and mineral constituents—pass unchanged through the pylorus and enter the small intestine. The precipitated casein then gradually leaves the stomach and enters the small intestine, where the digestive enzymes further act on it, there is small likelihood that this precipitated protein is in a sufficiently soluble state to escape through the intestinal wall into the blood stream before it is partially or even completely digested. This is not so with the whey proteins, which are still in a liquid state and highly soluble, it is conceivable that they may escape digestion and thus enter the blood stream before digestion alters their nativity and serve as anaphylactogens.

Other factors that may change the antigenic properties of the milk proteins will now be considered.

A Heated Milks—Wells¹⁴ observed that casein heated to 100 C for twenty-five minutes did not lose any of its anaphylactogenic properties. Cutler¹⁵ using the precipitin and complement fixation methods and anaphylactic test, more recently concluded from a study of raw, pasteurized and evaporated milks that in evaporated milk there is a 50 per cent reduction of the whey protein, and that there is a chemical change in specificity of these proteins. Lewis and Hayden¹⁶ included smaco 303 in their study and employed the complement fixation test. All these investigators agreed that heat does not change the antigenic properties of casein, although Lewis and Hayden found that it begins to show a slight change when the heat reaches 100 C. All these investigators were in agreement on the fact that the whey proteins are specifically changed chemically by the process of heat and evaporation, and the latter indicated that the change occurs when the heat reaches 60 C.

I believe that these investigators have erred in concluding that a chemical change of specificity occurs as a result of the application of heat, which position we¹⁷ have discussed in a recent paper on our study of the influence of the various heat processes on the anaphylactogenic properties of milk. We worked with purified proteins, whereas Cutler, Lewis and Hayden merely crudely separated the whey from the casein fraction. We have shown that unless the milk proteins are most exactly purified they are always contaminated one with another. All the so-called pure caseins that we obtained from reliable sources gave marked reactions when tested against lactalbumin.

Casein is unaffected by the evaporation process and other forms of prolonged application of heat. We found no specific chemical change in any of the protein fractions as a result of the influence of heat, we sensitized animals with milk boiled for several hours, evaporated and superheated milks and shocked them with pure lactalbumin obtained from raw milk. But when we sensitized animals to pure lactalbumin from raw milk, we were unable to shock them with heated milks. We therefore concluded that the only change which

occurs in the heated milks is a physical one, namely, coagulation of the whey proteins, which markedly diminishes the ability of the milks to induce anaphylactic or allergic reactions in human beings or animals sensitized to lactalbumin and lactoglobulin. In those of our experiments in which the antigen was administered orally to animals the diminution of the properties of sensitization and shock of heated milks was strikingly demonstrated.

B Dried Milks—We studied the antigenic changes that result from varying drying processes applied to milks and found that the rapid drying—which is almost instantaneous—did not influence or diminish the antigenic powers of the milk proteins. It is interesting to note that Hart, Steenbock and Ellis¹⁸ showed that vitamin C still remains potent in dried milks. This vitamin is destroyed in evaporated or superheated milks. Since the milk in the drying process is not subjected to heat for a long enough period to affect the highly heat-labile vitamin C, our contention that the drying process does not influence the antigenic powers of the proteins is further supported. Chick and Martin¹⁹ also showed that in order for coagulation to take place the proteins must be in a liquid state and that proteins that are dry resist the influence of heat.

C Acidified Milks—We found that acidification of milk in no way diminished the anaphylactogenic properties and as a matter of fact enhanced them. In our feeding experiments we succeeded most easily in sensitizing the largest percentage of animals with acidified raw milk. An explanation may be that just as in digestion the formation of the curd liberates the whey proteins and makes them more accessible for absorption into the blood stream. This is borne out by the fact that the lactalbumin as it exists in fresh raw milk is in such a condition that only a part passes through a porcelain filter, however, when the milk is acidified the lactalbumin is completely filtrable through the porcelain filter.

Before proceeding to a consideration of the treatment it may be helpful to evaluate the relative importance of the individual milk proteins as causative agents in milk allergy. From Hutinel, Barbier, Weill-Halle and others it is learned that practically every patient with an idiosyncrasy to milk, no matter how severe, can be relieved from further allergic manifestations when taken off cow's milk and given goat's, ass's or human milk. In view of the independence of the lactalbumin and lactoglobulin fractions of the milks of the various animal species and the close relation of the casein fractions, one is forced to the conclusion that most of these persons, if not all, are sensitive to the whey proteins and not to the casein fraction. In those cases that are reported in the literature in which positive reactions to casein are shown one is faced with the difficulty, into which we have gone at such length, that the investigator may not have been using a truly purified casein, in this category must be placed such a publication as that of Anderson, Schloss and Stuart²⁰. It must again be emphasized that the casein fraction is curdled by contact with the gastric juices and thus impeded from entering the intestinal tract in a soluble form. This is

not true of the whey proteins. From such reasoning it should follow that persons are more readily sensitized to the latter proteins. An interesting speculation is that in infants who have been breast fed a tolerance for the casein fraction develops which is antigenically related both in human and in cow's milk. From this brief summary it becomes apparent then that the treatment of intolerance for milk must be focused on the sensitivity to the soluble whey fractions. The points made here are interestingly illustrated in the following case. We believe that this case is unique in that purified proteins were used for testing purposes.

REPORT OF CASE

A boy who was 9 years old when I first saw him had been sensitive to cow's milk from early infancy. He was breast fed for eighteen months because when first given cow's milk he had a severe allergic reaction with vomiting and urticaria. When milk was subsequently given he had severe attacks of asthma even after taking only a few drops. The physician who studied this case for several years attempted to build up a tolerance for milk by giving drop doses yet when the child was finally given one teaspoonful of milk he had a severe asthmatic attack with cyanosis, milk that was used in the preparation of foods provoked a reaction. The child was brought to me two years ago and the father was so insistent that milk was toxic for the child that he would not permit me to make a clinical trial with even a drop of milk. Tested by the scratch method, the child showed a moderate reaction to lactalbumin and to whole cow's milk. He was tested intracutaneously with the purified lactalbumin and casein (used in our experiments) in doses of 0.02 cc. of a 1 per cent solution of lactalbumin and with a similar dose (0.02 cc. of a 28 per cent solution) of casein. There was absolutely no reaction to the casein, but within a few minutes after the test with lactalbumin there developed a severe asthmatic attack with marked cyanosis and moderate dilatation of the right heart, and the child appeared to be going into anaphylactic shock. Restorative measures were applied, and epinephrine and oxygen administered. The boy remained in shock for several hours. The asthmatic phase continued for four days.

Serum taken from this patient and transferred to five guinea-pigs induced passive anaphylaxis in two of the animals. His serum was also transferred by the Prausnitz-Küstner method to the skin of several normal children and the presence of lactalbumin antibodies was demonstrated. One normal girl of 12 years, whose skin was locally sensitized, abstained from milk for forty-eight hours and was then given a glass to drink, a strongly positive local cutaneous reaction developed twenty minutes after ingestion. All these cases of passive local transfers were shown to be due to lactalbumin antibodies in the blood and not to casein. It may be noted that although raw milk in the smallest quantity provoked asthmatic attacks, and a minute amount of lactalbumin injected intracutaneously induced anaphylactic shock, this child was able to take reheated evaporated milk in normal amounts without the slightest reaction.

BASIC TREATMENT

In a case of milk allergy the first necessity is to eliminate all forms of whey proteins including raw milk as a beverage, milk used in the preparation of foods such as bread cake cream sauces, desserts, ice cream and cream of rice, and butter, dried milks, acidified raw milks, rare beef and beef serum.

The next problem is the substitution of some other form of milk. It has been stated that neither dry, acidified nor pasteurized milk nor milk boiled for a few minutes is of any true value in the treatment of patients with milk allergy. There is no uniform and perfectly standardized nonallergic milk. The only form that is valuable for substitution at the present time is that suggested by Kerley, who stated that milk boiled for

from three to six hours is well tolerated. However, this is an irksome procedure and the commercial equivalent—evaporated milk—can readily and reasonably be purchased. However, it must be warned that evaporated milks are not standardized and that not all kinds are subjected to an adequate amount of heat. When evaporated milk is used in a severe case of milk allergy, it should be boiled vigorously for several minutes just prior to use. It is rather interesting at this point to note that Marriott, who originally advocated the use of acidified whole raw milk in infancy—which we have shown to be highly anaphylactogenic—later advocated the use of acidified evaporated milk. Denatured heated milk may be given to the milk intolerant infant in amounts adequate for nutrition, and to it may be added the proper carbohydrate requirement in the form of dextrinmaltose or corn syrup, which we²¹ have shown are nonanaphylactogenic.

In the early investigations goat's, ass's or human milk was suggested as a substitute for cow's milk, but these are not necessary if evaporated milk is used. It has also been recommended that the child who is acutely sensitive to milk should be given no milk, but broths, cereals and vegetables. More recently Hill and Stuart²² advocated the substitution of a soy bean preparation. It is evident from this work and that of Tso²³ that soy bean can replace milk and that it fulfils the nutritional requirements of the child. However, while relief is obtained by such substitution, a tolerance for milk proteins is not built up. The child remains just as sensitive to the milk during and after the period of substitution by these foods as he was before their use. Since milk enters so largely into the diet of the adult as well as the child, I believe that an attempt should be made to build up a tolerance to milk proteins and that there should be no delay in attempting the ultimate cure of the intolerance for milk.

In view of the fact that we have shown that thoroughly heated milks are merely changed physically and that the chemical structure of the whey proteins still remain unchanged, such heated milks may be used indefinitely provided an adequate amount of vitamin C—which is the only factor destroyed—is added to the diet. It is believed by many pediatricians, among them Kerley and Brennemann, that heated milks have greater nutritive value because they are more readily digested and assimilated. With the use of heated milk and the complete elimination of all milk-containing foods one is ready to proceed with immunization by giving drop doses—or even a fraction of a drop—of raw cow's milk each day orally as Schloss,²⁴ Park²⁵ and I²⁶ have advocated. The quantity is very slowly and gradually increased, depending on the tolerance of the patient, and after a period of from six to nine months a normal amount of raw milk can generally be taken. From then on, as has been emphasized by French investigators, milk must be given continuously throughout the rest of the person's life in moderate amounts, either as a beverage or in foods.

Summarizing, the treatment of milk allergy consists in

- 1 The elimination of all raw milk from the diet, including milk used in the preparation of foods
- 2 The substitution of a milk subjected to intense and prolonged heat in a liquid state
- 3 The gradual immunization of the patient by the oral administration of minute amounts of raw milk, with the continued use of the denatured milk throughout the entire period
- 4 The final substitution of adequate amounts of raw milk, which must be taken from then on continuously in moderate amounts

THE PREVENTION OF MILK ALLERGY

As important as it is to understand and treat patients with milk allergy properly, it is even more important to attempt to prevent the onset of the condition. I believe that this can be accomplished

- 1 By advocating the taking of moderate amounts of milk during the period of pregnancy and the careful curbing of excessive indulgence in raw milk during the latter months of gestation so as to avoid the possibility of inducing congenital sensitization. If milk is desired in more than moderate amounts, part of the consumption should be in the form of denatured milk.
- 2 By avoiding isolated feedings of raw cow's milk to the breast fed infant during the new-born period
- 3 By giving no raw cow's milk during convalescence from disease and during and after gastro-intestinal disturbances
- 4 By refraining from the use of excessive and exclusive milk diets
- 5 By elimination of the use of injections of milk for non-specific therapy

SUMMARY

Hypersensitiveness or allergy to milk is of more frequent occurrence than is generally realized and not only causes mild symptoms but may even result in acute anaphylactic death. It occurs in adult life as well as in infancy and childhood. The soluble whey proteins of raw cow's milk, lactalbumin and lactoglobulin, are most often responsible for this condition, casein plays a negligible role. The pathogenesis, which is accounted for on the basis of acquisition and not of inheritance, suggests preventive measures. The treatment consists in the elimination of raw milk from the diet, replacement of it by denatured milk, and the establishment of tolerance by the slow and gradual introduction of raw milk.

515 West End Avenue

ABSTRACT OF DISCUSSION

DR. CHARLES G. KERLEY, New York. I am convinced that inheritance is a great factor in many of the cases and I have observed it repeatedly when it had been acquired congenitally through the use of foods by the mother. I believe that the allergic state constitutes a condition of systemic inferiority, a familial disorder due to an endocrine imbalance. The wide variety and the combination of allergic manifestations may be explained only through a common physiologic deficiency constituting an entity. I will give one instance out of many for my conclusion that there is a preallergic state. A mother reacts to milk. By a milk reactor I mean an individual who is made acutely or chronically ill by the use of raw milk. I have known milk reactors through four generations: mother, daughter, grand-daughter and great grandson. In infants and children it is through the nervous system that the most urgent evidence and signs are produced. I divide my allergic responses into four groups. First is the shock group. In one of my alarming cases, shock was by contact. I placed seven drops of milk on the tongue of a baby, aged 3 months. In a few seconds shock was extreme: slow respiration, extreme pallor and heart sounds were absent. It was with the greatest effort

that she was resuscitated. I have seen one case of death from shock in a baby of 10 months. It came time to wean the baby and 2 ounces of milk was forced on it. The child immediately went into collapse and when I came on the scene the child was pulseless, unconscious and in extreme shock. It died in spite of every effort. The lesser divisions were those of allergic response because the milk, disagreeing with the child, produces gastro-intestinal disorders, colic and reactions other than those related to the gastro-intestinal tract, notably eczema. In giving up cow's milk it is either a matter of goat's milk or human milk in the shock cases, and of heating of milk in the ordinary gastro-intestinal type and the eczema. A greater degree of desensitization is produced in eczemas and in cases of milder reactions of a gastro-intestinal nature by prolonged heating. Better results are obtained from two or three or four hours oftentimes than from one.

DR. SAMUEL GOLDBERG, Philadelphia. Because of the increased amount of knowledge of the body response to the various food proteins, particularly those found in milk, we as clinicians are probably often baffled as to how to apply it to our daily pediatric practice. One has only to glance through that excellent critical review by Francis Scott Smith in a recent issue of the *Journal of Pediatrics* to see how varied are the studies of animal experimentation and how different the observations and results obtained. Pirquet and Schick probably pioneered our idea of allergy, but in the last few decades there has been a general awakening to its importance and to the part it plays in our knowledge of disease and bodily response. I feel that there probably exists too great a gap between the students of allergy and the pediatrician or internist. I feel that there must be a closer bond between fundamental studies made by such enthusiastic workers as Dr. Ratner and the clinical interpretation given to it by clinicians at the bedside. Dr. Ratner, by his case report of the 9 year old boy, has shown that the skin reaction to the various proteins, on which so much stress is laid, is definitely inadequate to serve as a guide in this complex problem. He has shown that this boy, who was negative in his skin reaction to casein and only moderately active to lactalbumin by the intradermal test, was so acutely sensitive to lactalbumin as to have symptoms of collapse and shock. Here this minute amount of protein produced only a faint reaction in the skin and yet was sufficient to produce a shock reaction in the lungs. There is a tendency to regard these cases as allergic and too often one steps aside from them and refers them to other men, who are studying them from the standpoint of protein sensitivity alone. The importance of most detailed history and clinical study is perhaps being overlooked. If this were done, it would lead to a better understanding of familial strains, environmental influences, neurogenic factors and the part that internal glandular secretions play in regulating the blood mechanism and peculiarities. I make this plea for more careful pediatric study of these cases not to minimize the work of Dr. Ratner and similar observers but to incorporate it into everyday clinical bedside study, so that it may not be lost.

DR. ALBERT H. ROWE, Oakland, Calif. Dr. Ratner's conclusion that apparent casein allergy is usually due to traces of soluble milk proteins will need clinical consideration. In my work, those patients markedly sensitive to milk have not been able to tolerate even evaporated milk without mild or severe symptoms. Emphasis on beef elimination is necessary in certain patients, and also butter at first. In such cases a soy bean substitute, almond milk or goat's milk has been used in children, and in adults prolonged and complete elimination has been the rule. My experience assures me that milk sensitization is especially common in infancy and childhood and occurs in unappreciated frequency throughout life. In adults it may persist in a potential form. Its original manifestation, be it gastro-intestinal, cutaneous or bronchial allergy, often disappears or diminishes to reappear in later years in similar or different manifestations, such as migraine or toxemia. As with allergy to any food, that to milk may also establish itself in middle life or even in old age from causes such as overindulgence in the food, intermittent ingestion or its consumption during digestive upsets. Especially important of realization is

the frequency of negative skin tests to milk and other food proteins. Thus, of course, emphasizes the necessity of trial or elimination diets in many patients suspected of such allergy. The frequency of concomitant allergies to other foods and the possible development of inhaled allergies as months and years advance must be remembered. However, the tendency to develop either food or inhaled allergy may persist alone throughout life and seems to be intensified by inheritance. Likewise the tendency to develop specific manifestations, such as eczema, migraine or gastro-intestinal, nasal or bronchial symptoms, tends to run in families.

DR. GEORGE PINESS, Los Angeles. The question of heredity as discussed by Dr Ratner this morning does not disprove the theory of the heredity factor in allergy even though he is able to sensitize individuals to milk. The inability to disprove heredity as a factor in the allergic individual is due to the individual's lack of knowledge of his family history. This is particularly true in the clinic cases and not uncommon in private practice. Therefore one should not be too prone to question the theory of heredity. The question of boiling, evaporating and altering milk has proved to be a real problem to all of us who do allergy, in that we find that results can be obtained in some cases with every type of alteration of milk, whether by boiling or by evaporating. The question of milk sensitivity has attracted my interest particularly in eczema in children in whom there was a seasonal incidence of symptoms. I am now investigating the possibility of some relation to the fodder of the cattle from which the milk is derived. Milk sensitivities that clear up spontaneously have been most difficult to explain in that despite any method of treatment they will clear up but later show some other type of allergy. I believe that most spontaneous cures are the result of self desensitization due to the patient refusing that particular substance or food in his diet which causes these reactions.

DR. FRANKLIN P. GENGENBACH, Denver. Finkelstein, more than twenty five years ago, showed that infants tolerated a combination of cow's milk casein combined with breast milk whey better than they did breast milk casein combined with cow's milk whey. Also, he was able to cure temporarily the skin manifestations of eczema in bottle fed infants by taking out the whey from the cow's milk. It might be interesting to learn from Dr Ratner, in making his skin tests for milk sensitivity, the percentage of positive reactions that he gets to whole milk, casein and lactalbumin, and also whether there is any marked difference in the reactions between his scratch tests and intradermal tests, realizing, of course, that, in cases which show marked reaction to the scratch test, he probably would omit the intradermal test.

DR. BRET RATNER, New York. Dr Kerley's cases of transmission from mother to daughter seem to bear out clinically my experimental observation that this transmission has gone through the placenta and not through the germ plasma of the male, so that I would regard those apparent cases of inheritance as actually congenital that is, acquired in utero. The remarks of Dr Piness about inheritance, I think, are consonant with mine. The one fact I am certain of is that inheritance has not been proved scientifically to be a factor. So far as allergy can be acquired, I am sure that the inheritance factor may be placed in the background. It must be realized that these conditions are due to the entrance of antigens and that measures are at hand for their prevention. With reference to the cow's fodder, I think that it is of interest and that if a child does become sensitive to cottonseed or corn in this manner, boiling of that particular milk will certainly rid it not only of the anaphylactogenic lactalbumin but also of these extraneous substances. I have nothing to add to Dr Goldberg's remarks. With reference to the discussion of Dr Gengenbach, I was most interested in looking up the old literature of the Viennese and French pediatricians, and I was astonished to see how much further advanced they were in an understanding of milk allergy than are the pediatricians of today. Anaphylaxis was discovered about 1902 and probably the subject was fresh in their minds in the years 1905, 1910, 1912 and 1914. I believe that my experimental observations bear out the clinical observations they made.

TREATMENT OF ACUTE AND CHRONIC BRUCELLOSIS (UNDULANT FEVER)

PERSONAL OBSERVATION OF ONE HUNDRED CASES
OVER A PERIOD OF SEVEN YEARS

FRED E. ANGLE, M.D.

KANSAS CITY, KAN.

In 1859 Marston¹ described a disease syndrome which he named Mediterranean or gastric fever. In 1886 Bruce² isolated an organism, which he called *Micrococcus melitensis*, from the spleen of a patient who was a victim of this disease. In 1897 Bang³ isolated the organism which is the recognized cause of contagious abortion in cows. This organism is now called *Brucella abortus*. In 1914 Traum⁴ isolated an organism which is now called *Brucella suis*, from the fetus of an aborting sow. Thus, three strains of *Brucella* now have been recognized. In 1918 Evans⁵ suggested that these organisms were very closely related, both serologically and bacteriologically, and that *Brucella abortus* in all probability could infect man. In 1924 Keefer⁶ isolated *Brucella suis* from a so-called case of Malta fever, and in 1925 Duncan⁷ first isolated *Brucella abortus* from man. It would be impossible to state the actual number of persons infected with the various strains of *Brucella* occurring in the United States. It is, however, a statistical fact that 9,965 cases were reported up to Jan. 1, 1935, and that the disease is increasing.

CLINICAL SYMPTOMATOLOGY

Five clinical types have been commonly recognized: intermittent, ambulatory, undulatory, malignant and subclinical. However, I find considerable difficulty in classifying under these headings the 100 cases that I have observed. In many of these cases the symptomatology is so varied that any grouping is most difficult. Two general types may be recognized: (a) an acute type, arbitrarily defined to include those cases which run their full course, with or without treatment, within three or four months, and (b) a chronic form, in which symptoms persist for a longer period. Acute *Brucella* infection is characterized by fever, weakness, sweating, chilliness, occasional rigor and some form of pain, such as headache, backache and arthritic or abdominal pains.

These symptoms associated with anorexia, constipation, nervousness and occasional cough would suggest the diagnosis of brucellosis. If the disease is prolonged, there is also associated loss of weight and evidence of neurologic toxemia.

In chronic brucellosis, a part or all of these symptoms are present, but the neurologic symptoms become more manifest, and in my experience the majority of complications occur in this group. Evans⁸ has recently pointed out the importance of the neurologic manifestations of this disease and that, before the diagnosis

of chronic neurasthenia or psychasthenia is made, the possibility of chronic brucellosis should be considered.

Brucella has been recovered in pure cultures from a large variety of suppurative lesions, such as meningitis, salpingitis, purulent orchitis, empyema, purulent cholecystitis, acute spondylitis with abscess formation, and acute mastitis. Cultures taken from these lesions in the average clinical laboratory will give negative results because of the difficulty in growing *Brucella*. This organism in all probability has been a hidden causative agent in many so-called sterile abscesses.

LABORATORY DIAGNOSTIC AIDS

Laboratory data are invaluable as aids for diagnosis and prognosis in brucellosis. Early in my study I believed that agglutination in a dilution of 1 to 80 was necessary to confirm a diagnosis. But I know now that, even when the agglutination titer is low or absent, the patient may be a victim of this disease. Since 1932 I have employed a skin test as a confirmatory aid in diagnosis when there was very strong clinical evidence in the absence of agglutination. This is performed by the injection of from 0.02 to 0.04 cc of *Brucella* antigen intradermally, another patient or the laboratory assistant being used as a control. Any vaccine on the market is a suitable antigen for the performance of this allergic reaction. I have been able to recognize six cases included in this group by this method. Simpson⁹ states that the agglutinins are absent in the blood stream in 5 per cent of the cases.

Blood cultures for the isolation of strains of *Brucella*, as performed in the average laboratory, are unsatisfactory because of the difficulty in securing proper mediums and equipment. Diagnosis by culture is delayed because it is recognized that cultures should not be reported negative until incubated for a period of thirty days. A leukopenia is usually present. Eighty-five per cent of this group of patients presented a white blood count of less than 6,500. In the differential smears, 90 per cent of this group presented a relative lymphocytosis and 65 per cent showed a definite increase in mononuclear leukocytes. Some degree of secondary anemia was shown in 87 per cent. Huddleston¹⁰ suggested the additional laboratory test of opsonocytophagic power of the blood. I believe that this test is quite reliable, but I doubt its practicability. I should think that it would have its greatest value in those cases in which there is difficulty in determining whether or not the patient has recovered. It should not be forgotten that approximately 15 per cent of the patients suffering from tularemia show a cross-agglutination reaction with the abortus organisms. Differentiation between the two conditions can be made, however, by agglutination absorption tests.

TREATMENT

Many attempts at specific treatment of this disease have been made. Favorable results have been reported for the intravenous use of mercurochrome,¹¹ metaphen¹² and acriflavine hydrochloride.¹³ Cazalas,¹⁴ Auric-

chio,¹⁵ Cumston,¹⁶ DeFinis,¹⁷ Giuffrè,¹⁸ Khaled,¹⁹ Prausnitz,²⁰ Schilling,²¹ Simpson⁹ and Harris²² have all reported favorable results with specific vaccine therapy.

Early in 1928 I became particularly interested in the use of vaccine and in 1929²³ I reported ten cases that were cured by this method of therapy. I early enlisted the cooperation of a large veterinary laboratory of the Middle West for securing pathogenic strains of *Brucella*. These cultures, after being thoroughly tested for virulence, were incorporated into a vaccine, 50 per cent *Brucella abortus* bovine and 50 per cent *Brucella abortus* swine being used. This was standardized to nephelometer number three, which is approximately six billion organisms per cubic centimeter. This particular preparation was submitted to the Council on Pharmacy and Chemistry in 1929, and in its report of 1930²⁴ acceptance was withheld until further clinical data were available. In 1932²⁵ it was fully accepted.

Arbitrarily 0.25 cc was chosen as the initial dose given intramuscularly. This dosage was increased 0.25 cc every second or third day, depending on the clinical reaction of the patient. A maximum dosage of 1 cc was never exceeded in the cases that I have treated. I found early that the subcutaneous method of inoculation was too frequently associated with local abscesses, I therefore changed to the intramuscular route of injection, which gives faster absorption and has been in my experience rarely so complicated. I have usually employed the deltoid muscle as the favored site for inoculation. I think it advisable that not more than seven inoculations should be given during a single course of therapy and that the dosage should not exceed 1 cc. The average number of inoculations in the 100 cases was 5.4.

In one case a spectacular result with intravenous vaccine was obtained. After treatment over a long period of time with subcutaneous injections of vaccine, without appreciable benefit, this patient was given one injection of 0.1 cc intravenously, resulting in a prompt cure. The reaction was so severe, however, that since then I have never used the vaccine intravenously. The reactions observed are specific and occur only in individuals who have been sensitized through actual infection with *Brucella*. If there is no elevation of temperature or no accentuation of the patient's symptoms during the course of vaccine therapy, the diagnosis should be carefully checked, for it is doubtful whether the patient has brucellosis. In control cases I have found the vaccine to be a very poor nonspecific protein. There is also an associated definite specific local reaction, characterized by soreness, induration and redness.

I believe that so long as the agglutinins persist in the blood stream, or the patient has active fever, this

fever can be accentuated by the use of vaccine. This is the result of an allergic systemic reaction. Consequently, fever can be prolonged unnecessarily by too long continued treatment. If the subjective symptoms of the patient have definitely subsided, injections of vaccine may be discontinued even in the presence of a low residual temperature. There follows a gradual disappearance of the clinical symptoms, including the fever. There is also a gradual return to a normal blood picture. I have had numerous letters stating that the vaccine yielded poor results and that as soon as its administration was stopped the patient got well. I feel that the continued fever in such cases is due to over-treatment.

There are certain contraindications to vaccine therapy. Particularly is the elderly individual a poor subject. His general physical condition is usually such that any form of "shock treatment" is contraindicated. A myocardium which shows the degenerative changes of senility makes that individual a particularly poor risk. I have also advised against the use of vaccine in two cases in which subacute bacterial endocarditis existed as a complication. In one of these cases injections of vaccine had been given prior to my observation and this had had no effect on the condition.

In cases in which satisfactory clinical results have not been obtained early in the course of vaccine therapy, a thorough investigation may reveal the presence of some complication, such as suppurative disease in the gallbladder, sinuses and tonsils. It has been pointed out by Harris²² that a thorough x-ray study of the teeth should be made for the existence of periapical infection.

During the course of active treatment with vaccine, the patients in this series received no other medication. They were usually kept under observation two or three days until a definite base line could be drawn as to their exact condition. In addition to vaccine therapy, all patients received a high caloric diet, with feedings between meals. This is very important in the handling of patients with prolonged fever. After the patient shows clinical signs of improvement, a tonic mixture particularly rich in vitamins was prescribed. A large number of such proprietary mixtures are on the market and I have no particular preference. Patients showing a blood picture of secondary anemia were given adequate amounts of iron, usually in the form of pills of ferrous carbonate, 45 grains (3 Gm.) daily.

RESULTS

The interpretation of the end results of any method of treatment applied to either acute or chronic brucellosis is difficult. The question often presents itself in a case in which there is apparent recovery "Is the patient well?" or "What are the criteria by which one can establish that the patient is cured?" In answer to these questions it may be stated that as the patient recovers from brucellosis

- 1 There is a definite disappearance of his subjective symptoms
- 2 There is an increase in weight
- 3 There is a gradual disappearance of fever
- 4 The agglutination titer of the blood diminishes
- 5 The blood picture returns to normal
- 6 The neurologic symptoms subside

In the 100 cases reported none are included that have been under observation less than one year. Two deaths have occurred from a complicating subacute bacterial endocarditis in which *Brucella* was shown to

be the etiologic organism. Short relapses have occurred in 11 per cent. These cases have required an additional course of vaccine therapy. One case remains unimproved after a period of one year, owing to a complicating chronic cholecystitis and also multiple periapical infections of the teeth. Five cases were recorded as quiescent at the time of my observation and no vaccine was recommended. Eighty-four cases were observed and treated in the hospital. The average hospital stay was twenty-two days. Readmission was necessary in eight cases for an additional course of vaccine therapy or treatment of known complications.

COMMENT

In view of the fact that all students of this disease have emphasized that there is a large number of cases unrecognized and untreated in the United States, I would urge that, in each laboratory where blood is taken for the Wassermann reaction, the rapid agglutination test be made on the same serums. Suitable antigen can be obtained from any veterinary supply company, and the test is performed by the addition of one drop of serum to a drop of antigen and, after mixing, a macroscopic agglutination occurs if the serum is positive. This test can be performed in any physician's office and offers a very practical and easy way of increasing the percentage of diagnosed cases in the United States. In 2,000 consecutive blood Wassermann serums observed at my laboratory, 26 per cent have shown positive agglutination with *Brucella*. Of course, some of these are quiescent cases. Sixteen of my active cases were recognized in this manner.

CONCLUSIONS

- 1 Brucellosis is on the increase in the United States
- 2 Vaccine therapy offers the best available method of treatment of both acute and chronic brucellosis
- 3 The rapid method of agglutination test should be done on all Wassermann serums
- 4 Brucellosis should be considered as a possible etiologic factor in many cases of so-called neurasthenia
- 5 *Brucella* may be found to be the etiologic organism in many so-called sterile abscesses, if proper investigation is made

1200 Huron Building

ABSTRACT OF DISCUSSION

DR HAROLD J HARRIS, Westport, N. Y. Within two and one-half years I have observed seventy-five cases of *Brucella* abortus infection. Only nineteen could be classified as acute, the remainder running a chronic course with little or no febrile reaction and never enough illness to require bed rest. One chronically ill woman aborted three times, from her uterine discharge *Brucella* abortus was isolated. Pallor is often striking, with or without anemia. Anemia may be profound. There is apt to be a marked tendency to alveolar abscess. One patient having had twenty-eight abscessed teeth. Too much confidence has been placed in the blood agglutination test for the diagnosis of undulant fever, acute or chronic. Physicians have been led to believe that an agglutination titer under 1:80 is of little or no clinical significance. No clinician familiar with undulant fever is misled by this idea. In eleven of my seventy-five cases of chronic undulant fever the agglutination test was entirely negative on repeated tests. These cases were diagnosed on positive skin tests and clinical evidence. Much harm has been done by the habit of laboratories of labeling as characteristic only agglutinations in 1:80 or higher dilutions. Regarding treatment, my experience coincides with that of Dr. Angle, vaccine having been the only method of proved value. A small percentage of my patients with chronic brucellosis treated a year or more ago, have suffered mild relapses in

spite of what I considered adequate vaccine therapy. It occurs to me now that these patients might not have relapsed if their antibodies had been maintained at a high level for longer periods of time. With this in mind, I am now watching their agglutination titers more carefully during their vaccine therapy and giving any dose necessary to secure and maintain a higher titer and, when necessary, I give small doses of the vaccine intravenously with apparently satisfactory results. Severe reactions may follow the use of this route, but extremely small doses may be used with safety in those whose agglutinins will not increase with the subcutaneous or intramuscular route. This route was used with success in a woman of 83 with marked weakness of the heart muscle. One dose of 50,000,000 killed organisms was given. It seems probable that undulant fever is a relapsing or recurrent disease only because the presence of large amounts of antibodies in the blood is so fleeting, therefore the problem is to keep antibodies present for a period sufficient to outlive the infecting organisms. I agree with Dr. Angle's statement that a patient who does not show the typical reaction to vaccine during treatment probably does not have brucellosis. I believe that the vaccine may be used as a therapeutic test with full assurance that the patient who is not suffering from brucellosis will not react in any degree.

LYMPHOCYTIC, MYELOCYTIC AND MONOCYTIC NEOPLASMS

ROENTGEN DIAGNOSIS AND TREATMENT

HOWARD P. DOUB, MD

AND

FRANK W. HARTMAN, MD

DETROIT

Since the establishment of the Lymphatic Tumor Registry by the American Association of Pathologists and Bacteriologists, eight years ago, much progress has been made in assembling, correlating and extending the knowledge of neoplastic conditions of lymphatic, hematopoietic and reticulo-endothelial tissues as evidenced by the recent publication of the registrar, Dr. G. R. Callender.¹ With these advances in the clinical, hematologic and pathologic aspects of this difficult group of neoplastic diseases there has been little attempt to collect and correlate the x-ray studies, although many reports of cases and groups of cases are found in the current literature.

This paper represents an attempt to gather and correlate some of these x-ray studies through a report of some of our own cases and the review of others from the literature furnishing typical examples in the various classifications discussed by Callender.¹ In a further effort to clarify the subject, the group of sympathetic neuroblastomas, which metastasize widely to lymph nodes, bones and bone marrow, are contrasted with the group under consideration. Callender's classification tracing the various diseases back to the stem cell of the lymphocyte, polymorphonuclear leukocyte and monocyte is used throughout.

LYMPHATIC LEUKEMIA

In lymphatic leukemia there is involvement of the lymph glands and structures throughout the body with an enormous increase in the lymphocytes. The lymph gland involvement is usually generalized and in many instances the liver and spleen are enlarged. In the

lymph nodes there is a great proliferation of the lymphocytes so that there is obliteration of the node structure. The malpighian nodules of the spleen become enlarged to a considerable degree. The bone marrow may become more or less transformed into lymphoid tissue. Profound anemia usually is present from replacement of the normal bone marrow.

Roentgen examination is indicated in all cases of pain or swelling over the bones and joints. Craver and Copeland² report bone changes in six of eighty-six cases of lymphatic leukemia. They feel that bone changes are of more frequent occurrence in low grade lymphatic leukemia than in cases with a high white count. The incidence of bone changes was, in order of frequency, femur, humerus, pelvis, metacarpals, ulna and vertebrae.

There may be elevation of the periosteum due to infiltration beneath the periosteum, and this is sometimes followed by osteosclerosis from proliferation of new bone. Extensive generalized osteoporosis may sometimes be present without localized areas of destruction. Snelling and Brown³ report bone changes at some stage of disease in eight of twelve children with lymphatic leukemia. Their most constant change was a rarefied area near the end of the bone adjacent to the epiphyseal line together with elevation of the periosteum. Poynton and Lightwood⁴ and Taylor⁵ report extensive periosteal changes in these cases. The former report elongated localized leukemic deposits in the ends of the bones, with absorption of the bony cortex about these deposits.

Occasionally in this disease masses are found in other organs, such as the gastro-intestinal tract. Mead⁶ has recently reported a case with tumor masses throughout the stomach almost like diffuse polyposis, also masses in the small bowel and colon.

Mediastinal tumors in connection with lymphatic leukemia have frequently been reported. This has been called leukosarcoma by Sternberg,⁷ who thought it was a true neoplastic tumor. Other authors believe it to be a part of the general leukemic process. Cooke⁸ has reported nine cases of acute leukemia with large mediastinal masses. In these cases roentgen therapy promptly removed the masses, but in a short time the blood changes returned acutely. After this the roentgen therapy was of no avail and the patients died.

A number of cases of lymphatic leukemia associated with lymphosarcoma have been reported. These cases apparently begin as lymphosarcoma and later develop leukemic manifestations, often of the acute type. Evans and Leucutia⁹ reported three cases of lymphosarcoma, which were treated by roentgen therapy with marked improvement. The patients later developed lymphatic leukemia and died. The authors believe that lymphosarcoma is transformed into lymphatic leukemia as soon as the bone marrow becomes involved by foci of lymphosarcoma.

From the Departments of Roentgenology and Pathology, Henry Ford Hospital.

CASE 1—L. P., 37 years, aged 35, admitted, Feb 23, 1935, complained of weakness and substernal pain. The onset had occurred with insomnia and "cold in the chest," and cough but no sputum or hemoptysis. There was progressive weakness and dyspnea on exertion. Substernal pain developed, with coughing.

On physical examination the left side of the chest was more voluminous than the right, with restriction of movement on the left. There was impaired percussion with absent breath sounds on the left below the angle of the scapula. The abdomen was distended. The spleen was not felt. No lymph gland enlargement was present.

Laboratory examinations revealed the following. The Wassermann reaction was negative. Blood studies showed hemoglobin, 82 per cent, red blood cells, 4,900,000, white blood cells, 9,200, differential count polymorphonuclear neutrophils, 66 per cent, polymorphonuclear eosinophils, 8 per cent, metamyelocytes, 2 per cent, lymphocytes, 22 per cent, monocytes, 2 per cent.

Roentgen examination of the chest revealed a large collection of fluid in the left pleural cavity, with displacement of the mediastinum. After 1,200 cc of fluid was removed, progress films showed widening of the mediastinum.

High voltage roentgen therapy was administered over the mediastinum and lumbar area, which resulted in disappearance of the mediastinal mass. Some fluid continued to form in the left pleural cavity. The patient improved and went home, March 16, but was readmitted several days later with exacerbation of the coughing, oozing of blood from the gums, paralysis of the left side of the face, and palpable glands in the cervical, axillary and inguinal areas.

Examination of the blood showed red blood cells, 5,120,000, white blood cells, 101,000, hemoglobin, 80 per cent, polymorphonuclear neutrophils, 8 per cent, lymphocytes, 12 per cent, blast forms 80 per cent. On succeeding days the white count increased steadily to 253,000, and slowly fell to 6,200 and then rose to 18,400 over a period of two weeks. The stools showed a positive guaiac test. During all this time the patient was treated with repeated blood transfusions.

A postauricular lymph node was removed for study. The normal follicular structure was entirely replaced by masses of lymphocytic type cells with abundant mitotic figures.

The patient continued to grow worse and died April 7. He suffered a pulmonary hemorrhage as a terminal event.

At necropsy the spleen and liver were somewhat enlarged. Multiple small discrete petechial hemorrhages were found both in the skin and in many of the internal organs. There was an area of hemorrhagic pneumonia involving the upper lobe of the right lung. The spleen showed replacement of the lymphoid follicles by masses of small, deeply staining lymphocytes. The kidneys contained areas of lymphocytic infiltration. There was infiltration of the mediastinal, mesenteric, retroperitoneal and inguinal lymph nodes. Sections of blue marrow were taken from the lumbar vertebrae, sternum and ribs. The marrow was hypertrophic, with enlargement of the marrow cavity and of the cortex. There was considerable replacement of the normal medullary elements by small deeply staining lymphocytes. The changes were indicative of acute lymphatic leukemia.

This would appear to be a case of lymphosarcoma which after roentgen therapy developed an acute lymphatic leukemia. It is difficult, however, to be sure that this was not a case of lymphatic leukemia in an aleukemic stage when first seen and which passed into the leukemic stage after roentgen therapy. Webster¹⁰ reported a case (case 3) which was very similar in its history and pathologic manifestations to those of case 1 reported here. He places it in the leukosarcoma group. He believes it probable that leukosarcoma, lymphosarcoma and lymphatic leukemia are different manifestations of the same disease.

The prognosis in lymphatic leukemia is uniformly bad but, in the chronic type, roentgen therapy may

prolong life for a considerable period of time. The acute form is a rapidly progressive form of the disease resulting in death in from a few days to a few weeks. We believe that roentgen therapy is not indicated in these cases and may even hasten the time of death. The chronic cases are more amenable to roentgen therapy and these patients survive for from a few months to four or five years. We do not consider that roentgen therapy is as effective in lymphatic leukemia as it is in myelogenous leukemia.

MYELOGENOUS LEUKEMIA

There is a definite elevation of the white blood cells with a large proportion of myelocytes. Both the total count and the differential count are capable of wide variation. Extensive changes are found in the bone marrow with hyperplasia of the granular leukocytic elements and decrease of the red marrow. Myeloid transformation is present in the spleen and liver particularly and may occasionally be seen in other organs. Bone destruction is uncommon.

Cone¹¹ states that myelogenous leukemia resembles sarcoma in a fluid medium. He believes that the clinical and pathologic manifestations indicate it to be of a sarcomatous nature. Piney¹² also believes it to be a neoplastic process and to be more rapid in its course when composed of immature cells.

Roentgen examination of the bones reveals very few changes. Craver and Copeland² in a report of eighty-two cases found bone changes in only one case. There was mottling of the upper portions of the femurs, with central punched-out lesions. There may also be osteosclerosis. Early lesions may be missed by roentgen examination. At autopsy they found various stages of absorption of the spongy trabeculae and some erosion of the cortex. Erosions of medullary bone were found in stages that could not be demonstrated roentgenologically. These authors conclude, therefore, that changes shown by the roentgen examinations are late changes.

Roentgen therapy is, and has been for many years, the chief therapeutic agent for the control of this disease. In spite of brilliant temporary remissions, the course of the disease proceeds uniformly to a fatal termination. Irradiation is usually applied over the long bones, vertebrae, ribs and sternum in order to destroy the radiosensitive myeloid hyperplasia. Irradiation of the spleen is also indicated for reduction of its size and destruction of the pathologic blood cells. In certain instances in which it is enlarged by leukemic infiltration, the liver also should be treated. After each recurrence the response to irradiation is less than formerly, and finally a stage arrives in which all treatment is ineffectual.

CHLOROMA

Chloroma, or chloroleukemia, may be said to be a tumor-like hyperplasia of the parent cells of the leukocytes, primary in the bone marrow. It is more common in young males but cases in the fifth and sixth decades have been reported. Dock and Warthin¹³ in 1904 definitely established the relationship of chloroma and leukemia. Some writers divide the disease into myeloid and lymphoid groups, but the consensus at present is that the lymphoid group is extremely rare or non-existent. Swanson¹⁴ and others have reported cases

10 Webster L. T. Lymphosarcoma and Allied Conditions. Johns Hopkins Hosp. Rep. 20: 251-314, 1921.

showing an aleukemic form of the disease. Some writers, however, state that these are only aleukemic stages and not aleukemic types of the disease.

Postmortem examinations have usually revealed widespread, green colored growths with a marked predilection for the periosteum, the dura and the ligamentous structures. Involvement of the cranial bones, ribs, sternum and long bones is frequently found. The bone marrow often has a greenish cast. Exophthalmos with hemorrhage into the eyelids is a characteristic picture and is usually caused by retrobulbar masses of leukoblastic tissue. Pleural involvement with effusion is common. The cells are large, undifferentiated, mononuclear cells designated as myeloblasts or large lymphocytes. A moderate degree of anemia is usually present.

Roentgen changes in chloroma are quite variable. In some reported cases rather marked destruction was seen in the long bones and occasionally bone proliferation was present. In one case there was a large area of destruction in the vault of the skull underlying a soft tissue tumor. Extensive periosteal changes are usually present over the long bones. This periosteal change may consist of elevation of the periosteum parallel to the shaft of the bone, or there may be striae perpendicular to the bone similar to the changes seen in osteogenic sarcoma. The bone changes are often seen near the ends of the diaphyses of the long bones. In some cases, widening of the mediastinum was present.

Washburn¹⁵ reported a case of chloroma in a boy, aged 20 months, who was given roentgen therapy. This resulted in an apparent complete recovery. The child was still living and well at the time of the report two and one-half years after the administration of roentgen therapy. In case 2 we administered high voltage roentgen therapy, which lowered the white blood count but had little appreciable effect on the progressive course of the disease.

CASE 2—M. F. DeC., a white youth, aged 17, admitted, March 19, 1931, complained of swollen, stiff joints and lumps on the head. The condition had begun seven weeks before with gradual swelling of the ankle joints and pain on motion. The joints were warm but not hot or red and not sore to the touch. Later the knees, then the elbows became involved. Three weeks later the mandibular joints became involved so that the mouth could not be closed. At that time several teeth were extracted, with rather copious hemorrhage following the extraction. During the fourth week of illness, tumors developed over the head, which gradually enlarged. The eyes had been protruding for the past ten days, and there was marked edema of the lids. Loss of weight amounted to 25 pounds (11.3 Kg.) in seven weeks.

The history was otherwise negative, with the exception of an attack of rheumatism three years before.

On physical examination the patient presented a striking appearance, with marked exophthalmos and edema of the upper lids, and the presence of large, nodular, circumscribed, hard masses distributed over the skull, particularly in the parietal and occipital areas on both sides. There was a softer swelling over the zygomatic area, which increased the breadth of the face. The eyeballs were definitely protruded. Some nasal obstruction was present. The mouth was wedge shaped and there was swelling over the temporomandibular articulations and the maxilla.

There was general lymphatic adenopathy. The liver and spleen were easily palpable. There was a globular enlargement over the lower end of the left humerus.

The physical examination was not of interest otherwise, except for a few vague changes in the chest. The blood pressure was 130 systolic 50 diastolic.

Laboratory examinations showed red blood cells, 3,350,000, hemoglobin, 48 per cent, white blood cells, 24,200, polymorphonuclears, 4 per cent, small lymphocytes, 7 per cent, large mononuclear leukocytes, 4 per cent, myeloblasts, 83 per cent. The myeloblasts varied from 8 to 20 microns in diameter. The nucleus was unusually large, the cytoplasm being represented by a rim of darker staining granular material. The nucleus stained lightly with Wright's stain and often appeared polymorphous or definitely lobulated. With the oxydase stain, the majority of the myeloblasts showed blue-staining granules in the cytoplasm.

The Wassermann reaction was negative. The phenolsulphonphthalein test showed a return of 27 per cent in two hours.

Roentgen examination disclosed the following changes. In the skull there were multiple pinhead sized radiolucent areas through the vault, and an irregular fuzzy type of decalcification of the facial bones. There was a collection of fluid in the right pleural cavity. The right lung showed extensive infiltration. Practically all the bones showed evidence of an infiltrative lesion with an osteoporosis having a granular appearance. There were areas of bone destruction in the shafts of the humeri near the upper epiphyseal lines. Periosteal reaction was seen over many of the long bones. Around the left elbow there were raylike striae perpendicular to the bone, and similar but less marked changes were seen around the knees. We felt that the whole picture was that of a blood dyscrasia of an undetermined type.

The patient's general condition continued to decline in spite of blood transfusions and general medical care. The temperature ranged from 99.5 to 103 F.

The blood calcium was 11.5 and the blood sugar 91 mg per hundred cubic centimeters. The urine was negative for Bence Jones bodies.

A gland was removed for examination. It was definitely green. Microscopically it showed loss of the normal lymph gland architecture. The tissue was composed of cells of the myelogenous type, which were usually large and had pink staining and round or oval bilobed and polymorphous nuclei. Mitosis was quite marked. A diagnosis of chloroma was made.

March 31, roentgen therapy was started and one-half erythema dose was given over the head, cervical areas, shoulders, elbows, inguinal areas and one area over the spleen, 0.5 mm. of copper plus 1 mm. of aluminum filtration with 185 kilovolts at 50 cm. distance was used.

During this treatment period the patient's general condition improved to a marked degree, and on the last day of treatment the white blood count was 20,500. Two days later the count dropped rapidly and declined to as low as 1,500, but under repeated small transfusions gradually came up to 2,800. At this time an area of gangrene developed with ulceration at the gingivobuccal fold of the left lower mandible. This progressed in spite of medical care and eventually sloughed through the cheek.

The patient seemed to improve temporarily and the fluid in the chest cleared up. After a short time the condition became worse and the patient died one month after the high voltage roentgen therapy. At that time the white count was 24,500. Autopsy was not permitted.

It is apparent that this was a tumor closely connected with leukemia and may be properly considered as a subvariety or form of myelogenous leukemia. Practically all the well studied cases reported during the past twenty years have been of myelogenous origin.

These cases, in addition to the blood picture, are characterized by green tumors in almost every part of the body and in many cases they cause exophthalmos by tumors behind the eyeballs. Bone involvement and periosteal reaction, sometimes perpendicular to the bone as in osteogenic sarcoma, are found on roentgenographic examination. General glandular enlargement is found, together with enlargement of the spleen and liver.

Practically all cases reported in the literature ended fatally, with the exception of one patient who was living

15 Washburn, A. H. Chloroma. Report of a Case with Recovery Following Roentgenotherapy. *Am. J. Dis. Child.* 39: 330-343 (Feb) 1930.

and well two and one-half years following roentgen therapy. Case 2 showed some improvement with clearing up of the pleural effusion, following roentgen therapy.

ALEUKEMIC MYELOSIS

There are certain atypical cases of generalized myeloid hyperplasia of the bone marrow and viscera in which the white blood count and differential count are practically normal. If immature forms are present in the blood stream, they occur at such irregular intervals or in such low numbers that they are of no diagnostic value. There is usually a definite anemia present. Aleukemic and leukemic myelosis are in many instances indistinguishable by histologic examination.

Baldrige and Fowler¹⁶ state that 5 per cent of their patients with diffuse myelosis were permanently aleukemic. They believe that the aleukemic form of myelosis may be more rapidly fatal and may have a greater degree of associated anemia and more likelihood of secondary hemorrhagic purpura than the leukemic form. Splenomegaly is a striking clinical finding.

The roentgen changes are of considerable importance in the differential diagnosis. The bone changes may be either osteolytic or osteosclerotic. The osteolytic type may easily be mistaken for multiple myeloma, as in case 3, or it may suggest metastatic carcinoma. Baldrige and Fowler's¹⁶ case 4 showed only a single area of osteolysis in the mandible. In their case 5 there were multiple areas of bone absorption together with subperiosteal proliferation parallel to the shaft of the bone. There were also perpendicular striae found near the muscle and tendon attachments of numerous bones. In the spine, the lesions were osteoblastic in type. In the cranial bones there were multiple pinpoint areas of decalcification. Their case 6 showed evidence of rarefaction round the distal ends of the long bones, with a generalized osteoporosis. Stephens and Bredeck¹⁷ reported two cases presenting generalized osteosclerosis which were indistinguishable from metastatic carcinoma of the osteoblastic type.

Therapy in this group of cases is of no avail. Jaffe¹⁸ quotes various authors to the effect that splenectomy always seems to be fatal, the patients dying during the operation or soon after. He also states that irradiation of the spleen seems to be of no avail. In one case reported by Baldrige and Fowler¹⁶ irradiation was applied to a nodule on the forearm with about 75 per cent reduction in size in seventy-two hours.

CASE 3.—A B, a white woman, aged 51, admitted Aug. 28, 1934, complained of pain in the back, loss of weight, and weakness.

The patient's father died of a tumor at the age of 40. Her past history was negative in relation to her present illness.

She dated the pain from September 1933 while watching boat races. This grew worse in a month and spread all over the spine and to the shoulders and neck. The pain did not seem any worse than at the beginning of her illness. She had lost 44 pounds (20 kg.) since October 1933. There had been progressive weakness since the onset of symptoms.

The patient was moderately emaciated and quite pale. The chest was barrel shaped and somewhat deformed, as if from previous rickets. The heart was slightly enlarged. No abdominal masses could be palpated. There were a few palpable glands in the cervical and inguinal areas. Limitation of motion

of the shoulders was present. There was exaggeration of the dorsal kyphosis. Marked weakness prevented the patient from standing.

Laboratory examination revealed Wassermann reaction, negative, red blood cells, 3,120,000, white blood cells, 13,100, polymorphonuclear neutrophils, 73 per cent, polymorphonuclear eosinophils, 1 per cent, small lymphocytes, 21 per cent, large lymphocytes, 2 per cent, transitionals, 3 per cent, hemoglobin, 94 Gm. Moderate poikilocytosis was present. The blood calcium was 13.67 mg. and phosphatase, 4.55 mg.

Roentgen examination showed marked osteoporosis of the cervical vertebrae and osteoporosis, with narrowing of several of the dorsal and lumbar vertebrae. The ribs and scapulae also showed osteoporosis, with areas of destruction throughout these bones. Similar changes were seen in the pelvis and femurs. The skull was the seat of multiple areas of destruction scattered throughout the cranial vault. These areas varied in size from a few millimeters to 2 cm. The impression was that this case was probably one of multiple myeloma.

The patient steadily declined and died, September 18.

At autopsy, in each kidney a tumor mass was found. These were rubbery in consistency and suggested an infiltrative mass, since the margins were not sharply delimited. A few enlarged retroperitoneal glands were found and on section resembled the kidney lesions. In the bodies of the lower dorsal and lumbar vertebrae the bone marrow was replaced by grayish, friable, granular material suggesting leukemic involvement. There was marked decalcification of all the bones. The essential bone lesion appeared to be a rarefaction of bone structure with thinning of the cortex together with replacement of these structures by grayish, friable, very cellular tissue.

Microscopic examination of the lymph nodes showed the normal lymphatic structure almost entirely replaced by cells derived from the granulocytic elements. There were myelocytes and myeloblasts and polymorphonuclear leukocytes. There were also large multinucleated giant cells which resembled megakaryocytes. The remaining cells were lymphocytic and monocytic in nature. Similar cellular elements were observed in the kidney lesions. The material from the bone marrow was made up of closely packed masses of myelocytic cells with stroma. These included not only myelocytes but also myeloblasts and partially obscured polymorphonuclear leukocytes together with occasional large, multinucleated pink-staining megakaryocytes. An occasional erythroblast was seen. A diagnosis was made of diffuse aleukemic myelosis involving the vertebrae, ribs, sternum, kidneys, spleen, retroperitoneal lymph nodes and liver.

HODGKIN'S DISEASE

Hodgkin's disease is characterized by painless progressive lymph node enlargement, often beginning in the cervical groups. It is frequently accompanied by fever, and in later stages by anemia and cachexia. The blood changes are not diagnostic, although there is usually a slight leukocytosis as the disease progresses. There may be an increase in the eosinophils and lymphocytes. The blood platelets are usually increased.

The glandular involvement may be local or it may involve all the lymph glands of the body. The spleen is frequently involved and enlarged. The liver is less often affected. Cutaneous manifestations are common and quite annoying, because of pruritus.

The bone marrow may be involved rather frequently. Krumbhaar¹⁹ has reported a case with involvement of the bone marrow and spleen without involvement of the lymph nodes. Craver and Copeland²⁰ reported twenty-seven cases of demonstrable bone changes (15.7 per cent) in a series of 172 proved cases of Hodgkin's disease. They report the incidence of osseous changes from other authors' reports as varying from 10.7 per

²⁰ Craver L. F. and Copeland M. M. Changes in the Bones in Hodgkin's Cranioma. Arch. Surg. 28: 1062-1086 (June) 1934.

cent to 34 per cent. Pain usually preceded discovery of the bone lesions, although in some cases the lesions were discovered accidentally by roentgen examination. In a review of the literature they found the following bones involved in the order of their frequency: vertebrae, sternum, pelvis, femur, ribs, skull, humerus, scapula and clavicle.

Roentgen examination discloses both osteoclastic and osteoplastic lesions. In the spine the two types of lesions may be present in the same case. When osteoclastic lesions are present there may be collapse of the affected vertebrae, with considerable deformity. In one of our cases the collapse occurred when the patient was sitting up in bed. The disks are usually unaffected. The pelvis may show rather extensive osteolytic lesions with large, cystic-like areas interspersed with areas of eburnation. Pfahler and O'Boyle²¹ reported a case of sacro-iliac involvement, which cleared up under roentgen therapy. We have recently had a patient with similar involvement, which cleared up similarly under roentgen therapy.

Lesions of the long bones are apt to begin in the proximal ends. In some instances the lesions are exactly similar to metastatic malignant growths of the osteolytic type, while in others there is evidence of sclerosis surrounding faintly visible areas of bone destruction. There may be some periosteal thickening. The ribs show similar punched-out areas of bone destruction. Lesions of the skull are apt to be osteoclastic.

Roentgen therapy is the most effective agent in the treatment of Hodgkin's disease. Radium therapy may be used but is not economical as to time or expense, and the final results are practically the same. The method of applying the radiation therapy varies as to dosage applied, voltage and filtration, also as to the number of areas treated. Desjardins²² prefers the use of from 135 to 140 kilovolts filtered through 4 to 6 mm of aluminum. He also advocates treating all the bodily lymph nodes even though only part of them have demonstrable involvement. Leucutia²³ uses voltages from 160 to 200 kilovolts filtered through copper or zinc and exposes only the actually diseased areas. Craver and Copeland²⁰ advocate high voltage applied in either suberythema or fractional doses, depending on the local and general condition of the patient. We use from 180 to 200 kilovolts filtered through 0.5 mm of copper applied in suberythema doses when the patient is in satisfactory condition, otherwise, fractional dosage is used. We treat only the areas of demonstrable involvement because we consider that the disease has a hopeless prognosis, and excessive irradiation may cause leukopenia and severe anemia in a patient who is in need of all his bodily defenses. Craver and Copeland²⁰ have aptly stated the case: "The treatment regarded as best is that which will secure the best palliation for the longest time. The treatment should never be so severe as to make it seem harder to bear than the disease." Leucutia²³ states that the five year survival group mounted to from 15 per cent to 33 per cent. In 8 per cent of the cases there is a ten year survival. In addition there is considerable symptomatic improvement.

²³ Leucutia, Traian. Irradiation in Lymphosarcoma, Hodgkin's Disease and Leukemia, *Am J M. Sc.* 188: 612-623 (Nov.) 1934.

CASE 4—F. C., a white man, aged 40, admitted, Nov. 17, 1934, complained of swelling of the neck and low back pain. Examination revealed a large mass of glands in the right cervical area. There was also enlargement of the axillary and inguinal glands. Some tenderness was elicited over the lower part of the back. The blood studies were negative. Biopsy of an axillary gland resulted in a diagnosis of Hodgkin's disease. Roentgen films of the chest showed widening of the upper mediastinum.

High voltage roentgen therapy was administered over the cervical, inguinal, axillary and mediastinal glands and also over the lumbar spine. From 190 to 200 kilovolts was used and from 560 to 696 roentgens per field was administered. This resulted in disappearance of the glands in one month, but the patient continued to feel bad.

May 13, 1935 he was readmitted. On examination a few superficial glands were felt. There was a large mass in the upper part of the abdomen apparently continuous with the liver and extending below the umbilicus on the right side. The spleen was not felt. Roentgen examination at that time revealed fluid in the right pleural cavity. There were punched out areas of bone destruction in the right scapula and several ribs. There was also involvement of the dorsal and lumbar vertebrae, with areas of destruction, and extensive decalcification of many of the vertebrae. There was also extensive involvement of the bones of the pelvis and upper portion of the right femur.

May 21, when the patient sat up in bed, he had a feeling that his spine gave way and marked tenderness was elicited over the midlumbar area. Roentgen examination showed definite narrowing of the seventh dorsal vertebra.

LYMPHOSARCOMA

Lymphosarcoma is similar in many of its clinical aspects to Hodgkin's disease and it may be difficult to separate the two. It often involves a somewhat older group in general. There is less likelihood of an accompanying fever, and it is more radiosensitive than Hodgkin's disease. Lymphosarcoma frequently involves parts of the gastro-intestinal tract and peritoneum. Microscopic examination of an excised gland is necessary to establish the exact diagnosis.

Bone involvement in lymphosarcoma is not nearly so common as it is in Hodgkin's disease. The roentgen changes are similar, however. There are sometimes osteolytic lesions of the long bones with pathologic fracture. Occasionally periosteal lesions are seen. Pohle and Ritchie²⁴ reported a case of lymphosarcoma of the femur in which a pathologic fracture was sustained. There were areas of involvement in the left femur, right ilium, right radius, right parietal bone and several ribs. There were areas of increased bone density as well as areas of osteolysis. At autopsy widespread lesions were found. In the ribs there were fusiform osteolytic lesions with pathologic fractures. Microscopically it proved to be lymphosarcoma. Leucutia²³ found the cortex intact in his cases, except for occasional areas of invasion. He believes that this respect for the cortex by lymphosarcoma explains the rarity of roentgen changes in the bones. Histologically he found replacement of the bone marrow by tumor tissue and later gradual destruction of the normal bone marrow tissue.

In this disease roentgen therapy is also of prime importance. While lymphosarcoma almost universally causes the death of the patient, there are a few patients who have lived for a period of over ten years and who should probably be put in the category of cured cases. The average length of life in treated patients varies from two to four years. Approximately from

²⁴ Pohle E. A. and Ritchie G. Lymphosarcoma of the Femur, *Radiology* 18: 635-637 (March) 1932.

15 to 20 per cent will live five years. The reticulum cell type of lymphosarcoma is somewhat more resistant to radiation than the lymphocytic type, and the results show a shorter span of life. We prefer the use of from 180 to 200 kilovolts filtered through 0.5 mm of copper plus 1 mm of aluminum, and the administration of suberythema doses to the affected glands. We do not treat the areas in which involvement was not demonstrated, except in certain cases in which we have reason to believe that there may be involvement of the retroperitoneal nodes. In the abdomen, definite verification may be difficult to obtain unless the glands are quite large. The usual medical supportive measures should also be carried out in all these cases.

MONOCYTIC LEUKEMIA

Monocytic leukemia is a third type of leukemia about which there is no very general agreement as to its separate entity. It is characterized by an increase in the number of monocytic cells associated with extensive growth of the reticulo-endothelial cells in the various tissues. Most of the cases have been of an acute type lasting from a few weeks to several months. Pronounced anemias and some fever are usually present. There is elevation of the white blood cell count, with from 50 to 75 per cent of the cells being monocytes.

Postmortem studies show enlargement of the liver, spleen and lymph nodes. There is often involvement of the kidneys, adrenals and other viscera. In some reported cases tumor masses have been found similar to those in chloroma. The bone marrow is usually hyperplastic and there are groups of monocytes present which are not seen under normal conditions.

Very little information can be gained from the literature in regard to possible roentgen changes in the bones. Osgood and Lyght²⁵ have reported two cases in which roentgenograms were made of several bones but nothing suggestive was found. Doan and Wiseman²⁶ also found no roentgen evidence of pathologic changes of the bone in one of their cases. The same authors tried roentgen therapy in several of their cases with very little beneficial effect. Dameshek²⁷ also tried irradiation in a case without any considerable benefit.

COMMENT

In reviewing the roentgen changes in the bones of these cases, one cannot help but be struck by certain points of similarity in the various diseases.

Periosteal changes are of two types: (1) elevation of the periosteum with calcification parallel to the shaft of the bone, and (2) raylike striae perpendicular to the bone. In the diseases under consideration we find the parallel type of periosteal change in lymphatic leukemia, aleukemic myelosis, chloroma and Hodgkin's disease. In myelogenous leukemia and lymphosarcoma no similar changes were reported, but there are very few reported cases in the literature, so that it is possible that they might show this change. In the second type with perpendicular striae, these changes were found in chloroma and aleukemic myelosis. This was quite a striking finding in our case of chloroma and was very similar to the raylike changes that are seen in osteogenic sarcoma.

Bone destruction may be classified under several headings: 1. Punched-out areas of bone destruction. This type of lesion was present in myelogenous leukemia, aleukemic myelosis, chloroma, Hodgkin's disease and lymphosarcoma. 2. Bone erosion in the ends of the diaphyses of the long bones. This was found in lymphatic leukemia, aleukemic myelosis, chloroma and Hodgkin's disease. 3. Pinpoint areas of decalcification or destruction. These were seen in aleukemic myelosis and chloroma and were usually in the flat bones, particularly in the skull. 4. Erosion of the cortex from within the medullary canal. This was reported from pathologic material of myelogenous leukemia by Craver and Copeland,² who believed that it was rather difficult to demonstrate on the roentgenogram and considered it a late lesion.

Osteosclerosis was also a prominent finding in these diseases. It may be a generalized condition, as is seen in aleukemic myelosis, or may be present in certain locations, as is seen in Hodgkin's disease and myelogenous leukemia. It is seen occasionally in lymphatic leukemia.

Generalized osteoporosis has been seen in lymphatic leukemia, aleukemic myelosis, and chloroma. In some cases of long standing this might be atrophy from disuse, but there would also appear to be some cases presenting this sign due to the disease itself.

From this summary of bone changes it would seem that there are no characteristic changes that would lead one to differentiate these rather uncommon diseases roentgenologically. We have found, however, that the periosteal changes in conjunction with the peculiar moth-eaten areas of erosion at the ends of the diaphyses—usually at the proximal ends along the medial border—are changes that are rather uncommon in other diseases. When these are associated with the pinpoint areas of decalcification in the flat bones, one should suspect some myeloid or lymphoid neoplastic condition.

We have recently studied three cases of sympathetic neuroblastoma that show practically the same roentgen changes as the diseases under consideration. There were extensive areas of destruction in the long bones and areas of erosion at the proximal ends of the diaphyses. Considerable localized osteoporosis was present near the ends of the long bones at the knee joints in one case. Pinpoint decalcification in the skull was present, together with larger focal areas of destruction in the pelvic bones, ribs and scapulae. It would be very difficult from the roentgen picture alone to differentiate these cases from the neoplastic diseases. These cases will be reported in detail elsewhere.

In the differential diagnosis one must consider metastatic carcinoma, multiple myeloma, osteogenic sarcoma, xanthomatosis, Gaucher's disease, Albers-Schönberg's disease, and bone infections.

Therapy in these conditions is mostly concerned with irradiation, although the usual medical supportive measures are indispensable. In the acute form of lymphatic leukemia, irradiation is contraindicated and may even be harmful. In the chronic form startling remissions occur, but the prognosis is uniformly bad. The same may be said of myelogenous leukemia, although the span of life is somewhat longer and the morbidity is usually less. In aleukemic myelosis there is no treatment that gives even temporary satisfactory results, although this may be due to the fact that very few cases are diagnosed ante mortem and, therefore, no large statistics on therapy are available. One patient with chloroma

²⁵ Osgood, C. W. and Lyght, C. E. Monocytic Leukemia. *J. Lab. & Clin. Med.* 18: 612-626 (March) 1933.
²⁶ Doan, C. A. and Wiseman, B. K. The Monocytic Monocytosis and Monocytic Leukemia. *A Clinical and Pathological Study.* *Ann. Int. Med.* 8: 383-416 (Oct.) 1934.
²⁷ Dameshek, William. Acute Monocytic Leukemia. *Arch. Int. Med.* 40: 18-240 (Oct.) 1930.

was alive and well two and one-half years after radiation therapy, but no other case could be found in which the progress of the disease was arrested by any method of treatment. High voltage roentgen therapy is the method of choice in both Hodgkin's disease and lymphosarcoma. A considerable symptomatic improvement and temporary abeyance of the disease process is achieved in many cases by this method of therapy. The average length of life in these cases is definitely raised and in a very few cases one may use the term cure.

PROGRESS AND PROBLEMS IN ENDOCRINOLOGY

R. G. HOSKINS, PH.D., M.D.

Director of Research, the Memorial Foundation for Neuro-Endocrine
Research, Harvard Medical School
BOSTON

So rapid has been the progress in endocrinology during the past few years that selection of material for special consideration presents a difficult task. Hundreds of sound studies have been carried out and of these perhaps not one is without significance to pediatricians. Some, however, are of more immediate interest than others.

IMPORTANCE OF THE THYROID GLAND

Despite the wealth of new information about other glands, the thyroid gland still remains the most important to the practitioner in that thyroid problems are most easily recognized and the thyroid hormone is the most readily available and most effective for therapeutic purposes. The thyroid gland exercises a twofold function. In childhood it has a widely pervasive influence on the anabolic processes. Neither growth nor differentiation can take place in any adequate degree without the agency of the thyroid hormone. Thus, in thyroid deficiency there are seen all the well known abnormalities of physical and mental development and, as a result, poverty of the personality.

In the franker manifestations these effects are unmistakable and need no further elucidation. Thyroid deficiency, however, is manifested in all degrees from outspoken myxedema to complete normality. It is important to remember, as Shelton says, that "if physicians depend upon myxedema as the essential feature in the diagnosis of thyroid insufficiency at any period of life, then they must overlook the majority of hypothyroid sufferers."

There are a large number of cases of thyroid deficiency in children in which the gross signs of the condition, such as myxedema, dwarfism or obesity, are not apparent. Typically, the picture consists of moderate or slight delay in growth, teething and skeletal development, mental retardation, dry and brittle hair, poor nutrition and sluggish functions of the skin, constipation, emotional instability, disturbed sleep, capricious appetite and intractability, painful muscles and joints, and, what is especially illuminating, failure to respond to dietary treatment. An important cause of anemia that is rather commonly overlooked is thyroid deficiency. Frequently accompanying this are weakness and weariness. Menorrhagia and metrorrhagia in girls are not infrequently to be ascribed to this same cause. Several of the dermatoses can at

times be traced back to thyroid hypofunction. Lesser degrees of nervous involvement are seen as forgetfulness, inattentiveness and restricted initiative. Lissner is authority for the statement that thyroid deficiency also with significant frequency plays a causal role in certain diathetic manifestations in infants, including vomiting, intestinal colic and even megacolon and ascites. In short, neglect to consider this gland leaves many a pediatric problem only partially, if at all, solved.

The simultaneous occurrence of any two or three of the manifestations just listed should throw suspicion on the thyroid gland. The most direct aid toward the recognition of the glandular agency in the symptomatology is a study of carpal development as disclosed in roentgenograms. An elevation of the blood cholesterol content is also of some diagnostic significance, but so wide is the normal fluctuation of the titer that no great dependence can be placed on it. Often a therapeutic test with desiccated thyroid in small doses gives illuminating results. Variations in the creatine output are also worthy of further study for their diagnostic significance.

Little need be said at this juncture of the catabolic effects of the thyroid hormone. Occasionally these are seen in clinical manifestation in the early years, as in cases of exophthalmic goiter, and therapeutically this property is occasionally of use in the treatment of obesity. The stimulating properties of the thyroid hormone can be utilized further in case of a variety of deficiencies involving other endocrine glands. There is direct evidence that some of these glands are susceptible of stimulation by this agent, and there is presumptive evidence that this is true also of others. Despite the well grounded objections to glandular polypharmacy there is a sound basis for the addition of thyroid substance to a variety of other glandular products when it is desired to use not only substitution therapy but also supplementary glandular stimulation.

Perhaps an apology should be offered for reiterating these matters, as they have often been discussed in the medical literature. Nevertheless many physicians are disinclined to profit by them because of an exaggerated fear of thyroid medication. Despite the fact that the best way to place an endocrine gland at rest is to administer its active principle, there is a widely held misgiving that thyroid medication may give rise to exophthalmic goiter. While the efforts of physicians to protect the public from dangerous dosing with thyroid derivatives is commendable, it is time, as Lissner says, that the exaggerated fear of this valuable medicament should be assuaged. It is doubtful if any other product listed in the pharmacopeia when properly used is less harmful or more valuable.

Thyroid should be prescribed initially in small doses, preferably no more than one-fourth grain (0.02 Gm.) of desiccated substance a day. If the patient happens to have a very low titer of circulating thyroxine, even this dosage may evoke an overreaction. This is frankly manifested as nervous tension and often tremors and lacrimation—in short, the patient becomes "jittery." Such a reaction to small doses is, to my mind, pathognomonic of thyroid deficiency and indicates an imperative demand for continuation of the treatment. After a few days' rest it should be resumed at a level of one-tenth grain (0.006 Gm.) daily and gradually increased to the empirical optimum for the patient. The characteristic lag of the reaction and the cumulative effect must be kept in mind. It is also important to

realize that the patient whose tissues are starving for thyroid may have only a narrow zone between too little and too much, hence until the organism becomes adjusted the dosage must be carefully regulated. In this respect every patient is a law unto himself.

OTHER ELEMENTS IN THE PROBLEM OF ORIENTATION

Today the pituitary body is in the focus of medical attention. From this gland are derived a variety of active substances that influence an astonishing number of physiologic functions. That it contributes importantly to growth has been known for many years. Also familiar now is the fact that sexual development and the continuation of sexual activity are dependent on pituitary hormones. For the growth hormone Evans has recently proposed the designation somatotropic. The promotion of sexual activities seems to depend on two gonadotropic factors, one of which stimulates the gametogenic tissues and the other the interstitial tissues of the primary gonads. The morphologic integrity of the thyroid gland as well as its continuing function depends on another principle, the thyrotropic. Similarly, an adrenotropic hormone preserves the integrity of the adrenal glands.

All of these relationships are of course important factors in the everyday work of the pediatrician. Of somewhat special pediatric interest is the recently discovered mammatropic hormone, which has been especially studied by Riddle. It is this agent that sets into activity the ripened mammary glands of the mother. It is due to the beneficent influence of this hormone that problems of infant feeding are usually automatically solved. Riddle's more recent work has suggested, too, that the mammatropic hormone plays a considerable role in the setting up and maintenance of the maternal instincts. Under its influence virgin rats have been made to adopt and mother not only infant rats but also mice, squabs and rabbits. The part that it may play in human psychology presents a problem worthy of consideration. One of the most surprising developments of the past two years is the discovery that the anterior pituitary body plays an important part in the regulation of sugar metabolism. It has now been sufficiently demonstrated that experimental diabetes can be prevented or largely ameliorated by the extirpation of the pituitary gland. This discovery logically compels a restudy of the entire problem of diabetes with due regard to the interglandular relationships. The pituitary gland plays a part, too, in fat metabolism and probably in water metabolism. These are a few of the primary influences of pituitary hormones that can now be recognized. The secondary influences present an almost bewildering array of problems as yet largely untouched and demanding intensive investigation.

Growing enlightenment is increasing the importance that must be ascribed to the adrenal cortex. Deficiency of its secretion retards growth as well as mammary activity, hence it must be considered as a hitherto neglected factor in feeding problems. Firor and Grollman's recent discovery that one of the cortex hormones can be adsorbed on charcoal, in which form it is effective when administered by mouth, promises to be a discovery of major clinical significance. Work in our laboratory (by J. M. Looney) has disclosed an active extract that is apparently neither epinephrine nor so-called cortin, an adrenal cortical extract, and that has a marked pressor influence. This may prove to be of importance in the treatment of conditions of circulatory asthma.

Of special interest to the pediatrician is also the recent discovery of the potency of Hanson's extract of the thymus. Several generations of rats have now been treated with astonishing increasing stimulation of infantile development. While it is true that the work hitherto reported by Rowntree and his colleagues has dealt especially with effects obtained by treating the parents, it is hoped that the extract will prove likewise to have an important direct influence. At any rate Asher has recently reported the discovery of a thymic extract that does directly promote development. Hence there may soon be available in such extracts a valuable medicament for use in cases of delayed development in children. Possibly the thymic principle, too, will lend itself to adsorption on charcoal and thus become available for oral use. As Dr. Rowntree is reporting the work of his group before another section, it would scarcely be gracious for me to develop this topic further.

Passing mention only may be made of recent studies of the parathyroid glands in relation to calcium metabolism and skeletal disorders. Overactivity of the parathyroid glands may give rise to a variety of symptoms, such as joint pains, weakness and polyuria. These manifestations are more common in adults but are occasionally seen also in children. The relationship of parathyroid deficiency to fretfulness and disorders of personality is in need of further study.

COMPLICATING FACTORS IN ENDOCRINE RESEARCH

So much then for orientation.¹ The endocrinologist finds himself almost overwhelmed by the shower of blessings that are falling on him. He is somewhat bewildered by the multitude of fascinating problems that are opening up before him. Among these the translation of the laboratory results into their clinical meanings is especially attractive. But much of this translating must be done by the physicians themselves, hence my chief mission is to utter a Macedonian call.

Even the older endocrinology, however, was far from its final fruition in the field of pediatrics. Possibly in considerable measure because puppies and kittens are not good laboratory animals, the endocrinology of infancy still remains an almost virgin field. Likewise most of the hormone relationships between mother and child require elucidation. How does the infant fare in the transition from maternal endocrine support to hormone autonomy? When does the transition take place? What could be done for a poorly developing infant by endocrine treatment of the mother? What are the indications for supplementing feeding formulas by the direct administration of hormones? Perhaps these problems should be attacked directly rather than through the experimental laboratories. If so, the cooperation of the pediatrician is essential.

There is one aspect of endocrinology, in any case, that necessarily falls on the pediatrician. Medicine is now in a transitional phase. The ineptitude of regarding a man as a mere peripatetic collection of interesting organs is becoming increasingly clear. The personality of their possessor is more important than his organs, no matter what fascinating pathologic condition or secretory versatility they may disclose. By and large, however, endocrinology still remains in the medical Dark Age of preoccupation with organs. There is an urgent need for the study of hormones as factors in personality. This problem must be studied largely

¹ Further details may be found in an excellent series of summarizing articles published in *THE JOURNAL* from Feb. 9 to Aug. 31, 1935, and in the current Yearbook of Neurology, Psychiatry and Endocrinology in the Practical Medicine Series.

on human subjects, and the most fruitful period at which the study can be made is in the developing years when personality is in the making. Although he may need specialized technical assistance, the pediatrician should almost necessarily play a leading role in such studies, and the endocrinologist would be delighted to have him assume primary responsibility.

As the pediatrician undertakes endocrine research, he encounters several complicating factors, some of which have as yet received perhaps too little attention at the hands of clinical endocrinologists.

The very logic of the situation with which the investigator is confronted is likely to be misapprehended. One is prone to look for simple causal sequences. The intrinsically complex nature of the phenomenology can be illustrated by data from elementary inorganic chemistry. If a pinch of table salt and one of potassium bromide are thrown into a glass of water every possible combination of the substances will at once appear—sodium chloride, sodium bromide, potassium chloride, potassium bromide, sodium ion, potassium ion, chlorine ion and bromine ion. When equilibrium is established, the concentration of each constituent of the solution is determined by the concentration of each of the others. Thus, each factor entering into the equation is simultaneously a cause and an effect. One is therefore dealing with a logic of complexes and not merely with a chain of sequences in which causes and effects stay nicely separated. The same is eminently true of the physiology and pathology of hormones—the hormones influence the internal milieu and the milieu influences the actions of the hormones.

A special phase of the complex relationships is that the endocrine organs are immediately interrelated. For example, depression of the anterior pituitary body changes not only the circulating titer of each of its hormones but also the titers of at least the thyroid gland, adrenal cortex and sex glands and perhaps the parathyroid and pancreatic hormones. These changes in turn react on the pituitary body as well as exert their primary effects on the physiologic processes generally. It is therefore practically impossible to distinguish cleancut, uniglandular factors, since complex equilibriums are always involved.

To the clinical endocrinologist the problem of diagnosis is of course of major importance. A few *endocrinopathies* so stamp themselves on the physique as to be recognized even by the tyro, but frank cases of this sort are the exception rather than the rule. Often the history is informative and a skilful physical examination will bring out important diagnostic points, but for the recognition of the more obscure endocrinopathies laboratory aid is indispensable. Presumably each glandular disorder induces a characteristic change in the metabolic picture (equilibrium), and a beginning has been made toward the recognition of these. Thus a combination of depressed basal metabolism, secondary anemia, slow pulse rate, reduced blood pressure, relatively scanty urine, increased blood cholesterol content and depressed urinary nitrogen content commonly signifies thyroid deficiency. A particular need in present-day endocrine research is the further study of the metabolic pictures produced by each glandular disorder. No doubt many intergradations of pictures must always be reckoned with, but at least it may be possible to recognize those of the outstanding primary glandular disorders. An elaborate research of the type suggested was interrupted by the recent untimely death of A. W. Rowe.

A beginning, too, has been made in the direct determination of the hormone content of the blood. A study of the theelin titer is of practical aid in the understanding of menstrual difficulties in girls. Less directly interpretable is the rate of output of theelin in the urine. Further development of assay methods for use in diagnosis would be a valuable contribution to clinical endocrinology.

Collip's recent report of the discovery of antihormones holds out promise of a far-reaching increase of diagnostic resources. If for each hormone there should prove to exist a protective antihormone, it should be possible to isolate these and set up direct systems of titration. It would be theoretically possible—and perhaps practicable—to determine for each individual his precise endocrine status.

This leads to the consideration of another intrinsic complexity of endocrinology. If antihormones actually exist, then any given endocrinopathy is susceptible of two explanations. Take hypothyroidism for example. It may be due, as has hitherto been supposed, to a low output of thyroxine or, on the other hand, to an excess production of antithyroid hormone. It is encouraging to recognize, however, that the two possibilities should lend themselves to relatively simple recognition by therapeutic test. If the thyroxine titer were low, the patient would respond sharply to medication in small doses, if the antihormone titer were high, the threshold of sensitivity to thyroxine would be correspondingly elevated. This is Collip's principle of inverse response.

Another variable in the endocrine equation is the tissue reactivity of the subject. In his studies of endocrine factors in heredity Stockard has been led to the conception that it is the degree of reactivity to the hormones rather than glandular efficiency that is inherited. Riddle has found that some species of doves react to only one-fifteenth as much of a pituitary preparation as is necessary to give a reaction in other strains. The occurrence of circumscribed areas of myxedema in patients showing clinical hyperthyroidism affords a particularly striking example of tissue variability. At the present time this factor seems to be of theoretical rather than practical interest, but, should exact methods of diagnosis by blood assay be developed, it will need to be taken into account and compensated for in determining dosages. Perhaps even now the principle has some meaning as explaining the mixture of symptoms of glandular hyperactivity and hypo-activity that are encountered when a patient is in a transition stage of glandular involution, e. g., in the later stages of acromegaly.

One cause of tissue refractoriness might be vitamin deficiency. In the absence of adequate supplies of vitamin D, parathyroid extract is ineffective, and this fact may conceivably illustrate a principle of wide applicability. The converse relationship may also hold. Hartman has found that vitamin assimilation is influenced by the amount of adrenal cortical hormone available to the organism. The same may be true of other hormones. The pediatrician seems to be in a favorable strategic position to investigate the hormone-vitamin relationships.

Having taken into account as best one can the various factors that might give rise to endocrine deficiency, actual or virtual, and having determined on the hormone indicated in any given case, the question of dosage arises. This must be determined empirically for each subject. The reaction threshold, as previously suggested, can vary widely from case to case. One of

my adult subjects reacts sharply and objectively to thyroid in dosage of one-third grain (0.02 Gm.) a day. Sleeper and I studied a schizophrenic patient who took 60 grains (4 Gm.) a day over a period of weeks and with only minimal effects.

The question of dosage is important not only because of the necessity of adjusting it to optimum efficiency but because of the danger of evoking the production of antihormone or, at least, tissue refractoriness. Lissner has reported a case of tetany in which the outcome was fatal because of the fact that the patient ultimately became unresponsive despite the use of enormous doses of parathyroid extract. Such refractoriness may have arisen because of the unphysiologic way in which the hormone reached the circulation. When several hours' supply is administered at once, a succession of feasts and famines is set up that is but a poor imitation of a smooth natural inflow—and that perhaps delicately regulated to the bodily need prevailing at any given time. It is rather probable in such cases that the periodic subjection of the body to excessive hormone influence sets up a protective outpouring of antihormone, and that a cumulative vicious circle is thus established. It would seem desirable, therefore, to incorporate hormone preparations that are to be given hypodermically in an oil menstruum or an emulsion so that absorption will take place more evenly than when aqueous solutions are used. As an immediately practical point, evidence has recently been offered that the total effect of a given amount of hormone is severalfold greater when given so as to promote slow absorption. Small doses frequently repeated are also more effective than large doses at longer intervals. The explanation is probably the same as in the case just discussed. Both on empirical and on theoretical grounds, then, the smallest dosage of a given preparation that will produce the desired effect should be used. As an empirical rule, also, the omission of medication for one week of each month seems to be more effective than continuous medication. Possibly the vacations permit the body to dispose of accumulated antihormone.

Another reason for concern about dosage is that some hormones—perhaps all—are diphasic in their influence. Thus, thyroid gives either anabolic or catabolic effects depending on the amount used. As Jellinek and I as well as others have shown, it promotes the formation of red blood cells in small or moderate doses but leads to secondary anemia if too vigorously administered. Other examples of reversal of effects with change of dosage could be cited, but further research is needed to determine to what extent the diphasic reaction is characteristic of hormones in general. It is not unlikely that the operation of this principle would account in numerous instances for discrepancies in the results reported from glandular therapy.

To round out the tale of difficulties, attention may be called to the fact that glandular imbalance gives a picture that is decidedly different from that of a compensated deficit or plethora of hormone. This is most clearly seen in the reaction to ovarian extirpation in middle aged patients or in the nervous tension of the menstrual period. The manifestations are due to ovarian deficiency, but that condition, when compensated as in girlhood or old age, is benign. Merely to overcome a given glandular deficit by substitution therapy is in principle fairly easy, but to reestablish a delicate glandular balance presents a much more difficult problem. This principle comes into practical consideration when the pediatrician undertakes the hormone treatment of

menstrual difficulties in girls. The cycle depends on a rather complex interaction of hormones, and each addition or subtraction disturbs the balance among them. Ideal therapeutic results can be expected only when the distortions of the normal formulas are recognized and individually corrected. Since the relationships vary from period to period during the cycle, a highly complex theoretical problem is thus presented. Practically, however, nature seems to be able to make out fairly well on a makeshift basis and, if a few of the major abnormalities are artificially corrected, to make the other adjustments spontaneously. Otherwise endocrine therapy would never offer better than a forlorn hope.

So much, then, for the outstanding theoretical and practical difficulties in endocrine research. The situation is and must remain complex. The difficulties have always existed—hence, no doubt, the slowness with which advancement in practical endocrinology has occurred. Perhaps the frank recognition of them would afford better technics for dealing with them and lead to an acceleration of progress.

In the last analysis no amount of knowledge of the physiology of the rat—or even the monkey—will in itself solve the pediatrician's problems. At best, only principles and "leads" can be derived from studies on the lower animals. The ultimate human problems must be solved in human terms. Hence the only hope for the final understanding of the endocrinology of infancy and childhood is in research conducted by the pediatricians themselves. The old adage is apposite. You can lead a horse to water but the deglutition must be voluntary. If this paper has served in any way to make the beverage seem more attractive, its purposes will have been served. Seriously, it seems imperative that the pediatricians as a group should become more vigorously concerned with the problems of endocrinology. In conclusion may I reiterate a hope that in the study of these problems the most important of all, the influence of the hormones on personality, will not escape judicious and critical attention.

SUMMARY

The thyroid gland, despite numerous recent observations on other glands, is still the one of most importance to the practical pediatrician. Minor degrees of thyroid deficiency as causes of disorders in childhood are of frequent occurrence.

The derivation of active substances from the anterior lobe of the hypophysis has given somatotrophic, gonadotrophic, mammatrophic, thyrotrophic and adrenotrophic fractions, each of which presumably enters into the problems of the pediatrician. The influence of the pituitary body on carbohydrate, fat and water metabolism demands practical consideration. The relation of the adrenal cortical hormones to growth and lactation is of special pediatric interest, as is also the newer work on thymic extracts. The influence of hormone factors on the personality demands study.

Some of the difficulties of endocrine research are the complex nature of the relationships involved, the difficulties of diagnosis, the recently reported existence of antihormones, variations of tissue reactivity, the diphasic influence of individual hormones and the special effects of glandular imbalance.

The responsibility for the final solution of the endocrine problems of infancy and childhood devolves primarily on the pediatricians.

A HEMOLYTIC BLOOD TRANSFUSION REACTION WITH OLIGURIA

H G McCANDLESS, MD
CINCINNATI

My purpose in this paper is to present a case in which recovery followed a hemolytic blood transfusion reaction with suppression of urine

In 1931 Bordley¹ presented a review of the literature and a report of cases of hemolytic transfusion reactions with oliguria, and he added three more from the records of the Johns Hopkins Hospital. From the study of these seventeen cases, according to Bordley,¹ a clinical syndrome that is characteristic of the reaction may be outlined as follows (a) Immediately after the transfusion there is a sharp febrile reaction, followed frequently by hemoglobinuria and invariably by suppression of urine, (b) there is an interval of several days during which there is symptomatic improvement but continued oliguria, and (c) after that interval the characteristic symptoms (agitation or drowsiness followed by uremia with convulsions and coma) develop rapidly and usually reach their peak eight days after the transfusion. Progressive uremia is the picture in the fatal cases, while profuse diuresis accompanies recovery.

The pathologic picture as described by Baker and Dodds² and Witts³ and as discussed by Bordley¹ is one of central or nodular necrosis of the liver, pale edematous kidneys, with the collecting tubules filled with cellular debris (desquamated tubular epithelium plus red blood cells and lymphocytes) and degenerative changes in all tubular epithelium.

In the case reported here the clinical picture was typical of a hemolytic blood transfusion reaction with oliguria.

A Negro man, aged 42, was admitted to the Cincinnati General Hospital at 8 11 p m, Jan 20 1935. Approximately one-half hour earlier he was cut on the right forearm with a razor. There was a profuse hemorrhage of the arterial type, and the patient was brought to the hospital by a friend who wrapped the bleeding arm in a towel. During transportation the patient lapsed into unconsciousness and did not react until his arrival in the receiving ward. Examination revealed a laceration 12 inches (30 cm) long over the volar surface of the right forearm. The radial artery and numerous other smaller arteries were clamped the arm was wrapped in sterile dressings, and shock treatment was instituted. The blood pressure was 80 systolic, 50 diastolic on admission, the patient's skin was cold and clammy, with profuse perspiration. Seven hundred cubic centimeters of a 5 per cent solution of dextrose was given intravenously with the patient in shock position, and external heat applied. Later the patient's blood pressure was found to be 50 systolic, so 500 cc of a 5 per cent solution of dextrose with 32 mg of acacia was given. The blood pressure rose to 95 systolic, 60 diastolic. The patient was moved to the ward at 11 p m. The white blood cell count was 18,000, urine analysis showed a specific gravity of 1.016 and an alkaline reaction. The urine was straw colored and contained no albumin. The amount of sugar was recorded as 3+ after the administration of dextrose. The microscopic examination was negative. At midnight 500 cc. of a 5 per cent solution of dextrose with 32 mg of acacia was again given intravenously because the blood

pressure had dropped to 60 systolic, 40 diastolic. At the completion of the injection the blood pressure was 100 systolic, 60 diastolic. The patient complained of nausea but did not vomit.

At 1 a m the patient's blood was typed and cross matched. His blood and that of the donor were both type IV. Cross matching showed no agglutination at the end of one-half hour. At 1 45, 500 cc of citrated blood with 300 cc of physiologic solution of sodium chloride was given. The pulse rate throughout the transfusion was 88. The patient made no complaints and showed no signs of what might be interpreted as an immediate reaction.

The patient was sent to the operating room at 2 30 a m. Under gas anesthesia the wound was thoroughly cleansed and the edges were excised. Examination revealed division of the radial artery and of a number of tendons, and partial division of the median nerve and transverse carpal ligament. The tendons and nerve were repaired with fine black silk, the subcutaneous tissue was sutured with interrupted catgut, and the skin closed with interrupted silk. The patient was returned to the ward in good condition.

At 9 30 a m the patient was taking fluids well with slight nausea. He vomited a small amount of greenish material, the temperature was 103 F. At 2 30 p m the general condition was much improved. The blood pressure was 110 systolic, 70 diastolic, temperature 101.4 F, pulse rate 112 and respirations 24. Tetanus antitoxin, 1,500 units was given subcutaneously.

On January 22 the patient urinated for the first time after the operation (forty nine hours previously). The bladder had not been distended and there was no pain or tenderness in the costovertebral angles. Urinalysis showed 500 cc. of reddish black urine 3+ albumin occasional white blood cells, 4 or 5 red blood cells per high power field an occasional granular cast and a 4+ benzidine reaction. Ammonium chloride, 30 grams (2 Gm) three times a day was ordered. Fluids were to be forced.

On January 23 the patient did not urinate. He vomited without nausea 700 cc. Fluids taken by mouth amounted to 2,800 cc. The blood urea nitrogen was 80 mg per hundred cubic centimeters. An intravenous injection of 800 cc. of physiologic solution of sodium chloride and 50 cc. of a 50 per cent solution of dextrose was given.

On January 24 the patient voided 500 cc. of urine. A cough developed and a small amount of blood streaked sputum was expectorated. A urine examination showed reddish brown urine albumin 3+, many red blood cells and occasional white cells. A blood count showed 9,900 white blood cells and 2,740,000 red blood cells. Fifty cubic centimeters of a 50 per cent solution of dextrose was given intravenously.

On January 25 the patient vomited 500 cc of greenish material without being nauseated. There was an output of 175 cc of reddish brown urine, which showed albumin 3+ and a 2+ benzidine reaction. There were an occasional granular cast and white blood cell. The blood urea nitrogen was 100 mg per hundred cubic centimeters, carbon dioxide, 31 volumes per cent. The red blood cell count was 2,600,000. Roentgen examination of the chest was negative. Hot moist packs were applied to the lumbar region 1,000 cc. of Fischer's solution was given intravenously with 100 cc. of physiologic solution of sodium chloride. This was followed in twenty minutes by a severe chill, which lasted for fifteen minutes. The blood pressure rose to 180 systolic, 90 diastolic. The temperature after the chill was 102 F.

January 26 the patient had no complaints. He vomited without being nauseated a total of 600 cc. The total urinary output was 75 cc of amber urine with albumin 2+, benzidine 0, many white blood cells and a few granular casts. He again expectorated a small amount of blood streaked sputum, which was negative for tubercle bacilli. The blood urea nitrogen was 115 mg per hundred cubic centimeters, carbon dioxide, 30 volumes per cent. Eight hundred cubic centimeters of a 10 per cent solution of dextrose was given intravenously.

January 27 the patient appeared somewhat drowsy and vomited four times a total of 725 cc. of material, which showed a 3+ benzidine reaction. The total urinary output was 405 cc. The temperature was normal, having shown a gradual curve

downward from the postoperative temperature of 103 F. The patient continued to have blood streaked sputum. The urine was amber with 2+ albumin. There were occasional granular casts. Five hundred cubic centimeters of a 10 per cent solution of dextrose and 400 cc of a 5 per cent solution were given intravenously.

January 28 the patient was moderately stuporous but he responded well, had no complaints and breathed comfortably. There was moderate pitting edema of both legs to the thighs.

Chart 1—Total daily fluid intake and output

for the first time. There was a fluid wave in the abdomen and a moderate right hydrothorax. The ophthalmoscopic examination was negative. The patient vomited four times a total of 1,275 cc., one specimen of which contained a moderate amount of bright red blood. He voided a total of 465 cc of urine showing a specific gravity of 1.010, an acid reaction 2+ albumin, clumped white blood cells, no casts and a trace of benzidine. The blood urea nitrogen was 135 mg per hundred cubic centimeters, carbon dioxide, 20 volumes per cent. The patient had had a total intake of approximately 30,000 cc and a urinary output of approximately 2,200 cc from the time of admission, with only slight edema of the legs. Fifty cubic centimeters of a 50 per cent solution of dextrose was given intravenously. The Karell diet replaced the regular diet. Sodium bicarbonate, 30 grains (2 Gm.), was given four times a day. The ammonium chloride was discontinued. The wound was dressed and part of the silk skin sutures was removed. The wound was well healed, with no evidence of infection or hematoma.

January 29 the patient was moderately stuporous but was rational and offered no complaints. He expectorated a small amount of blood streaked sputum and vomited 200 cc. of greenish fluid without blood. The urinary output was 660 cc., which showed a specific gravity of 1.015, light yellow color, alkaline reaction, no albumin and occasional white blood cells, no blood by benzidine test and no casts. The patient's blood and blood from the donor were typed and cross-matched again. Both were type IV and the match was perfect at the end of eight hours. Fifty cubic centimeters of a 50 per cent solution of dextrose was given intravenously. The wound was healing well.

January 30 the patient offered no complaints. His general condition was unchanged. The edema of the legs had neither progressed nor receded. He vomited 200 cc. of greenish fluid (this was the last time that he vomited). The urinary output was 1,500 cc., and showed only a few white blood cells. The blood urea nitrogen was 110 mg per hundred cubic centimeters, carbon dioxide, 17 volumes per cent. The patient had a rather severe nosebleed which lasted for twenty minutes and was stopped by packing. Fifty cubic centimeters of a 50 per cent solution of dextrose was given intravenously.

January 31 the patient was free from edema, muscular twitchings were noted over the body and extremities. There was no increase in drowsiness. The urinary output was 1,200

cc of normal urine. Fifty cubic centimeters of a 50 per cent solution of dextrose was given intravenously. The diet was changed from a Karell to a low protein salt-free diet with a fluid intake limited to 1,000 cc. daily.

February 1 there were no subjective complaints or objective changes. The urinary output was 2,600 cc. of normal urine. The blood urea nitrogen was 145 mg per hundred cubic centimeters, carbon dioxide, 25 volumes per cent. Fifty cubic centimeters of a 50 per cent solution of dextrose and 1,000 cc of Fischer's solution were given intravenously. The wound was completely healed.

February 2 all muscular twitching had ceased and there was no drowsiness. The patient wanted to get up and stated that he felt "fine." He voided 2,725 cc of normal urine. The blood urea nitrogen was 165 mg per hundred cubic centimeters and carbon dioxide was 28 volumes per cent. The blood count showed 1,000,000 erythrocytes. The patient's blood was typed and cross-matched for a transfusion. His blood and that of the donor were of type IV, they cross-matched perfectly at the end of one-half hour at room temperature, and no agglutination was noted after one hour in the incubator. He was given 50 cc of a 50 per cent solution of dextrose intravenously. Six hundred cubic centimeters of citrated blood with 300 cc of saline solution was given later with no immediate reaction.

February 3 there was no change in the condition. The patient voided 3,175 cc of normal urine. Fifty cubic centimeters of a 50 per cent solution of dextrose was given intravenously.

February 4 the patient remained free from edema and made no subjective complaints. There was no drowsiness or muscular twitching. He voided 2,800 cc. of normal urine. Fifty cubic centimeters of a 50 per cent solution of dextrose was given intravenously.

February 5 there was no change noted. The patient voided 2,125 cc of normal urine. The blood urea nitrogen was 135 mg per hundred cubic centimeters, carbon dioxide, 43 volumes

Chart 2—Total daily urea nitrogen and carbon dioxide

per cent. The red blood cell count was 3,400,000. Fifty cubic centimeters of a 50 per cent solution of dextrose was given intravenously.

From February 5 improvement was noted. February 9 the patient sat up in a chair without any apparent ill effect. The urine remained normal except for an occasional trace of albumin. The blood urea nitrogen was 105 mg per hundred cubic centimeters, carbon dioxide, 53 volumes per cent. No special treatment had been given since February 5.

February 12 the patient had a small localized abscess over the left frontal area, and an elevation of temperature to 100 F.

The blood urea nitrogen was 24 mg per hundred cubic centimeters, carbon dioxide, 46 volumes per cent. Hot saline solution compresses were applied to the abscess. The regular diet was given and fluids were taken as desired. Iron and ammonium citrate, 30 grains (2 Gm.), was given four times a day.

February 13 the left supra-orbital abscess was incised and drained. A phenolsulphonphthalein test showed a 35 per cent output in the first hour and 15 per cent in the second hour, a total of 50 per cent in two hours.

February 14 the patient was up and about with no complaints. Urinary concentration tests showed the following specific gravity values at 7 45 p m 1002, 9 45 1004, 11 30 1005, 3 a m 1005, 5 1005, 8 30 1006, 10 30 1008.

On February 15 the following specific gravity values were noted in the dilution test at 9 10 1007, 10 10 1000, 11 10 1001. These were the only adequate specimens obtainable.

February 16 the patient wanted to go home, said he felt well and had no complaints of any kind. The blood urea nitrogen was 14 mg per hundred cubic centimeters, carbon dioxide, 54 volumes per cent.

February 18 the patient was discharged from the hospital with no subjective complaints or objective signs referable to the blood transfusion reaction. The last urinary specimen was clear and straw colored and showed an alkaline reaction, specific gravity 1005, a trace of albumin, no sugar, an occasional white blood cell, no red blood cells, no casts and a negative benzidine reaction.

Since Bordley¹ reported his review of seventeen cases in 1931, Payne⁴ has reported a typical case from Guy's Hospital in which the donor and the recipient were of type IV before transfusion. On a repeated cross-matching and typing after the transfusion they were found to belong to the type IV group and cross-matched perfectly. The patient died on the third day after transfusion, presenting a clinical picture of suppression of urine and uremia.

Von Deesten and Cosgrove⁵ have also reported a case in which a transfusion of 750 cc of whole blood was followed immediately by a reaction characterized by severe headache and pain in the lumbar spine and both legs. Shortly afterward there was vomiting of blood streaked vomitus. Later hematuria, hemoglobinuria and oliguria developed. The delayed reaction reached its peak on the ninth day. The clinical observations were those of severe uremia with retention of urea nitrogen and creatinine, rigidity of the neck, convulsions and coma. Previous to this time the treatment had included the intravenous and intramuscular administration of magnesium sulphate and the intravenous administration of dextrose without beneficial results. Venesection of 450 cc of blood followed by an intravenous injection of 500 cc of physiologic solution of sodium chloride resulted in immediate cessation of the uremic symptoms and the patient made a slow but uneventful recovery.

Johnson and Conway⁶ have reported three cases in which there were typical reactions, Stewart,⁷ two cases, Parr and Krischner⁸ and Baron⁹ have each reported one case, making an addition of ten cases to the literature since 1931.

A study of these twenty-nine cases, including the case reported in this paper, reveals the following:

- 1 The amount of blood given varied from 40 to 1,000 cc.
- 2 The citrate method was used thirteen times and whole blood ten times, the method not being specified in five instances. Once blood from the peritoneal cavity in a case of ruptured ectopic pregnancy was given.
- 3 There were eighteen deaths and eleven recoveries, a mortality rate of 62 per cent.
- 4 The peak of the reaction occurred from the third to the eighteenth day, excluding the patients who died at four and one-half and eight hours, the average time for the peak of the reaction was the ninth day.
- 5 Death followed transfusions varying from 230 to 1,000 cc., whereas recovery followed transfusions varying from 40 to 750 cc.

Polayes and Lederer¹⁰ report a study of 2,500 blood transfusions and classify the causes of reactions as follows:

I Incompatibility

(a) Errors in grouping

- 1 Poor technic.
- 2 Use of low titered or contaminated serum.
- 3 Weak agglutinins or agglutinogens in the recipient's blood.
- 4 Pseudo-agglutination.
- 5 Auto-agglutination, cold agglutination and subgroups.
- 6 Anomalous or atypical agglutination.
- 7 Contamination of recipient's blood by bacteria.

(b) Indiscriminate use of the universal donor

(c) Immune iso-antibodies and hemolysis

- II The use of unclean apparatus
- III The use of citrate solutions
- IV Incipient coagulative changes in the transfused blood.
- V Allergic phenomena in the recipient.
- VI Systemic diseases in the recipient
- VII Transmission of disease to the recipient

In order to place the present case in this classification, it must be classified as a reaction due to hemolysis in the recipient's blood, and thus it falls into the group of incompatibilities which cannot be forecast from the simple, direct cross-matching of the donor's and the recipient's blood.

This type of blood transfusion reaction is rare, as shown in the report by Witts³ of a series of 3,430 blood transfusions without a single case of hemolytic reaction. It is a very serious reaction, as death has occurred in 62 per cent of all reported cases. In view of this fact one should consider the advisability of adding to the cross-matching procedure a test for hemolysis between the donor's and the recipient's blood.

SUMMARY AND CONCLUSIONS

- 1 A typical case of a hemolytic blood transfusion reaction with oliguria was studied, together with twenty-eight cases that have previously been reported.
- 2 The peak of the reaction after the transfusion usually occurs on the ninth day.
- 3 In the twenty-nine cases reported there were eighteen deaths, a mortality of 62 per cent.
- 4 Neither recovery nor death depends on the method of the transfusion or the amount of blood given.
- 5 The reaction appears to be one of hemolysis and cannot be forecast by cross-matching.

ALLERGIC REACTIONS ASSOCIATED
WITH COHABITATIONWARREN T VAUGHAN, MD
AND
RICHARD W FOWLKES, MD
RICHMOND, VA

The possibility of sensitization to emanations from individual human beings has been suggested in the past but so far as we have been able to discover, no clearly authentic case of this type has been reported. Over quite a period of time, one of us included tests for sensitization to human hair in the routine sensitization studies. When, after several hundred such tests, it was found that no case had given a positive reaction, the use of this allergen was discontinued. One young woman with dermatitis from allergy to silk found that each time she had her hair trimmed the dermatitis over her neck and shoulders flared up. She was sensitive by scratch test neither to stock human hair nor to an extract of her own hair. A patch test with her own hair was negative. No special washes or other treatment of the hair was used at these times.

In the cases of supposed sensitization to human beings, it seems much more probable that some allergenic substance in the immediate environment of the person under suspicion is the etiologic agent. The following cases tend to confirm this premise.

CASE 1—A woman, aged 38, perennially asthmatic, found that her asthma was increased when she slept with her husband. Among other things she was found sensitive to extract of tobacco smoke. Her husband was a heavy smoker. Following desensitization with tobacco smoke extract, her nocturnal asthma was decidedly improved. The patient was primarily intrinsically asthmatic, also sensitive to a number of extrinsic allergens, and, on the whole, relief from asthma was not satisfactory. At the same time, relief from the tobacco smoke factor at night was sufficiently marked to be convincing.

Other allergens may act in the same way in cohabitants. Thus, a young woman in our experience, sensitive to horse dander, had attacks of asthma whenever her brother went horseback riding and subsequently sat near her without first bathing and changing his clothes. Further possible applications of this type of exposure are obvious.

CASE 2—A man, aged 30, who had had no previous allergic manifestations except an occasional attack of migraine, was married in the summer of 1934. About two months later a papular, pruritic dermatitis appeared on the legs, which soon involved both lower extremities and the lower part of the abdomen and back. The dermatitis became very extensive and was accompanied by considerable edema. The patient was found sensitive to wheat and silk. At first he stated that he did not have any direct contact with silk but later recalled that his wife wore a silk nightgown. She changed to linen night clothes and the patient left wheat out of his diet. The dermatitis was promptly relieved. After two weeks when it had cleared up satisfactorily, his wife again wore a silk nightgown. The next morning he had a mild return of the dermatitis. Since then she has continued to wear linen and the dermatitis has not recurred, except on one occasion when he experimented with the eating of wheat.

CASE 3—A man, aged 26, first seen in December 1933, suffered from a dermatitis involving both feet and ankles. He also gave a history of hay fever and was found sensitive to a number of pollens. *Trichophyton* was found in some of the scales from his feet and he was strongly sensitive to *trichophyton* extract. Among the foods he gave several positive reactions and he was placed on a diet. With dietary avoidances

local treatment and *trichophyton* desensitization the condition gradually cleared up, over a period of several months. When recovery was sufficiently advanced he experimented with additions of food to his diet and found that he could eat all positively reacting foods with impunity except lemon and chocolate. These he still avoids after fifteen months. When, occasionally, he inadvertently ingests one or the other of these he has a return of the dermatitis.

The patient was married in the summer of 1934. For economic reasons it was felt that there should be some delay in the rearing of a family, and contraceptives were therefore employed. The first contraceptive used was a vaginal suppository with a base of oil of theobroma. Each time, within twenty-four hours after coitus, the patient experienced a disagreeable and embarrassing acute dermatitis of the genitalia. After a few weeks he recalled his sensitization to cocoa and, suspecting oil of theobroma as an etiologic factor, he changed the contraceptive to a contraceptive jelly. Since then he has had no return of these symptoms.

CASE 4—A married man, aged 50, coming to the office in July 1934, complained of intense burning stinging and itching of the shaft of the penis, which had started about six hours earlier, coming on about 4 o'clock in the morning. On examination the shaft and prepuce were swollen, edematous and very red indicative of the acute inflammation present. When the patient was questioned it was learned that he had had intercourse with his wife on retiring the night before and, as had been his custom for about twenty-five years, had used a condom. The patient then recalled that for the preceding two or three months he had had similar attacks of dermatitis on the penis, and for the first time he recalled that it always appeared after intercourse. A patch test was done with one of the condoms, which came out of the same box as the one he had used the night before. The patch test was applied to the inner side of the arm and another to the inner side of the thigh. Both of these patch tests, when removed twenty-four hours later, showed a good positive reaction. Since that time contraceptive jellies have been used and the patient has had no further trouble.

COMMENT

These cases illustrate the fact that symptoms associated with contact with some single individual are probably due to some allergenic substance in the person's immediate environment. In view of present immunologic concepts, this seems much more logical than some curious and unexplained sensitization to what are essentially homologous proteins. A few similar cases have been reported.

Rattner and Pusey¹ report the case of a young married man with dermatitis due to a certain perfume which his wife was in the habit of using.

Ford² reports a case of contact dermatitis due to quinine, confirmed by a patch test positive to the drug, and manifested by a vesicular dermatitis of the face, scalp and neck following two applications of Kreml Hair Tonic. Several months later this patient returned with a similar dermatitis involving the penis, scrotum, eyes, cheeks, ears and sides of the neck. It first started on the genitalia. This time the etiologic agent was found to be a contraceptive vaginal suppository containing quinine bisulphate and boric acid in a base of oil of theobroma.

Metzger³ has described an interesting case of asthma from cohabitation. A sea captain was always free from asthma when on his vessel and on the high seas. Within half an hour or so after landing at port, any port, he would have a violent attack of asthma. The

only substance to which he was found sensitive was orris root. The captain's "on-shore" proclivities may be easily deduced.

Duke⁴ has described the case of a woman with asthma following coitus, which the husband thought due to sensitization to semen. Duke, however, concluded that it was a case of physical allergy due to heat and effort.

SUMMARY

So-called allergy to human beings can probably always be explained as due to some allergenic substance in the person's immediate environment. In some illustrative cases reported allergic reactions following concubency or coitus have been explained in this manner.

VARIABILITY IN THE STRENGTH OF TOXIN USED FOR THE DICK TEST

EMANUEL FRIEDMAN, MD
ARTHUR L. ESSERMAN, MD
AND
MAX M. GINSBURG, MD
DENVER

During the last two years we have encountered from time to time in the course of our work of immunization against scarlet fever, both by the hypodermic and by the intranasal method, reactions that appeared inconsistent and strikingly at variance with what had been anticipated. In our¹ publication on the subject we endeavored to account for such unexpected results by advancing the hypothesis that in some individuals the level of immunity to scarlet fever may vary from time to time, under the influence of factors beyond our knowledge. In the last six months the conviction has been forced on us that other factors play a part in the causation of these unexpected reactions. The experiences that led to this conclusion deserve, we believe, to be set forth in detail.

During November and December of 1934 we obtained from the use of one particular batch of Squibb's Dick Toxin uniformly strong positive reactions, and it was noted that almost every applicant for active immunization developed a positive reaction. The test was applied to a number of individuals who had had scarlet fever and it was most disconcerting to find that these too, in a large percentage of instances, yielded a positive outcome. Our colleagues using the same brand of toxin reported similar experiences. We communicated our difficulties to the manufacturers of this product and were informed that investigation showed this particular toxin to conform to established standards of potency. Needless to say that all tests had been performed with meticulous regard for every detail.

Despite the assurance of the manufacturers, we were convinced that this particular toxin was many times more potent than the Dick toxin we had used on previous occasions.² Our confidence in the reliability of the Dick test as an index to scarlet fever immunity had been shaken somewhat. Nevertheless, we felt quite certain, and are as fully convinced today, on the basis

of personal experience and review of the literature, that the Dick reaction is, in the main, a dependable indicator of scarlet fever immunity and that successful immunization in positive reactors can be achieved by means of the injection or nasal insufflation of sufficient amounts of the specific scarlet fever toxin.

With the use of a new supply of toxin, our work progressed more satisfactorily for a time. However, we were destined to be disappointed again before long. On March 15, forty-one positive reactors at the Preventorium of the National Jewish Hospital received their initial inoculation of scarlet fever toxin by the hypodermic route. Successive weekly injections were given in accordance with the directions of the Dicks. On May 10, thirty-eight of these children were available for retesting, and twenty-three, or 60.5 per cent, gave a negative reaction. On May 11 the fifteen children who were still positive received a sixth injection of 80,000 skin test doses. On June 8, thirteen of these fifteen presented themselves for Dick testing. To our surprise, all thirteen were again positive, and what was even more disconcerting was to find the reactions in most instances of considerably greater intensity than the initial reactions. Moreover, the reactions persisted for from seventy-two to ninety-six hours. Mulford's products were used both for inoculation and for Dick testing. However, the toxin used for the final Dick test was purchased at a later date than the toxin used for the preliminary and second tests.

The following day, June 9, the very same toxin which produced these marked reactions was used in testing seven children who had shown a negative reaction on February 7. Two of these seven now presented a positive Dick. On the same day a second group of seven children who were positive on February 7 and had received five injections of toxin and had given negative reactions on May 10 were likewise retested with the same potent toxin. Four now showed positive reactions.

These results left no room for doubt that this particular toxin possessed a much higher degree of potency than that used in February and March. Thus, for the second time we came across a toxin that unmistakably failed to conform with established standards for potency.

In order to confirm this impression, we selected five children who were still positive (June 9) with this inordinately powerful Dick toxin of Mulford after having received six immunizing doses of toxin, and tested them on June 10 with a Squibb preparation which we had been using for some weeks in our office. Three of these were now negative, and two yielded mildly positive reactions. As a further check twelve of the children inoculated with six doses of toxin and still positive with Mulford's were again tested with a newly purchased Squibb toxin. Only one of these twelve children showed a positive reaction.

In other words, the same group of children tested within a period of a few days with Dick toxin obtained from three different sources yielded results that varied within wide limits. This justifies the conclusion that Dick toxin designed to test the susceptibility of individuals to scarlet fever, and to determine the effectiveness of active immunization against this disease, possesses at times varying degrees of potency, and its use may lead to erroneous conclusions.

We were curious to determine whether the application of this inordinately powerful toxin of Mulford would yield an equally high incidence of positive reactions in another group of children. We could see no

⁴ Duke, W. W. Clinic before the Virginia Carolina Tri State Medical Association Greenville S. C. February 1933.

¹ Friedman, Emanuel, Esserman, A. L. and Black, M. H. Active Immunization Against Scarlet Fever by the Nasal Route. *J. Pediatr.* 5: 504 (Oct.) 1934.

² Of sixteen children who were negative with three different makes of Dick toxin twelve yielded (June 28, 1935) strong positive reactions with this preparation.

reason for a different outcome. Accordingly, on June 28 we tested nineteen children free from acute infections, in residence at the Children's Hospital. The Mulford toxin bore the same serial number and expiration date as the one that gave rise to the strong reactions at the previctorium. As controls, we elected to use Squibb's and Parke, Davis's Dick toxin. To our utter amazement the reactions obtained from the application of these three different toxins were almost identical. Fifteen were negative to all three tests, four were positive to all three, with almost no variation in the degree of intensity, and in one instance Squibb's yielded a borderline positive, whereas the two other toxins proved negative.

This indeed was an unexpected outcome. If the Mulford toxin used at the Children's Hospital possessed—as it should—the same high potency as the product bearing the identical serial number and expiration date used at the previctorium, why did we not get a higher percentage of positives with the Mulford preparation than with the controls—as was the case at the latter institution? Are we not justified in our belief that the two products which should have possessed the same degree of potency were actually quite dissimilar in this respect?

These experiences make the conclusion inescapable that the Dick toxin manufactured by various pharmaceutical concerns lacks uniformity of composition. (Parenthetically, it may not be out of order to ask whether the toxin furnished for the active immunization against scarlet fever may not likewise vary in potency.) This doubtless constitutes a serious hindrance to the widespread practice of active immunization against scarlet fever. It is incumbent on the biologic houses to correct this unfortunate situation speedily and thereby pave the way for a more general acceptance by the profession of an effective prophylactic measure against a dreaded disease.

Furthermore, attention should be directed to the fact that in our limited experience approximately 12 per cent of a group of children reacted to the intradermal introduction of 0.1 cc of phenol in the dilution of 0.4 per cent. This is the amount of phenol added to the Dick material as a preservative. Hence the advisability of controlling the Dick test by means of the injection of phenol in the concentration mentioned in order to eliminate false positive reactions.

And, again, it is quite likely that a certain percentage of positive Dick reactors owe their reaction to the protein substances found in the medium on which the streptococci has been grown, rather than to the specific toxin. This medium should therefore be made available so that we may be able to differentiate these protein reactions from those actually due to the specific toxin.

CONCLUSION

There is too great a variability in potency of the Dick toxin available at present, to make it serve as a dependable index to the presence or absence of immunity to scarlet fever.

Until this toxin is properly standardized and all commercial toxins are of uniform strength, it is impossible to determine with any degree of accuracy to what extent attempts at active immunization have been successful.

It would appear, therefore, that the present scheme of active immunization against scarlet fever rests on an insecure foundation.

Clinical Notes, Suggestions and New Instruments

WHEAT HAIRS AND DUST AS A COMMON CAUSE OF ASTHMA AMONG WORKERS IN WHEAT FLOUR MILLS

W. W. DUKE, M.D. Kansas City, Mo.

In the study of four consecutive cases of asthma observed among workers in wheat flour mills, I have been able to trace the source of illness. I believe, to sensitization to wheat hairs or the surface scales of wheat or both. I believe that wheat hair is probably the morphologic structure which is responsible for a majority of cases of wheat asthma among millers.

The four patients all gave a like history of finding that they were subject to asthma while working in wheat mills, especially on windy days and when they worked in certain rooms in which they were exposed to the dust that came from the first cleaning of the wheat grain. The most severe attacks followed mishaps

Fig. 1—Longitudinal and cross section of a grain of wheat. Note sharp pointed hairs at the top of the longitudinal section, which are broken off at the first cleaning of the wheat grain. In the original from which this reproduction was made the longitudinal section was magnified 70 diameters and the cross section 30.

in the machinery of the mill or the cleaning of apparatus or rooms that exposed the workers to unusually large amounts of this dust. Depending on the degree and duration of exposure attacks of asthma would follow, which would last from a day to a week or more and vary from cough or marked asthma to a completely prostrating asthma that was difficult to relieve by therapeutic measures.

Apparently sensitization came on after several years' work in a mill and gradually increased in severity until it resulted, in two cases, in an illness that caused the patients to quit milling in spite of treatment with extract from wheat hairs and dust, which reduced the frequency and severity of their attacks. One patient was so disabled at the age of 53 by a complicating

emphysema that he was granted disability insurance. This patient was not grossly affected by any agent other than wheat dust.

The patients were all tested with extracts of the different fractions of wheat obtained in the process of milling, namely, dust obtained from the first polishing of wheat, from bran and germ, from the different grades of flour, from the dust obtained from the different localities in the mill, and from wheat rust.

Whereas reactions varying from a simple erythema to small wheals with small pseudopods and erythema were obtained with one or several of the fractions used, the gross reactions in every case were obtained first from extracts made up from dust escaping from the apparatus for the first cleaning of the grain and secondly from flour dust collected from localities in which this type of wheat dust was most abundant. The latter dust appeared macroscopically to be made up entirely of wheat flour. The former appeared microscopically to be made up of about equal quantities of hairs and the surface scales from wheat. It was difficult to separate these two elements, so that tests were made from the mixture of the two. Scratch tests made with the bran and germ fractions gave much smaller reactions than tests with hairs, and tests with the better grades of flour gave little or no reaction.

Fig 2—Specimen of dust taken from the first cleaning of wheat grains in the process of milling with a human hair placed laterally in the dust. Note by comparison with the human hair how small and sharp are the hairs of wheat grains. An extract of this fraction of the grain gave very much larger skin tests in millers with asthma than did extracts of other portions of the grain such as bran germ and the various grades of flour. Injection of infinitesimal amounts of wheat hair extract gave large local reactions and asthma in sensitive millers. The hairs of the wheat grain appear morphologically and chemically to be vicious sensitizers to workers in flour mills.

Intracutaneous tests with high dilutions of the hair and dust fractions would give rise to large wheals with pseudopods and large areas of erythema, and tests with high dilutions of extract given subcutaneously caused asthma.

TREATMENT

Two patients were treated with small ascending doses of wheat dust extract, with marked increase in their tolerance and gross symptomatic relief. However, after thorough trial these two patients became discouraged, in fact frightened into discontinuing their work as millers, because of severe attacks of asthma, which occasionally followed unavoidable gross exposure to the dust from wheat.

COMMENT

I once observed a case of iritis caused by hairs that had penetrated the cornea and lodged in the iris. These hairs could be seen with a corneal microscope and were the same color as the hairs in a brush used by the patient in applying remedies

to the eye for conjunctivitis. The iritis was looked on as a foreign body reaction.

If one will observe the small size of wheat hairs as compared with human hair, shown in figure 2, one should be convinced that these hairs might penetrate delicate structures in the respiratory tract and no doubt cause foreign body reactions as well as sensitize susceptible individuals.

It is believed that the asthma observed in the millers is of two sources, one a foreign body reaction, the other an allergy reaction caused by sensitization to some substance contained in the wheat hair or carried into the tissues by the wheat hairs.

The cases of asthma referred to in this paper were unusually severe, prolonged and intractable. It is believed that this is due to the twofold source of asthmatic symptoms, namely, the foreign body reaction and the allergy reaction.

CONCLUSIONS

From experience gained from a study of four consecutive cases of asthma among wheat flour mill workers, sensitization to the hairs and outer cells of wheat proved to be the commonest cause of asthmatic symptoms.

Avoidance of wheat hairs gave relief in each case.

Continuous exposure to wheat hairs over a period of years caused debility and emphysema.

Treatment with extract of wheat hairs is partly successful but does not protect the patient against extreme exposure to wheat dust. A change in occupation is often advisable unless wheat dust can be avoided.

PENTOSURIA IN TWINS

MORRIS ENKLEWITZ M.D. AND MARGARET LASKER M.S.
NEW YORK

This case is of interest for the following reasons: 1 It is the first recorded instance of pentosuria occurring in twins. 2 One of the twins is a physician. 3 Reducing substances in the urine have been known to be present for seventeen years. 4 The cases were previously reported as juvenile diabetes in twins¹ and as renal diabetes².

History—L. W., a man, aged 28, a physician, and M. W., his twin sister, came under observation in 1918, at the age of 11 years, because the girl complained of irritation of the genitalia and thirst. Examination of the urine revealed sugar at this time. Because the two children always suffered simultaneously from the same diseases, the mother had the boy's urine examined, and sugar was found in it also. Shortly thereafter the children were hospitalized for further study. The urine showed a reducing substance, which was analyzed and thought to be dextrose. The blood sugar of both children was 0.06 per cent. The diagnosis at this time was juvenile diabetes in twins. It was found that they were excreting from 1.5 to 3 Gm. of sugar daily, and this amount remained fairly constant, despite efforts to eliminate the sugar completely. After three months of dietary restriction the children rebelled and ate what they pleased, with the exception of sugar. The blood sugar was 0.08 per cent and there were no symptoms suggestive of diabetes. The children developed normally and two years later the mother reported that they were perfectly well, but the urine of both still contained sugar. The diagnosis at this time was renal diabetes.

In 1933 L. W. came to Montefiore Hospital as a member of the resident staff and, learning of our interest in the various urine sugars, he consulted us. The interval history was entirely uneventful, he and his sister had not adhered to any diet. Occasionally when troubled by his conscience or by the fear that true diabetes might develop he voluntarily omitted sweets, but a robust appetite soon reasserted itself. The urine always contained a trace of sugar, and the blood sugar was always within normal limits.

The reducing substance was found to be pentose. The sister's urine also contained pentose. Specimens from both parents and a brother were examined and found to be sugar free.

¹ Strouse, Solomon. *M. Clinics North America* 1: 1241 (March) 1918.
² Strouse, Solomon. *Renal Glycosuria Arch. Int. Med.* 26: 768 (Dec.) 1920.

The reducing substance in the urine did not ferment with yeast and gave a positive Bial's test. Benedict's solution was reduced within ten minutes at 55 C. On treatment with phenylhydrazine the characteristic pentosazone was formed. The melting point after purification was 160 C. Mixed with an equal quantity of *d*-xylosazone (prepared from *d*-xylose) and recrystallized from 95 per cent alcohol, the racemic xylosazone was formed and the melting point was elevated to 200 C. In this way the reducing substance was identified as *l*-xyloketose. In twenty-seven other cases of pentosuria that we have studied, the urine sugar has also been established as *l*-xyloketose.

COMMENT

Pentosuria and renal diabetes are similar in many respects and may easily be mistaken for each other. In both conditions sugar is found in all specimens of urine, and the blood sugar and sugar tolerance are normal. Neither condition produces symptoms, and the finding of sugar in the urine is often an accidental one. The diagnosis can be established only by chemical studies and identification of the reducing substance. By means of three simple tests it is possible to learn whether one is dealing with renal diabetes or pentosuria. In cases of renal diabetes the fermentation test is positive, Bial's test is negative and Benedict's solution is not reduced at 55 C within ten minutes. In pentosuria the fermentation test is negative, Bial's test is positive and Benedict's solution is reduced at 55 C within ten minutes, provided the urine pentose is *l*-xyloketose. If further identification is desired, the osazone should be prepared and identified by microscopic examination and determination of the melting point.

In our series we have encountered several cases that have been wrongly diagnosed as renal diabetes and we would emphasize that in all cases of renal diabetes in which the reducing substance has not been identified another examination should be made, for it is in this group that one is most apt to discover cases of pentosuria.

Montefiore Hospital

PARATHYROID EXTRACT AND VIOSTEROL TREATMENT OF RADIUM POISONING

LLOYD F. CRAVER, M.D., NEW YORK
Attending Physician, Memorial Hospital
AND

HERMAN SCHLUNDT, PH.D., COLUMBIA, MO.
Professor of Chemistry, University of Missouri

In 1929 Flinn and Seidlin¹ reported the results of treating three cases of radium poisoning in painters of luminous dials by injections of parathyroid extract-Collip over a period of seven weeks. Their report was remarkable in that it showed a loss in radioactivity of about 50 per cent. In 1931 Flinn² reported an increase in the elimination of radium from the human body when the patients were given viosterol for some time. A marked decrease in radioactivity was again observed. The decrease in radioactivity was measured directly on the living subjects with an electroscope by the gamma method or by testing the radon present in the expired air of the patients.

Our patients were four radioactive girls of the New Jersey radium patients who were placed under the supervision of a commission consisting of Dr. James Ewing, Dr. E. B. Krumbhaar, and Dr. Lloyd F. Craver.

METHOD OF TREATMENT

The patients were not hospitalized but the administration of the drugs and the diet of the patients were carefully controlled. Since control over one of the patients was not so good as we desired, radium determinations were not made on her excreta.

The treatment was based on the assumption that the administration of a diet low in calcium together with injections of parathyroid extract might favor mobilization not only of calcium but also of part of the radium deposit in the bones, and

possibly its excretion. Since these patients all showed rather pronounced structural changes in the bones, it was thought best not to continue this "radium and calcium mobilizing regimen" indefinitely but to provide rest periods of high calcium intake together with small doses of viosterol, which was believed to favor assimilation of calcium, in order to permit some repair. Accordingly it was decided to give periods of treatment as follows:

1. No treatment

2. Three weeks of low calcium diet. Injections of parathyroid extract every other day, beginning with 10 units and increasing to 50 units a day.

Radium Elimination—Total Per Day Expressed in Micrograms (10^{-12} Gm.)

	Period	Patient A	Patient B	Patient C
1	Nov 3-6 1930 no treatment	1 040	118	268
2	Nov 24-27 1930 low calcium diet + parathyroid extract	1 639	142	312
3	Dec 15-18 1930 high calcium diet + viosterol	895	190	375
4	Jan 5-8 1931 same as period 2	1,381	250	624*
5	Jan 26-29 1931 same as period 3	979	191	384

This patient refused further injections of parathyroid extract

3. Three weeks of high calcium diet, calcium lactate 20 grains (13 Gm.) three times a day, and viosterol from 5 to 10 drops three times a day.

4. Three weeks the same as period 2, the amount of parathyroid extract being increased to the maximum dose of 50 units more rapidly.

5. Three weeks the same as period 3

Five collections of stools and urine were made, a three days collection of such excrement being lumped in separate containers.³ The first collection was for three days preceding the beginning of the treatment. The four other collections were for the final three days of each treatment period, as enumerated.

RADIUM DETERMINATIONS

Each collection of feces was ashed and weighed. The radium determinations were made on aliquot parts of the residues, by the emanation method, the bisulphate fusion method,⁴ or solution in nitric acid,⁵ being employed. These determinations were all made in duplicate. The samples of urine were evaporated to dryness, ignited and weighed. One radium determination was made on each collection of urine. The radium content of the urine rarely exceeded 5 per cent of the total radium excreted.

The results of the radium determinations are given in very condensed form in the accompanying table.

In February 1929⁶ patient A excreted a total of 1,115 micrograms ($1,115 \times 10^{-12}$ Gm.) radium per day; patient B, 322 micrograms.

In March 1931 Dr. Failla measured the radon expired by patient A. A decrease in activity of less than 10 per cent was observed.

In June 1932 a gamma ray measurement was made on patient A. The readings of the instrument came out practically the same as the value found in February 1929. Further examination of the patients for radioactivity following the experimental period was not found practicable.

COMMENT

The table clearly shows that the three patients responded only slightly to the administration of parathyroid extract with low calcium diet in their rate of elimination of radium, and the viosterol treatment with high calcium diet produced no increase. The increase observed for the parathyroid extract

3. Dr. W. D. Turner, Columbia University, in cooperation with the United States Radium Corporation, prepared the collection of excreta for the radium determinations. Dr. Henry C. Johnston of East Orange, N. J., supervised the details of medication and collection of excreta.

and low calcium intake, however, does not represent a substantial loss of radium. A simple computation will reveal this fact. If patient A eliminated radium at the increased rate of 1,640 micrograms daily for a period of three months, she would lose only 0.15 microgram of radium during this period. Since her radium content was about 20 micrograms, it will be noted that with her best record it would take a year and eight months to eliminate 1 microgram of radium, representing merely 5 per cent of the total radium in her system. Normally patient A eliminated about 3 per cent of the radium in her system in the period of a year and eight months. In other words, patient A who had contracted radium poisoning fully eight years before, retained the radium tenaciously. The administration of neither parathyroid extract nor viosterol caused a substantial reduction in the total radium fixed in the system.

THE RELATIONSHIP OF DRUG THERAPY TO AGRANULOCYTOSIS

CLINICAL LECTURE AT ATLANTIC CITY SESSION

ROY R. KRACKE, MD
AND
FRANCIS P. PARKER, MD
EMORY UNIVERSITY, GA.

Since the disease agranulocytosis, or acute granulopenia, was first described in Germany¹ in 1922 and in the United States² in 1924 there has been much study concerning its pathogenicity and, in particular its etiology. Since it was first described thirteen years ago there have been hundreds of reports of the disease in the medical literature and it was responsible for more than 1,500 deaths in the United States alone in the three year period ended in 1934.

There has been considerable discussion as to the occurrence of the disease before 1922, and this question is important because of the possible relation to various etiologic factors. It seems obvious that this disease is one that presents little diagnostic difficulty, since the clinical picture is dramatic, the outcome is usually fatal, and the physician who makes leukocyte counts should experience little difficulty in its recognition. It appears unlikely, therefore, that it occurred in any considerable numbers before the year 1922, for, if it had, expert clinicians of the preceding period would certainly have described it. Occasional instances of profound leukopenia, however, are recorded in the literature, such as the one reported by Brown³ in 1902, but these were only rare and sporadic as compared with the prevalence of the disease today.

We⁴ have pointed out in previous publications that the disease in the United States has occurred mainly in women of middle age, although no age is exempt, and that it occurs rarely in the colored race except in those instances in which a definite etiology, such as the administration of neoarsphenamine, can usually be

established. Also we have called attention to the fact that it seems to be more prevalent in people of a better social status, and this is further indicated by its rarity in municipal and charity hospitals. When such cases do occur, the history of drug administration can usually be elicited. In addition, we have noted the prevalence of the disease among people of the medical group and our studies show its frequency in this group to be eight times that of the population of the United States at large.^{4b}

Agranulocytosis seems to be world wide in its distribution and has been reported mainly from the so-called civilized countries. However, this might be explained on the basis of better facilities for diagnosis and reports. By far the largest number of cases apparently have occurred in the United States and Germany, while they have been fairly numerous in France and Italy but comparatively rare in Great Britain, where, according to Hall,⁵ only twelve cases have been observed. It seems to occur in larger numbers in those countries which have become flooded with various synthetic drugs.

CHARACTERISTICS OF THE DISEASE

Agranulocytosis may be defined as a disease in which, essentially, there is a marked diminution, or total absence, of the granulocytes of the peripheral blood, which is followed by loss of cellular resistance and this, in turn, followed by infectious processes of various types. Although the basic pathologic change is a neutropenia of the peripheral blood the underlying pathologic process in the bone marrow has not been completely worked out. It seems, however, that there is a hypoplasia of granulocytic elements in the bone marrow and it is our purpose in this paper to determine from available evidence whether or not these changes are caused by the use of certain drugs.

ETIOLOGY

Since the disease was first described, many efforts have been made to determine its cause. Among the first workers in this field were those who endeavored to establish a bacterial etiology, including Lovett,⁶ working with *Bacillus pyocyaneus* and, more recently, Dennis,⁷ who attempted to show that the absorbed toxins from growing bacteria were capable of producing a profound leukopenia. Many efforts have been made to produce the disease in lower animals by the injection of any and all bacteria that have been isolated from the blood streams of various patients, but all of these have been generally unsuccessful and the degree of leukopenia produced by the injection of this class of products seems to be no different than that produced by the injection of any finely divided, inert, particulate matter.

Other theories of etiology have included one of dietary deficiency, as illustrated by the work of Langston and Day,⁸ who have been able to produce marked leukopenia in monkeys by the use of diets deficient in vitamin G. However, their animals showed red cell and platelet deficiencies as well, resulting in a hematologic picture more nearly simulating aplastic anemia. Furthermore, Miller and Rhoads⁹ have produced similar

leukopenias with ulcerative stomatitis by feeding dogs a type of deficiency diet that causes black tongue. It is possible that these dietary deficiencies may play some role in the experimental production and clinical development of the leukopenic state.

Another conception of the cause of agranulocytosis is that which assumes a hormonal dysfunction and in support of this is the work of Britton and Corey⁹ who observed marked leukopenia in their groups of adrenalectomized cats. Also Thompson¹⁰ has stressed the coincidental occurrence of menstruation in his cases of agranulocytosis and states that in eighteen young women with agranulocytic angina the onset of subjective symptoms occurred within a day or two of the onset of the regular menstrual period and that all were menstruating at the time of admission to the hospital. At first this appeared to be an important incrimination of hormonal disturbances in the production of the disease, but it was realized that young women with painful menstruation usually take various types of analgesics at that time, and this class of patients can now be explained on the basis of drug administration prior to and during the menstrual period. In this connection, Johnson¹¹ has reported the case of a doctor's wife who suffered recurrent attacks of agranulocytosis coincident with menstruation, which at first was thought to be etiologic in producing her attacks, but when she discontinued the use of cibalgin (containing amidopyrine), there were no further recurrences.

The experimental production and clinical development of various types of granulopenia, after contact with certain chemicals, has long been recognized. In 1910 Selling¹² made a careful study of three cases of profound leukopenia with hemorrhages that occurred as a result of the cumulative and delayed effect of industrial benzene poisoning, and since that time many observations have been made relative to the depressant action of benzene on the leukopoietic system. Weiskotten¹³ has demonstrated the marked depressant effect of benzene on the hematopoietic system of rabbits and one of us¹⁴ has shown that benzene can be injected into rabbits in such small quantities as to exert a selective action on the leukopoietic system producing a profound leukopenia with the red cells and platelets unaffected. So far as is known at this time, benzene is the only chemical that will consistently produce a profound leukopenic state in an experimental animal.

RELATION OF DRUGS TO LEUKOPENIA

The first intimation that drugs might be responsible for agranulocytosis was a publication¹⁵ in September 1931 describing a case of acute fulminant agranulocytosis following the ingestion of large quantities of acetphenetidin. Also in January 1932 it was reported¹⁶ that eight of a series of nine patients had taken drugs of the coal-tar series prior to the clinical onset of their disease, and at that time unsuccessful efforts were

reported to produce the disease in rabbits by the injection of amidopyrine, acetphenetidin, Peralga and Dial. In May 1933 Videbech¹⁶ of Denmark reported a typical case following the administration of amidopyrine. This was followed by two cases reported by Costen,¹⁷ one following amidopyrine and the other acetphenetidin. In 1933 deVries¹⁸ reported from Holland one case following the administration of amidopyrine. These reports were then followed by that of Madison and Squier¹⁹ in which they pointed out that all fourteen of their patients had developed the disease after the use of amidopyrine or one of its combinations. Following their report, Watkins²⁰ restudied the cases of agranulocytosis seen at the Mayo Clinic and found that thirteen of these had apparently followed the administration of amidopyrine. Then Holten, Nielsen and Transbøl²¹ in Denmark reported that five cases of agranulocytosis had developed following amidopyrine medication while the patients were being hospitalized for other diseases. At the same time Jorgensen²² reported another case from Denmark, after amidopyrine. There then followed rapidly an increasing number of reports of patients developing the disease following the use of amidopyrine particularly and involving some other drugs as well. These include one case by Andersen,²³ another by Holten, Nielsen and Transbøl,²⁴ fifteen by Seemann,²⁵ one by Larsen,²⁶ one by Randall,²⁷ fourteen by Hoffman, Butt and Hickey,²⁸ two by Zininger,²⁹ four additional cases by us,³⁰ one by Zinberg, Katzenstein and Wice,³¹ two by Rawls,³² one by Benjamin and Biederman,³³ one following dinitrophenol by Bohn,³⁴ then eighteen by Groen and Gelderman³⁵ from Holland, two by Corelli³⁶ from Italy, one after dinitrophenol by Davidson and Shapiro,³⁷ seventeen by Fitzhugh,³⁸

six by Plum³⁸ from Denmark, one by Witt,³⁹ who also observed two others following amidopyrine, one by Knudsen⁴⁰ from Denmark, two following dinitrophenol by Dameshek and Gargill,⁴¹ another after dinitrophenol by Silver,⁴² seven by Jackson,⁴³ one by Johnson⁴⁴ another by Holten, Nielsen and Transbøl⁴⁵ one by Moltke⁴⁶ of Denmark, and then four from China by Zia and Forkner⁴⁷ in patients who were being treated for kala-azar with Neostibosan. Then Squier and Madison⁴⁸ reported six additional cases, one presumably following acetanilid, and this was followed by one from England by Fisher,⁴⁹ another English case by Smith,⁵⁰ one by Stone and Margolis,⁵¹ then one from England by Hall,⁵² and in the meantime Sturgis⁵³ had found that seven of the nine cases seen at the University of Michigan had followed the administration of amidopyrine. Then an additional one was reported by Plum⁵⁴ from Denmark, followed by one by Maarsso⁵⁵ of the same country. Finally, another after amidopyrine was reported by Taussig⁵⁶ and another by Limarzi and Murphy⁵⁷ in May 1935. This long list of reported cases of agranulocytosis apparently following the administration of drugs may not be entirely complete, but we find no reference to any others in the literature available to us.

Thus there have been reported at this time 172 cases of agranulocytosis that apparently have followed the administration of drugs. Of this group 153 followed the use of amidopyrine, six dinitrophenol, four Neostibosan, three acetphenetidin, two acetanilid, two antipyrine, one acetylsalicylic acid and one quinine. It can be readily seen, therefore, that the chief indictment of drugs in the production of this disease is against amidopyrine, either alone or in combination with one of the barbiturates, and it appears that there can be little question that amidopyrine is causative in a large number of cases. It also seems that the evidence incriminating dinitrophenol is quite definite. It is questionable as to whether acetanilid, acetphenetidin antipyrine, acetylsalicylic acid and quinine are capable of producing the disease.

It has long been recognized that organic arsenical compounds are capable of producing profound leuko-

cytic depression and, in some instances complete bone marrow aplasia, and there are many reports of agranulocytosis following the administration of neoarsphenamine, such as those by Cassoute, Poinso, Zuccoli, Montus and Guerard⁵⁸ and by Pouzin-Malegue.⁵⁹ Also it has been shown by Mink and Campbell,⁶⁰ in a careful study of reactions following the administration of neoarsphenamine in the United States Navy over a period of five years, that definite bone marrow depression occurs in a small percentage of the cases, with leukopenia being a predominant part of the hematologic picture. It should be pointed out here that the organic arsenical products are composed mainly of a double benzene ring structure.

Also there have been reported numerous instances of agranulocytosis and the granulopenic syndromes following the injection of the gold salts, which are widely used in the treatment of tuberculosis and arthritis in France. At least twelve of these have been reported by Lande,⁶¹ Jacob and Douady,⁶² Achard, Coste and Cahen,⁶³ Jacquelin and Allanic,⁶⁴ Brailion,⁶⁵ Angeras and Ginsbourg,⁶⁶ Chabaud, Ginsbourg and Langlet,⁶⁷ Flandin, Escalier, Sassier and Joly,⁶⁸ and Forestier.⁶⁹ Ten of the twelve patients were treated with crisalbine, which is a straight chain organic gold compound, while two were treated with solganol, which contains a benzene ring structure. It should be pointed out that all these patients were being treated for either tuberculosis or arthritis and apparently no effort was made to ascertain whether or not there was coincidental administration of amidopyrine or some of its preparations. Forestier⁶⁹ states that the administration of these analgesic preparations could not be excluded in his two patients. Thus, in a summary of the cases of agranulocytosis reported as having followed the administration of drugs, it seems that at least four definite classes of drugs can be incriminated: amidopyrine, dinitrophenol, gold salts and organic arsenical compounds.

In addition to the large number of patients that apparently have developed the disease following the administration of drugs, much clinical experimental evidence has accumulated to indicate that drugs are causative in agranulocytosis. For example, Madison and Squier¹⁹ gave a single dose of amidopyrine to each of two patients who had recovered from the disease and this was followed by a profound fall in the granulocytes, with a recurrent attack. They also gave a normal person a similar dose, with no change in the

leukocyte count. Furthermore, the administration of amytal alone, a straight chain barbiturate, produced no effect on the blood counts of the patients who had recovered. Plum²⁹ studied the effect of a single dose of amidopyrine on a patient who had recovered from agranulocytosis, by giving only 3 grains (0.2 Gm.), this resulting in the leukocyte count falling from 9,000 to 1,900 in one and a half hours, and at the end of twenty-four hours the count was 2,000 per cubic millimeter. He concluded that a small, single dose of the drug has a marked depressant effect on the white cell count. Sturges⁶¹ gave amidopyrine in doses varying from 5 to 15 grains (0.3 to 1 Gm.) to three patients who had recovered from the disease and this was followed by a profound reduction in the leukocyte count, but the administration of 5 grains of barbitol had no effect. Benjamin and Biederman³² gave 10 grains (0.65 Gm.) of amidopyrine to a patient who had recovered, producing a leukopenia of 1,000 per cubic millimeter, twenty-four hours later. The same patient was then given acetylsalicylic acid and a barbiturate with no effect. In the series of Rawls,³¹ of 200 patients being treated for arthritis with amidopyrine, two developed neutropenia and one of these recovered by simply leaving off the drug, but when it was resumed, a second attack was precipitated. Zinberg, Katzenstein and Wice³⁰ gave 5 grains of amidopyrine to a patient who had recovered, which was followed by a leukopenia of 2,700. Two weeks later the same patient was given another dose of 5 grains with a resulting leukopenia of 1,300. Therefore it can readily be seen from such experiments as these that certain individuals, especially those who have recovered from an attack of the disease, seem to be unusually susceptible to the action of the drug, to such an extent that successive attacks may be produced at will, but that this cannot be done in a person who is not susceptible. It does not necessarily follow that all cases of agranulocytosis would react in this way, as indicated by the observation of Limarzi and Murphy,⁵⁵ who treated a patient with a large quantity of amidopyrine, apparently followed by no ill effects. Terry and Sanders⁶⁸ have even treated a patient with myeloid leukemia by daily administration of amidopyrine and reported a reduction of the leukocyte count from 180,000 to 20,000 per cubic millimeter, although previous radiation therapy might have been responsible for this.

When the relationship of drug administration to agranulocytosis was first suspected, there soon followed attempts on the part of many investigators to reproduce the disease in lower animals by the administration of the drugs in question. One of us¹⁴ reported the injection of rabbits with amidopyrine, acetphenetidin, Peralga and Dial, but with no effect on the leukocyte count in any of the animals. Madison and Squier¹⁹ administered amidopyrine in large doses to rabbits by mouth and produced a leukopenia on the thirtieth day in only one animal out of eighteen. Hoffman, Butt and Hickey²⁸ stated that they fed amidopyrine to a number of rabbits and that this was followed in a few weeks by a definite depression of the total white cell count. Feeling that the Neostibosan used in the treatment of kala-azar might have been responsible for their four cases of agranulocytosis, Zia and Forkner⁴⁰ gave animals large and repeated doses of the drug and stated that they could observe no significant changes in the blood picture.

In previous studies we⁴⁴ have shown that when benzene is injected into rabbits the effect on the bone marrow is probably produced by one of the oxidation products, and we have found that marked leukopenia could be produced by catechol and quinone^{4b} but that no depressant effect was observed from the other oxidation products. Also we have demonstrated that amidopyrine can be oxidized easily, in vitro, under

conditions simulating those in the gastro-intestinal tract, and that the resulting product contains catechol and quinone. Chimenko,⁶⁹ working with rabbits, found that the injection of quinone, catechol, dinitrophenol, antipyrine and phenylhydrazine would prevent the response of leukocytosis that normally follows the administration of nucleic acid products. He concluded, therefore, that the activity of the bone marrow of these

animals was inhibited by these chemicals. Miller⁷⁰ gave amidopyrine orally to a group of sixteen dogs and found that the drug exerted a toxic effect on the bone marrow, but apparently insufficient to produce depression of the circulating elements of the blood. It can be seen, therefore, that experimental leukopenia in animals can be produced occasionally by the oral administration of drugs, with moderate frequency with their oxidation products, and consistently with benzene. It seems probable that another factor is necessary in the development of agranulocytosis in either the animal or man, and this factor may be that which is referred to as hypersensitivity, susceptibility, allergy or idiosyncrasy.

THE MECHANISM OF DRUG ACTION

Allergic reactions to drugs have long been recognized, but descriptions of this phenomenon have not included bone marrow or blood cellular changes. Unger⁷¹ states that the coal-tar series of drugs are more important than any others from the point of view of allergy. Taussig⁷⁴ has reported an instance in which the patient used amidopyrine for many years with impunity, but after abstaining from the drug for several months he had a single dose of 5 grains, and this was followed immediately by a severe attack of urticaria, angioneurotic edema, bronchial asthma and a mild granulopenia which lasted for several days. Squier and Madison⁴⁷ were able to demonstrate skin sensitivity to amidopyrine by patch testing in two of three patients who had recovered. They believe that acute granulocytopenia can be produced by repeated administration of amidopyrine to persons who have developed an allergic hypersensitivity to that drug. Groen and Gelderman³⁴ believe that certain individuals have an increased susceptibility or an idiosyncrasy to amidopyrine. Randall²⁷ studied the allergic response in his patient by injecting amidopyrine and phenobarbital subcutaneously, but this was not followed by a local reaction or change in the leukocyte count. Benjamin and Biederman³² found no evidence of the allergic state in their patient with studies by intracutaneous and patch test methods. Limarzi and Murphy⁶⁶ also did patch tests on their patient, with negative results. Reznikoff⁷² states that, when one considers the enormous amount of amidopyrine consumed and the relatively few individuals affected with granulocytopenia, it is obvious that one is dealing with the question of sensitivity in certain patients rather than with the universal action of the drug. Vaughn⁷³ has pointed out that a leukopenia will usually be found after ingestion of food to which a patient is sensitive, but, on the other hand, he emphasizes that the leukopenia involves all white blood cells and is not a true granulopenia.

It can be seen, therefore, that sufficient evidence has not accumulated to justify the statement that the action of amidopyrine is a true allergic response. It appears more probable that other factors influencing the fate and disposal of drugs in the animal body have not been worked out sufficiently to explain why the occasional person has a damaged hematopoietic system from the use of drugs.

We have presented evidence in previous publications⁴ to indicate that in certain individuals amidopyrine may undergo an atypical oxidation reaction and that certain of these oxidation products have a depressing effect on the bone marrow and are capable of producing granulopenia in rabbits. This action brings up the question as to what part of the amidopyrine structure is responsible for its depressant effect. Herz⁷⁴ attributes the action to the attached pyrazolon group, mainly because this structure is found only in amidopyrine, and also because of its chemical similarity to phenylhydrazine, which is a recognized erythropoietic depressant. Andersen²³ also believes that it is the pyrazolon group which is the harmful element and not the benzene nucleus. On the other hand, there is more evidence to indicate that the bone marrow depression is caused by those products containing the benzene ring in such a form that they lend themselves to easy oxidation, and we have pointed out before that the benzene ring with either the attached amine or nitro group fulfills this requirement. We consider the ease of oxidation of the drug to be the most important factor and we are cognizant of the fact that many other drugs, such as acetylsalicylic acid, contain the benzene ring, but they do not oxidize readily and therefore are relatively harmless from a hematologic point of view. Furthermore, the occurrence of a group of cases following the administration of dinitrophenol is strongly indicative that the pyrazolon ring plays no part in the production of this disease.

Assuming that these drugs are capable of producing agranulocytosis in susceptible individuals, the question arises as to how much of the drug is capable of producing an attack. There can be no answer to this question, since the case reports show that an attack may be precipitated in one person by the administration of a single small dose, whereas in another it appears to result from the administration of large quantities over a long period of time.

Watkins²⁰ reviewed a series of thirty-two patients with granulocytopenia who had been seen at the Mayo Clinic and found that twelve of these had taken amidopyrine before the clinical onset, that twelve others had taken only the barbiturates, and that in eight patients no drug had been used before the onset of the illness. This was the first, and practically the only report, incriminating the barbiturates and it would appear more likely that thorough and adequate histories could not be obtained on this group. There has been little evidence to justify the inclusion of the barbiturates among the drugs causing agranulocytosis.

It should be emphasized that it is practically impossible to obtain a reliable drug history on a patient who is dead, regardless of all statements of relatives, friends and physicians, concerning medication in that patient. Since the drug theory of etiology has become wide spread, Fitzhugh³⁷ has reviewed a series of patients and his report indicates that only a small percentage in the group followed the use of amidopyrine, but a negative history of drug usage has little value. We have attempted to obtain information from patients, with absolute denial of their having taken amidopyrine drugs, and in one instance found that the patient unknowingly had been taking large quantities of amidopyrine in a patented preparation, and this was ascertained only after chemical analysis of the product. In another instance we had to search through thousands

of old prescriptions in a drug store to establish the fact that the patient had been taking amidopyrine. Patient 1 in Plum's²⁸ series was a woman who denied taking amidopyrine or any of its compounds, the patient's physician also stating that it could be absolutely excluded, and it was only after the most thorough investigation that this history was found to be unreliable. Another patient in Plum's series stated that she absolutely had not taken any amidopyrine preparations. In this her physician also agreed, and it was only on examination of her medicine chest that amidopyrine preparations, which she had been using, were found. Zimniger²⁹ lived in the same house with and prescribed for her two aunts, who both died from agranu-

locytosis. After their death she was amazed to find many empty containers of amytal compound in their apartment. These examples illustrate the difficulty of procuring a reliable history in a living patient and it should be emphasized that a negative drug history is often a worthless one. Therefore, any large series of cases reinvestigated for history of drug administration such as those reported by Jackson,⁴³ Fitzhugh⁴⁷ and Watkins,⁴⁹ are relatively unreliable.

Furthermore, since 1922, amidopyrine has been so widely used in combination with other preparations, such as the barbiturates, and the resulting mixtures have been given such a wide variety of names that it is practically impossible for either patient or physician to be aware of what drugs do or do not contain amidopyrine. A list of some of the proprietary preparations that did, or do now, contain amidopyrine is given in table 2.

COMMENT AND RECOMMENDATIONS

At this time it seems well established that amidopyrine, dinitrophenol and possibly other closely related drugs are incriminated as etiologic agents in agranulocytosis. Evidence to this effect is found in the widespread introduction of these drugs coincident with the appearance of the disease, in the occurrence of 172 cases that have been reported as following the use of these drugs, in the occasional patient who has recovered only to develop successive attacks on the readministration of the drugs, in the occasional experimental animal that has developed the disease after the introduction of the drugs or some of their oxidation products, and finally in the prevalence of the disease in that class of people who are the largest users of these drugs.

This conception of the etiology has received general confirmation throughout the world, as indicated by the reports of Plum⁵² from Denmark, Groen and Gelderman⁵⁴ from Holland, Corelli⁵⁵ from Italy, Smith,⁴⁰ Fisher⁴⁸ and Hall⁵ from England, and those of Sturges⁵¹ and many others from the United States. Johns⁷⁵ states that he has seen ten cases of this disease, in all of which a history of drug administration could be elicited. Groen and Gelderman⁵⁴ conclude that a drug etiology of agranulocytosis is much more often the rule than the exception. Plum⁵² states that since the etiologic significance of amidopyrine has become a subject of general discussion in Denmark no new patient with agranulocytosis has been admitted to the Blegdams Hospital during a five months period, whereas in the same five months in the preceding year five patients were seen with the disease. We are impressed with the decreased number of cases in Georgia since knowledge of this relationship of drugs has become widespread among physicians and the public.

The question now arises as to what should be the attitude of the physician with respect to these drugs, particularly amidopyrine. The Council on Pharmacy and Chemistry of the American Medical Association,⁷² in its recommendations concerning this question, discourages the indiscriminate administration of amidopyrine and, in particular, the exploitation of this drug to the public, in which individuals are urged to resort to self medication, and it condemns the situation whereby a potentially harmful drug is exploited to the public under a hundred different uninformative trade names. It seems desirable that it should be dispensed only by physicians in nonrefillable prescriptions, so that this danger of agranulocytosis may be largely removed from the unprotected public. Furthermore, it seems that every physician should prescribe amidopyrine with caution and he should not follow the careless custom of giving a patient a prescription for relief of pain with such indefinite direction as to have it refilled whenever the patient chooses to do so.

Amidopyrine is admittedly a valuable drug and, no doubt, has its place in therapeutics, but only under well controlled conditions and under supervision of a physician, and even then the leukocyte count should be checked from time to time to determine whether or not there is bone marrow depression.

A discussion of the relationship between drug administration and agranulocytosis would be incomplete without some comment relative to drug therapy after the disease has developed. It seems to us that the most valuable therapeutic measure that can be employed is to refrain carefully from using amidopyrine drugs dur-

75 Johns, F M. Personal communication to the authors Dec. 17 1934.

ing the attack, and it seems probable that the recovery of a patient is sometimes due to the mere omission of the offending drug, and it is in such instances that some supposedly remedial agent is often erroneously credited with a therapeutic efficacy that it does not deserve. If physicians would use these drugs with caution, if their indiscriminate sale could be controlled, and if the distribution of patented preparations containing amidopyrine could be suppressed, it is possible that this disease, which has now claimed thousands of lives, might entirely disappear.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary

COD LIVER OIL CONCENTRATE LIQUID (LEDERLE)—A concentrate of the unsaponifiable fraction of cod liver oil dissolved in sufficient cod liver oil to give the desired potency to the marketed product. It has a vitamin A potency of not less than 55,100 units (U S P X Revised, 1934) per gram and a vitamin D potency of not less than 5,510 units (U S P X Revised, 1934) per gram.

Actions and Uses—It possesses the therapeutic properties attributed to the vitamins present in cod liver oil.

Dosage—For the concentrate in vials, 9 drops (3 minims, 0.18 cc) daily for infants (the vials are marketed with a dropper designed to dispense three drops to the minim), for the capsules, one to two daily for children, two to three daily for adults.

Manufactured by the Lederle Laboratories Inc. Pearl River, New York. No U S Patent or trademark.

Cod Liver Oil Concentrate Liquid (Lederle) Vials, 5 cc—Each minim (3 drops, 0.06 cc) has a vitamin A potency of not less than 3,138 units (U S P X Revised, 1934) and a vitamin D potency of not less than 314 units (U S P X Revised, 1934).

Cod Liver Oil Concentrate Liquid (Lederle) Capsules, 3 minims—Each capsule has a vitamin A potency of 9,400 units (U S P X Revised, 1934) and a vitamin D potency of 940 units (U S P X Revised, 1934).

LAROCAINE HYDROCHLORIDE—*p*-aminobenzoyl-2,2-dimethyl-3-diethylaminopropanol hydrochloride.— γ -diethylamino- β -dimethylpropyl-*p*-aminobenzoate hydrochloride— $\text{NH}_2(\text{C}_6\text{H}_4)\text{OCH}_2\text{C}(\text{CH}_3)_2\text{CH}_2\text{N}(\text{C}_2\text{H}_5)_2 \text{HCl}$. The base of larocaine belongs to the procaine type. It differs from procaine in having a propanol group instead of the ethanol group and has two methyl groups attached to the former.

Action and Uses—Larocaine hydrochloride acts as a surface as well as a conduction (infiltration) anesthetic and compares quite favorably in both fields with either cocaine or procaine. Larocaine hydrochloride is quick in action and produces anesthesia of a somewhat longer duration than cocaine or procaine. The average duration of conduction anesthesia is from three to five hours. Larocaine hydrochloride is non-narcotic and non-habit forming.

Dosage—For corneal and conjunctival anesthesia, from 2 to 5 per cent solutions may be used. In otorhinolaryngology, 5 to 10 per cent solutions have been employed. From 0.75 to 1 per cent solutions are used in urology. For conduction anesthesia, 0.25 to 2 per cent solutions may be used. Solutions of larocaine hydrochloride may be sterilized by boiling for ten minutes. Epinephrine when desired may be added just prior to administration. Stock solutions should be kept in dark bottles. The product is supplied in vials containing $\frac{1}{8}$, $\frac{1}{4}$, $\frac{1}{2}$ and 1 ounce of larocaine hydrochloride in powder form.

Manufactured by F. Hoffmann-La Roche & Co. Basle, Switzerland (Hoffmann-La Roche Inc. Nutley, N. J. distributor). U S Patent 1,824,676 (Sept. 22, 1931; expires 1948). U S trademark 283,775.

Larocaine hydrochloride occurs as a fine white odorless crystalline powder when applied to the tongue it possesses a bitter taste followed by a sense of numbness permanent in the air at ordinary temperatures freely soluble in water soluble in alcohol sparingly soluble in chloroform insoluble in ether. Its aqueous solution is faintly acid to litmus. Larocaine hydrochloride melts at 196-197°C, with decom-

position. From aqueous solutions, alkali carbonates and hydroxides precipitate the free base as a colorless oil which solidifies after a time at ordinary temperature.

Dissolve about 0.05 Gm. of larocaine hydrochloride in 50 cc. of water separate portions of 5 cc. each to one portion add 5 cc. of silver nitrate solution a white precipitate results soluble in an excess of ammonia water to another portion add 0.2 cc. of diluted hydrochloric acid 0.2 cc. of a 10 per cent solution of sodium nitrite and gradually mix with a solution containing 0.2 Gm. of betanaphthol dissolved in 10 cc. of a 10 per cent sodium hydroxide solution a red precipitate is formed (distinction from the anesthetics not responding to the diazo reaction) to another portion add 0.3 cc. of diluted sulphuric acid followed by the addition of 0.5 cc. of tenth normal potassium permanganate solution the red coloration disappears immediately (distinction from cocaine and some other local anesthetics). Dissolve about 0.1 Gm. of larocaine hydrochloride in 1 cc. of sulphuric acid the solution is colorless (readily carbonizable substances). Saturate about 0.1 Gm. of larocaine hydrochloride dissolved in 10 cc. of water with hydrogen sulphide no coloration or precipitation results (sells of heavy metals).

Dry about 0.5 Gm. of larocaine hydrochloride accurately weighed, at 100°C. for six hours the loss in weight does not exceed 1 per cent. Incinerate about 0.5 Gm. of larocaine hydrochloride, accurately weighed, the residue is not more than 0.1 per cent. Transfer about 0.3 Gm. of larocaine hydrochloride accurately weighed to a 500 cc. Kjeldahl flask and determine the nitrogen content according to the official method described in Official and Tentative Methods of Analysis of the Association of Official Agricultural Chemists, third edition page 20 chapter 2 paragraph 22 the percentage of nitrogen corresponds to not less than 8.8 per cent nor more than 9 per cent when calculated to the dried substance. Transfer about 0.3 Gm. of larocaine hydrochloride accurately weighed to a suitable Squibb separatory funnel, add 25 cc. of water followed by the addition of 5 cc. of ammonia water extract with seven successive portions of ether using 35 cc., 30 cc., 25 cc., 25 cc., 20 cc., 15 cc. and 10 cc. respectively wash the combined ethereal solution with 15 cc. of water filter through a pledget of cotton and evaporate to a thick oil in a stream of warm air expose over sulphuric acid in a partially exhausted desiccator dissolve the only residue in about 20 cc. of previously neutralized alcohol warm slightly add 12.5 cc. of tenth normal hydrochloric acid solution followed by the addition of an equal volume of water determine the excess of acid by titration with tenth normal sodium hydroxide solution using methyl red as an indicator the amount of tenth normal hydrochloric acid solution consumed corresponds to not less than 87 per cent nor more than 89 per cent aminobenzoyldimethyldiethylammonio propanol when calculated to the dried substance. Transfer the ammoniacal aqueous portion from the immiscible solvent extraction to a 400 cc. beaker and place on the steam bath for three hours add 100 cc. of water followed by the addition of 10 cc. of nitric acid and 25 cc. of silver nitrate solution subsequently boil with continuous stirring and allow to cool in a dark place. Collect the precipitate of silver chloride on a Gooch crucible, wash with a diluted nitric acid and water followed by alcohol and ether finally dry to constant weight at 105°C. the amount of hydrogen chloride calculated from the silver chloride found corresponds to not less than 11.5 per cent nor more than 11.7 per cent when calculated to the dried substance.

WHITE'S COD LIVER OIL CONCENTRATE (LIQUID)—A concentrate of the unsaponifiable fraction of cod liver oil dissolved in sufficient cod liver oil to give the desired potency to the finished product. It has a vitamin A potency of not less than 60,000 units (U S P X Revised, 1934) per gram and a vitamin D potency of not less than 8,500 units (U S P X Revised, 1934) per gram.

Actions and Uses—It possesses properties similar to those of cod liver oil so far as these depend on the vitamin content of the latter.

Dosage—For the Liquid: Infants, from six to eight drops daily, children, two to four drops daily, adults four drops three times daily. The liquid is marketed with a dropper designed to supply $\frac{2}{3}$ minim (0.041 cc.) in each two drops. For the Capsules: Children, one capsule daily, adults, one to two capsules daily.

Manufactured by Health Products Corp. Newark, N. J. U S patent 1,984,858.

White's Cod Liver Oil Concentrate Capsules, 3 minims—Each capsule contains White's Cod Liver Oil Concentrate (Liquid) 3 minims and has a vitamin A potency of not less than 10,260 units (U S P X Revised, 1934) and a vitamin D potency of not less than 1,453 units (U S P X Revised, 1934).

White's Cod Liver Oil Concentrate Liquid Vials, 50 cc—Each $\frac{1}{2}$ minim (0.038 Gm.) has a vitamin A potency of not less than 2,280 units (U S P X Revised, 1934) and a vitamin D potency of not less than 323 units (U S P X Revised, 1934).

DEXTROSE (See New and Nonofficial Remedies, 1935, p. 280).

Wm. S. Merrell Co., Cincinnati.

Ampoules Solution Dextrose 50%, 20 cc Each cubic centimeter contains approximately 0.57 Gm. of anhydrous dextrose.

Ampoules Solution Dextrose 50%, 50 cc Each cubic centimeter contains approximately 0.57 Gm. of anhydrous dextrose.

DIPHThERIA TOXOID (See New and Nonofficial Remedies, 1935, p. 392).

Parke, Davis & Co., Detroit.

Diphtheria Toxoid—(See New and Nonofficial Remedies, 1935, p. 395). For determining sensitivity to the nonantigenic portion of diphtheria toxoid a diluted diphtheria toxoid is applied. This is marketed in packages of one 0.5 cc. vial and in packages of one 5 cc. vial containing diluted diphtheria toxoid sufficient for five and fifty reactions tests respectively.

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION, AND FOR GENERAL PROMULGATION TO THE PUBLIC THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION

RAYMOND HERTWIG Secretary

SPINTRATE TABLETS (CANDY COATED)

Distributor—M & R Dietetic Laboratories, Inc., Columbus, Ohio

Manufacturer—Spinach Products Company of South Carolina, Columbia, S C

Description—Candy-coated powdered spinach tablets The powdered spinach (Spinrate, THE JOURNAL, Aug 5, 1933, p 448) contains small quantities of agar, gelatin or acacia gum and stearic acid The candy coating is sugar colored with United States Department of Agriculture certified color

Manufacture—Powdered spinach is admixed with small quantities of agar, gelatin or acacia gum, and stearic acid to permit molding into tablets, which are coated with colored sugar Each tablet contains 0.4 Gm of powdered spinach and 0.2 Gm of sugar coating

JENNY LEE BRAND GENUINE EGG NOODLES MINNESOTA BRAND EGG NOODLES—BROAD, FINE OR CHOW MEIN STYLE, MEDIUM WIDE

Manufacturer—Minnesota Macaroni Company, St. Paul

Description—Egg noodles prepared from durum flour, egg yolk and water

Manufacture—Durum flour is moistened with water and mixed with a definite quantity of egg yolk. The dough is kneaded, rolled, cut into ribbons, dried as described for Minnesota Brand Amberrolls—Elbow Macaroni (THE JOURNAL, Aug 3, 1935, p 369) and packed.

DISEASE AND HISTORY

The reciprocal relations of disease and history not only provide food for philosophic speculation but offer much information worthy of study by the statesmen who direct the destiny of nations. The panorama produced by the effect of one on the other has been recently painted by Stewart.¹ He questions the historical justification of the relative amount of study devoted, for example, to Napoleon and to Pasteur or to Jenner. Which, he asks, more definitely made and molded history? One cannot question, he concludes, that disease and its gradual control are tremendously important molders of the history of mankind.

The first steps of the nomad in civilization, the gathering of houses into towns, doubtless trebled disease and cost innumerable lives. The principles of sanitation, though known to the ancient Hebrews, for centuries lagged far behind the advance in other lines of what we call civilization. Primitive communities were thus saved from extermination chiefly by their instinct for isolation. This fact has left primitive peoples relatively free from diseases and relatively immune to those which they did have. New diseases, however, brought to such groups have again and again practically annihilated whole populations. The introduction of a new relatively innocuous disease such as measles among the Boers resulted in the loss of one fifth of their numbers in concentration camps.

Travel, added to the concentration of peoples, ushered in a wider area for disease. The speed of travel closely paralleled the spread of disease and the march of civilization. In the second century A. D. it took plague forty years to reach China from the Red Sea. In the fall of 1888 an influenza epidemic was at Hong-kong, by the beginning of the next November it was in St. Petersburg. But for modern preventive medicine, disease would now travel as fast as the airplane.

The effect of pestilences on individual communities and countries is a phase of historical study still largely undisturbed. Bubonic plague alone in the ten years

that preceded 1907 carried off 6 millions in India. In 1910 was fatal to 46,000 in Manchuria and as late as 1923 killed a quarter of a million people, mostly in India. This was in modern times, but this destruction appears small in comparison with the havoc wrought by the Black Death. Villages and towns were left without inhabitants, in London 50,000 bodies were thrown into one burying ground, in a year in Europe 25 millions of people, half the population, died.

Such a convulsion must of necessity make history. That this resultant history is contradictory does not invalidate the thesis. The effect in England has been variously described. "Amid the general lamentation and woe the influence and authority of every law, human and divine, vanished." It paralyzed trade and industry, especially agriculture, but also paralyzed war and politics. "It detached people from the soil, drove them into the towns, increased urban population at the expense of rural, planted the germs of commerce and industry and began the expansion of England manifested in the time of Elizabeth." So with desolation came elbow room and opportunity.

The association between war and disease is as old as war itself. Sieges and campaigns have more often been decided by the race between pestilences in rival camps than by the force of arms. An invading army has brought pestilences that destroyed the invaders themselves first and sometimes the enemy. At other times the invaders acquired new diseases from the neutral or enemy countries through which they passed. "All that we gained in the end by engaging in the crusades," said Voltaire, "was the leprosy." As late as the Civil War, two Northern soldiers died of disease for every one who died by the weapons of the enemy. Such examples may be multiplied through all history.

These are examples of how disease has wrought history. The connection has always been close, not only in the lives of nations but also in the lives of individuals who make the history of nations. The gastric ulcer of a premier, the migraine of a foreign minister, the failing memory of a cabinet officer or the paranoia of a dictator may change in a brief period the economics, the history or the health of a nation.

THE GENESIS AND CONTROL OF EPIDEMICS

So long as human beings are gregarious and prefer to live in crowded communities, they must contend with epidemics. In some modern centers of civilization there has developed a false sense of security in this regard. An epidemic is a disease of the crowd and may flare up like a forest fire. Modern preventive medicine and interest in public health measures have accomplished miracles in controlling herd infections. Nevertheless, calamity always is possible. Witness the recent terrific epidemic of malaria in Ceylon, where an enormous mortality rate has been recorded in a disease the cause of which is known and for which specific treatment is

¹ Stewart D. A. Disease and History. Ann. M. Hist. 7: 351 (July) 1935.

available. The Chicago outbreak of amebiasis was significant. Consider the St. Louis epidemic of encephalitis and the recent outbreaks of poliomyelitis. Historically our concepts of epidemics may be grouped in two broad periods: (1) the descriptive period, when the natural history of epidemics was studied and correlated as to place, time and meteorological conditions, (2) the modern period, when the rise, subsidence and periodicity of epidemics is studied mathematically, graphically and even experimentally.

As Garrison¹ has indicated, the main protagonists of the former point of view were Hippocrates, Baillou and Sydenham. The modern theories have been expressed by Farr, Pearson, Ross, Greenwood and others. Sir Ronald Ross has classed epidemic diseases into (1) those of sluggish course and progression, such as leprosy or tuberculosis, (2) diseases of periodic recurrence, such as measles or scarlatina, (3) pandemic diseases, such as plague, cholera and influenza, which appear in full force at wide intervals of time. Gill², a modern epidemiologist, has attempted a rational explanation of the genesis of epidemics. He finds that all epidemics and pandemics, irrespective of their parasitic cause or mode of spread, exhibit characteristic features as concerns geographic distribution, periodicity, seasonal incidence, wave form, diffusibility, toxicity, and special incidence in certain age groups. Gill maintains that there has been no demonstration of an exaltation of virulence of specific parasites in association with the rise of an epidemic. He presents the "quantum theory" as an explanation of the genesis of epidemics. This theory postulates that all epidemic manifestations are the outcome of loss of equilibrium between the dose of toxin and the degree of resistance, or between "infection" and "immunity." The effect of the introduction of living pathogenic organisms into the human body may be determined not only by the quantity of infection (dose) but also by the size (mass) and resistance (relative immunity) of the host. Circumstances conducive to a sudden increase of the infection quantum play a predominant part in determining epidemic outbreaks. The quantum theory of Gill states that four factors are concerned in the origin of all epidemics: the reservoir, the parasite, the immunity, and the transmission factor. The actual occurrence of an epidemic is due to quantitative changes in equilibrium between "infection" and "immunity." This theory assumes the presence in all parasitic diseases of a reservoir of infection in which the specific parasite will be able to survive in a state of symbiosis with its host during periods adverse to its transmission. No instance is known of an epidemic disease in which either man or one of the lower animals does not constitute the reservoir. A given disease may be endemic in a community and at times epidemic. The disease may be considered hyper-

endemic, when infection and immunity are constant and high, or mildly endemic, when infection and immunity are constant and low. As concerns epidemicity there is first a preepidemic status, during which infection is long interrupted and immunity is absent. Then follows the epidemic status, when infection is constantly high and immunity is low. As mortality and morbidity subside, the postepidemic status is reached, when infection and immunity are both high. This is followed by the interepidemic status, characterized by intermittent infection in association with high herd immunity.

It is the duty of the epidemiologist to keep accurate records of the important herd diseases, chart their incidence and even attempt to predict their epidemic and pandemic occurrence under certain climatic, meteorological, social and economic conditions. However, the modern epidemiologist is not content with general biostatistical studies. He has begun to develop experimental epidemiology, a comparatively new science of extraordinary importance to the general health of communities and nations. Topley³ in 1919 was probably the first modern epidemiologist to study disease as a mass phenomenon under experimental conditions. These pioneer studies were followed by similar though independent investigations by Flexner,⁴ Amoss⁵ and Webster.⁶ Topley noted that breeds and individuals possess definite and different amounts of nonspecific inherited resistance to infection. This resistance is affected by environmental factors, such as season, diet and social and economic conditions, and may be supplemented by a specific acquired immunity. The amount of resistance present in individuals or populations at a given time determines the extent and severity of disease. Topley found that he could induce experimental epidemics in mice under two sets of conditions: (1) by administering to each individual of a previously unexposed community a certain dose of the specific organism by a natural port of entry or (2) by adding susceptible immigrants to already infected populations. He demonstrated that the repeated addition of normal individuals to mouse populations infected with *Pasteurella* is followed by recurring epidemic waves. Such experiments also afford an opportunity of analyzing the microbic and host factors under natural yet controlled conditions and of determining whether virulence actually varies during epidemics and whether epidemics terminate by the development of a specific immunity in the population. In these studies, bacterial strains from fatal cases manifested the same degree of virulence as similar strains from healthy carriers. This tends to prove Gill's contention that there is no noteworthy

exaltation of virulence under epidemic conditions. Further studies indicated that strains of bacteria recovered from a given population at various endemic and epidemic periods of spontaneous infection were of uniform virulence. Experimental epidemiology has apparently demonstrated that the virulence of a given bacterial strain, when analyzed under natural and under controlled conditions, is a relatively stable property. However, changes in dosage exerted a direct effect on mortality when virulence and resistance were constant. These results further tend to substantiate Gill's quantum theory as to the genesis of epidemics. Topley has demonstrated that an epidemic spreading slowly among an isolated herd will lead to a smaller total mortality than will another epidemic of the same disease that spreads rapidly within a short time of its onset. A herd among which an epidemic is spreading will approach extinction more rapidly if it is subjected to the immigration of susceptibles of the same species than if it is kept in isolation. In his experiments Topley found that a bacterial infection which tends to spread naturally may be maintained in an experimental herd for an indefinite period, provided the herd is replenished by immigration of susceptible animals even though the rate of immigration is very slow.

The movement of susceptible but uninfected individuals is one of the main factors determining the course and duration of the epidemic spread of bacterial disease. With the tremendous improvement in modern means of transportation, travel has increased to such an extent as to become a problem to guardians of the public health. As Stallybrass⁷ has indicated, the principal bodies of migrating persons may be classed as (1) emigrants, (2) pilgrims, (3) transient laborers, (4) seafaring populations, railway and air personnel, (5) commercial travelers, merchants, itinerant traders, (6) tourists, (7) vagrants, (8) persons attending markets, fairs, musical or gymnastic contests, football or baseball matches and bull-fights, and (9) soldiers. The Chicago outbreak of amebic dysentery during the Century of Progress exposition is a comparatively recent example of the epidemic possibilities in travel and large gatherings. Leprosy has been found among Mexican railroad workers in Texas. Chinese workers, particularly those smuggled into the country, may act as a grave source of infection with leprosy, cholera, smallpox and amebic dysentery.

A study of the history of epidemics suggests that failure in prevention and control has been due to ignorance of causes and to lack of cooperation. The first essential in prophylaxis is an accurate knowledge of etiology. Then an adequate power of administration is required for education of the public and for effective control of causative factors. Preventive medicine is influenced at every point by the general social questions of education, economics and social welfare. Given a

proper public health organization, the first necessity in control of an epidemic is early notification of cases as they occur. This implies complete cooperation on the part of all practicing physicians. Then the proper quarantine measures, isolation of contacts and carriers, and destruction or nullification of the reservoir of infection are carried out by the proper authorities. The most serious situations in such work are caused by the congested urban populations, the nodal centers of infection, and the slums, where overcrowding, insanitary conditions and ignorance result in endemicity of the infective disease. The incidence of infectious diseases and mortality from them are considerably greater in urban than in rural populations within the same geographic region. Increasing urban congestion and gregariousness is conducive to the development of epidemics. The best preventive measure is the destruction of slums and encouragement of the movement away from cities. The latter should be used merely for the purposes of commerce, while actual home life should be carried out under suburban and rural conditions.

Modern means of communication enable health authorities to keep informed of serious disease manifestations anywhere on the globe. International organization and cooperation are particularly necessary in this connection. In 1907 the Office international d'hygiène publique was established at Paris. By 1929 forty-nine countries had signed the agreement. The statistical bureau of the League of Nations was established at Geneva in 1919. Its weekly, monthly and annual bulletins contain information as to the incidence of plague, cholera, yellow fever, typhus, smallpox and other epidemic diseases. Because of congestion of population, poverty and climate, the Far East has always been a source of epidemics and pandemics. F. Norman White,⁸ in his report to the Health Committee of the League of Nations on the prevalence of epidemic disease in the Far East, has studied the port procedures of maritime sanitation in various countries and has established a standard for class A ports from the standpoint of hygiene and prevention of epidemic disease. This standard requires that there be a qualified and adequate health staff, apparatus for fumigation of large vessels at anchor, a trained staff and means for the capture and extermination of rats, a quarantine station suitable for detention and observation of deck passengers and disinfection of their effects, an adequately equipped bacteriologic laboratory, an infectious disease hospital, a satisfactory water supply, and the machinery and legislation necessary for dealing with vital statistics, including the registration of cases and deaths from dangerous communicable diseases. White has suggested the creation of a central international epidemiologic intelligence bureau for the Far East to gather, correlate and render available the necessary data concerning contagious diseases and coordinate administrative measures in their

⁷ Stallybrass, C. O. *The Principles of Epidemiology and the Process of Infection*. New York: The Macmillan Company, 1931.

⁸ White, F. N. *The Prevalence of Epidemic Disease and Port Health Organization and Procedure in the Far East*. Geneva, 1923.

control There is no reason why such an organization cannot be truly international in scope and activity

Modern epidemiology is a complex science devoted to a study of herd diseases, the conditions of their origin and the means for their control It utilizes biostatistics and laboratory and field studies as well as administrative and legal powers in its efforts to understand and control epidemics The physician at large may profitably broaden his hygienic vision by becoming epidemic minded Such a physician will gladly report all transmissible diseases, out of duty to the community His interest in the individual patient will be based on a broad understanding and sympathy with the aims of modern preventive medicine

Current Comment

CAN THE LEOPARD CHANGE ITS SPOTS?

The "patent medicine" interests have decided that another housecleaning is called for History repeats itself! Nearly thirty years ago, when the present national Food and Drugs Act was under consideration in Congress, the "patent medicine" people, through their publicity department, let it be known that all members of the "Proprietary Association of America"—as the organized "patent medicine" business was then called—would conform to certain rules of truthfulness and decency in advertising their wares Unfortunately, the list of members of the Proprietary Association of America was never made public! About a year ago—in August 1934—there was published in the *Editor and Publisher* an article entitled "Proprietary Association Begins Clean-Up" In this it was stated that the Proprietary Association—the present name for the organized "patent medicine" interests—had created an Advisory Committee on Advertising, which would draw up an "Outline of Ethical Practices in Proprietary Advertising" In June of this year the *New York Times* reported that the Proprietary Association was about to "launch a comprehensive program of research" The function of this "Research Committee," it appears, is to gather evidence to rebut any damaging attacks on "patent medicines" The same article in the *Times* stated that Dr Frederick J Cullen, general representative of the Proprietary Association, was also serving, ex officio, as secretary Dr Cullen, as the *Times* pointed out, was formerly Chief of Drug Control of the Department of Agriculture There has recently been issued (Aug 28, 1935) what is presumably one of the first pieces of work in this field In April 1933 the Department of Agriculture issued under Dr Cullen's name a bulletin warning the public against the coated laxatives that contain phenolphthalein The bulletin was a straightforward, valuable statement of fact, pointing out the potential dangers of phenolphthalein when used indiscriminately by the public in the form of "patent medicines" put up as "pressed fruits, mints, small cubes or lozenges" and "packaged attractively" Now (Aug 28, 1935) the Proprietary Association, under Dr

Cullen's name, sends Bulletin 6365 to all its members In this bulletin Dr Cullen completely reverses himself on phenolphthalein In it he states that the government bulletin (April 1933) issued by him was based on information gathered from medical textbooks and from a report made by a physician in one of the medical journals (the report of the case of a small child who ate a complete box of the "candy laxative" known as "E-Lax" and promptly died) It appears that Dr Cullen today, in his connection with the "patent medicine" interests, has decided, "a more exhaustive study of the effects of phenolphthalein since the issuance of that article (April 1933) has resulted in a change in my opinion as to its harmful effects" This "exhaustive study" seems to have exhausted the doctor's judgment, one wonders where he found the new evidence on which the reversal of his opinion was based Have new controlled studies been reported to warrant such a remarkable change of front or is there just a new job? Undoubtedly the "patent medicine" interests are on the defensive and presumably will spare no expense to convince a gullible public that its business is a public-spirited activity But those who have followed critically the devious methods of the "patent medicine" business for more than a quarter of a century may be excused for holding to the well established opinion that the leopard does not change its spots

THE PATHOMETRISTS

This month the Universal Society of Pathometrists held their sixth annual session According to the newspapers that reported this notable event, "members are physicians who employ the pathoclast instrument, a vibratory mechanism used in diagnosis and treatment" Anybody who happened to read this item might have been convinced that the pathometrists were a new type of scientist representing a distinct advance over what scientific medicine has been able to accomplish in the diagnosis and treatment of disease Nevertheless the pathometrists are merely a hybrid variety of the genus chiropractor They are the chiropractors who use a device developed by the Pathometric Laboratories The Pathometric Laboratories manufacture the pathoclast and the pathoneurometer It appears that Dr J W Wigelsworth of Los Angeles is the inventor of the pathoclast and also the founder of the Anabolic Food Products Wigelsworth, whose name must have been an inspiration of a higher power, expands that cognomen by the letters "D N," which may mean "Doctor of Naprapathy" or "Doctor of Naturopathy" What a marvelous name for a vibrator promotion Wigelsworth really is! As far back as 1918 Wigelsworth was promoting a system of color and homeopathic diagnosis With the passing of Abrams, the real originator of the "clast" and "meter" apparatus, Wigelsworth changed to his new machinery The pathoclast appears as another of the fifty-seven varieties of imitations of the Abrams apparatus The pathoneurometer was no doubt developed to compete with Chiropractor B J Palmer's neurocalometer Using a phrase popularized by that master of comedy Ben Bernie, the "anabolic foods" are the nuts!

Association News

RADIO BROADCASTS

The American Medical Association will broadcast over the Blue network of the National Broadcasting Company at 5 p. m. eastern standard time (4 o'clock central standard time, 3 o'clock mountain time) October 1 and each Tuesday thereafter, presenting a dramatized program with incidental music under the general theme of "Medical Emergencies and How They Are Met." The title of the program will be "Your Health." The program will be recognizable by a musical salutation through which the voice of the announcer will offer a toast "Ladies and Gentlemen, Your Health!" The theme of the program will be repeated each week in the opening announcement, which informs the listener that the same medical knowledge and the same doctors that are mobilized for the meeting of grave medical emergencies are available in every community, day and night, for the promotion of the health of the people. Each program will include a brief talk dealing with the central theme of the individual broadcast.

The October schedule is as follows:

October 1	Burns	Morris Fishbein	M.D.
October 8	Hazards from Foreign Shores	W. W. Bauer	M.D.
October 15	Unconsciousness	Morris Fishbein	M.D.
October 22	Asphyxiation	W. W. Bauer	M.D.
October 29	Poisonous Plants and Insects	W. W. Bauer	M.D.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

COLORADO

Promotions at Medical School—Dr. James M. Shields, associate professor of ophthalmology, and Dr. Claude E. Cooper, associate professor of otolaryngology, have been appointed heads of their departments at the University of Colorado School of Medicine, Denver.

Memorial for Physician—The Pueblo Clinical and Pathological Society recently presented a check for \$30 to the library of the Medical Society of the City and County of Denver to purchase new medical books in memory of Dr. Seymour D. Van Meter, a past president of the latter society. Each book purchased with this money will be inscribed "This book is presented to the library in memory of S. D. Van Meter, M.D., by the Pueblo Clinical and Pathological Society." Dr. Van Meter died in February 1934. For many years he was secretary of the state board of medical examiners.

State Medical Election—Dr. Walter W. King, Denver, was installed as president of the Colorado State Medical Society at the annual meeting in Estes Park, September 4-7. Dr. Arthur J. Markley, Denver, was chosen president-elect and vice presidents elected are Drs. Leo W. Bortree, Colorado Springs, Herman C. Graves, Grand Junction, Archie C. Sudan, Kremmling, and Clarence W. Bixler, Erie. The next annual session will be held in Glenwood Springs, Sept. 9-12, 1936, with headquarters in the Hotel Colorado. There were 375 members of the society, guests and nonmembers and 176 other persons registered at the meeting.

GEORGIA

Dr. Crile to Give McRae Lecture—Dr. George W. Crile, Cleveland, will present the Floyd Wilcox McRae Memorial Lecture of the Fulton County Medical Society, October 11. His address will be entitled "The Genesis and Practice of Medicine."

Births and Deaths Increase—A total of 65,615 live births were registered in Georgia in 1934, as compared with 60,744 in 1933, according to the state department of health. An increase of 4,406 deaths was recorded for 1934, a total of 35,590 deaths for the year as compared with a total of 31,184 in 1933. The infant mortality rate showed an increase of 17.1 per cent, it was stated, the rate in 1934 was 78.7 per thousand live births, in comparison with 67.2 in 1933.

ILLINOIS

Society News—At a meeting of the Peoria City Medical Society, September 3, speakers included Drs. William A. Malcolm on endometriosis, Hugh E. Cooper, backache, Walter H. Baer, early symptoms and treatment of dementia paralytica, and John M. McCuskey, common skin diseases. Dr. Nelson M. Percy, Chicago, addressed the society, September 17, on "Surgery of the Superior Hypogastric Plexus of the Sympathetic Nervous System."—At a meeting of the Jefferson Hamilton County Medical Society, Mount Vernon, a symposium on obstetrics was presented by Drs. Thomas B. Williamson, Harry G. Thompson, William G. Parker, all of Mount Vernon, Frank B. Hiller, Pinckneyville, and John Beverly Moore, Benton.—Dr. Max S. Wien, Chicago, addressed the Stephenson County Medical Society at Freeport, August 28, on "Relation of Dermatology to General Medicine."

Chicago

Dr. Coutard to Give McArthur Lecture—Dr. Henri Coutard, chief of the department of roentgen therapy of cancer, Curie Institute, University of Paris, will deliver the twelfth Lewis Linn McArthur Lecture of the Frank Billings Foundation of the Institute of Medicine of Chicago, October 1, at the Chicago Woman's Club. The subject of his illustrated lecture will be "The Conception of Periodicity as a Possible Directing Factor in the Roentgen Therapy of Cancer." The meeting will be a joint session with the Chicago Laryngological and Otolological Society.

INDIANA

Physicians in Chamber of Commerce—Members of the Montgomery County Medical Society, at a meeting July 25, voted to form an organized division of the Crawfordsville Chamber of Commerce. According to the *Journal of the Indiana State Medical Association*, this group will serve as a separate organization from the county medical society and its activities will be centered on business problems of the profession.

IOWA

Personal—Dr. Philip I. Crew has been appointed health officer of Marion.—Dr. Willard W. Hayne, Des Moines, has been appointed medical supervisor of athletics at the State University of Iowa, Iowa City, succeeding Dr. Arthur S. Fourn.

Society News—The Louisa County Medical Society held a fish fry at Chautauqua Park, Columbus, August 8.—Dr. Harold B. Cushing, Montreal, Canada, will discuss "Prevention and Treatment of Scarlet Fever" before the Linn County Medical Society, Cedar Rapids, October 16.—Dr. John F. Erdmann, New York, addressed the Des Moines Academy of Medicine and the Polk County Medical Society, September 13, on "Common Duct Injuries and Their Reconstruction."

KANSAS

Advisory Committee for Health Projects—Drs. Barrett A. Nelson, Manhattan, and Forrest L. Loveland, Topeka, have been appointed representatives of the state medical society on an advisory committee to study health projects to be undertaken with funds made available under the Social Security Act. The committee is composed of representatives from the medical, dental, hospital and nursing professions of the state.

Dr. Brown Made Professor of Hygiene—Dr. Earle G. Brown, Topeka, since 1925 secretary of the Kansas State Board of Health, has been appointed professor of hygiene and preventive medicine at the University of Kansas School of Medicine, Kansas City. Dr. Brown graduated from Northwestern University School of Medicine, Chicago, in 1913, and engaged in private practice in Topeka from 1914 to 1917. In 1919 he was appointed health officer of Topeka, serving in this capacity until he was appointed secretary of the state board of health. Dr. Brown will retain his position with the state board.

Deaths of Physicians—In a study of the deaths of 170 Kansas physicians reported in the last four years, chronic myocarditis was found to be the leading cause of death, being responsible for twenty-seven deaths, according to the state medical journal. Cancer and chronic nephritis were second, diabetes and coronary thrombosis were fourth, cerebral hemorrhage was sixth. Motor vehicles caused five of the seven accidental deaths. Excluding deaths from violence, the average age at death was 67.3 years. The oldest was 96. Excluding deaths from external violence, sixty-one deaths, or 41 per cent, were attributed to diseases of the cardiovascular system. Of the 20,011 deaths of all persons reported in the state in 1934, only 25 per cent were due to cardiovascular disease.

KENTUCKY

State Medical Meeting at Louisville—The eightieth annual session of the Kentucky State Medical Association will be held in Louisville at the Brown Hotel, September 30 to October 3. The annual oration will be delivered by Dr. Sumner L. S. Koch, Chicago, at the banquet Wednesday evening, October 2, on "Injuries to the Hand." The oration in surgery will be given by Dr. Samuel C. Smith, Ashtland, and the oration in medicine by Dr. James H. Pritchett, Louisville. Among papers to be presented are the following:

Dr. Ernest B. Bradley, Lexington: Evaluation of the Newer Methods of Handling Pulmonary Tuberculosis.
Dr. Rockwell Emerson Smith, Henderson: Contract Practice.
Dr. Joseph D. Northcutt, Covington: Social Trends in Medicine.
Dr. James Duffy Hancock, Louisville: Modern Management of Tumors of the Breast.
E. D. Rose, D.D.S., University of Tennessee College of Dentistry, Memphis: What the Physician Should Know About Periodontal Lesions.
Dr. Wilford A. Risteen, Lebanon: Diet in Relation to Abdominal Infections.
Dr. Harry D. Abell, Paducah: Ocular Manifestations of Systemic Disease.
Dr. Benjamin F. Wright, Seco: Emergency Management of Fractures.

There will also be a symposium on obstetrics presented by Drs. Scott D. Breckenridge, Lexington, Charles L. Sherman, Millwood, and Amphas W. Davis, Madisonville. Dr. Joshua B. Lukins, Louisville, will deliver his presidential address at a public meeting Tuesday evening, October 1, at which also Judge Elwood Hamilton, Louisville, will speak.

MICHIGAN

Graduate Courses—The University of Michigan Medical School, Ann Arbor, and the Michigan State Medical Society will open a series of short graduate courses, September 30 in Grand Rapids, Flint, Bay City, one jointly for Battle Creek and Kalamazoo, and one for Manistee, Traverse City and Cadillac. By request of Upper Peninsula physicians the program for that section will be deferred until May 1936. The courses will be held one day a week for eight weeks, the week of October 14 to be omitted to permit attendance at the Interstate Postgraduate Medical Assembly in Detroit. Subjects will include maternal welfare, gynecology, pulmonary disease, diseases of joints, neuropathology, metabolic diseases, diseases of the blood and blood-forming organs, child welfare, skin diseases, cancer, genito-urinary diseases, anorectal diseases, fractures and biliary tract disease. One week courses will be conducted at Detroit and Ann Arbor. Information may be obtained from the department of graduate medicine, University Hospital, Ann Arbor.

MINNESOTA

Society News—Dr. Arthur N. Collins, Duluth, was elected president of the Northern Minnesota Medical Association at its annual meeting, August 12, succeeding Dr. George I. Badeaux, Brainerd. The next annual meeting will be held in Fergus Falls.

Health Survey—Of the \$3,450,000 federal allocation for a national public health survey, Minnesota will receive \$108,500 to carry out its studies, newspapers report. A house to house canvass will be made to determine the prevalence of chronic diseases, physical examinations will be given and studies of medical facilities will be carried out.

Dr. Wangenstein Awarded Philadelphia Prize—The Samuel D. Gross Prize for 1935 has been awarded to Dr. Owen H. Wangenstein, professor of surgery, University of Minnesota School of Medicine, Minneapolis, for an essay entitled "The Therapeutic Problem in Bowel Obstruction." The prize is awarded every five years by the Philadelphia Academy of Surgery to the writer of the best original essay on surgical pathology or surgical practice founded on original investigations.

NEW JERSEY

Hospital News—The new Zurbrugg Hospital, Riverside, with a capacity of forty beds, was opened recently after a delay of three years. The hospital was built with funds left by Theophilus J. Zurbrugg, but no money was available for operating expenses until the Burlington County Board of freeholders agreed to aid in its maintenance. The institution has been in operation since 1915 with a capacity of twelve beds.

Society News—Dr. Arthur C. Christie and Ross Garrett, Washington D. C., addressed the Essex County Medical Society, Newark, September 12, on "Coordination of Resources for Medical Care."—Dr. Albert F. R. Andresen, Brooklyn, and Lloyd K. Riggs, Ph.D., Rutgers University, New Brunswick, addressed the Bergen County Medical Society, Hackensack, September 10, on "Focal Infection" and "Evaluation of Antiseptics in Modern Practice," respectively.

NEW MEXICO

District Health Organization—Health work in New Mexico has been organized into ten districts, each under the supervision of a full time health officer. Nine officers have already been appointed, with headquarters as follows: Drs. Elroy F. McIntyre, Santa Fe, Edgar B. Beaver, Gallup, James R. Scott, Albuquerque, Charles W. Gerber, Las Cruces, William W. Johnston, Las Vegas, Owen E. Puckett, Carlsbad, Frank W. Parker Jr., Silver City, Julian O. Long, Los Lunas, and Leonard A. Dewey, Clovis (temporary).

NEW YORK

Society News—Dr. Spencer T. Snedecor, Hackensack, N. J., addressed the Suffolk County Medical Society, Sayville, July 31, on treatment of burns.—The program of the Westchester County Medical Society, September 17, was presented by members of the staff of Grasslands Hospital, Valhalla, Drs. William G. Childress, White Plains, Morley T. Smith and George C. Adie, New Rochelle, who gave a symposium on bronchiectasis.

New York City

Hospital News—Dr. Bela Halpert, assistant professor of pathology and surgery, Yale University School of Medicine, New Haven Conn., has been appointed head of the division of pathology and associate director of laboratories at the Jewish Hospital of Brooklyn.—Misericordia Hospital opened a new radiology department July 24. It has units for high voltage therapy, diagnostic radiography, fluoroscopy, urology and fracture work.

Personal—Dr. Alva Churchill, associate secretary-general of the International Association for Prevention of Blindness and executive secretary of the International Union Against Tuberculosis, recently arrived in the United States for a series of conferences in various cities on policies and procedures in the world-wide fight against blindness and tuberculosis. Dr. Churchill is the guest of the National Society for the Prevention of Blindness and the National Tuberculosis Association.

City Collects for Accident Cases—Special efforts by the department of hospitals to obtain reimbursement for the city in accident cases in which victims have been cared for in municipal hospitals have resulted in steadily increased collections during the current year, the department reports. In December 1934 the collections amounted to \$930 and by June they had increased to \$5,688. A total of 4,500 potential liability cases have been referred to the department since October 1934. Of this number 650 were closed after investigation because of nonliability or an insolvent defendant, about 1,500 cases in which the department has an interest are now pending. The department also reported that collections had been made in 179 cases not in court.

Positions Open in Health Department—Open competitive examinations for two positions in the New York City Department of Health, research pediatrician (tuberculosis immunization) and epidemiologist, are announced by the Municipal Civil Service Commission. The pediatrician is expected to continue investigations already under way on the use of the Calmette or BCG vaccine, conduct research on pneumonia serums and similar problems. Requirements include graduation from a recognized medical school, experience in the use of vaccines and serums, including specialized experience with BCG vaccine. The salary is \$3,000 a year. Duties of the epidemiologist will be to investigate incipient outbreaks of communicable illness and terminate the transmission of infection at the earliest possible moment. Requirements include graduation from a recognized medical school and two years of special training or experience in epidemiologic work in a state or city health department or the equivalent. The salary is \$5,500 a year. For both positions candidates must have licenses to practice medicine in New York before they can be certified. Candidates must be between 25 and 50 years old. Applications will be received until October 2. Further information may be obtained from William H. Allen, secretary of the civil service commission, Room 1400, Municipal Building, Manhattan.

NORTH CAROLINA

Society News—Dr. Verling K. Hart, Charlotte, addressed the Guilford County Medical Society, Greensboro, August 1, on "Bronchoscopic Observations on Bronchial Obstruction and Bronchiectasis."—Speakers at the regular meeting of the Catawba Valley Medical Society, Morganton, September 10, were Drs. Lester A. Crowell Jr., Lincolnton, on "Vaccination for Poliomyelitis," Samuel F. Ravenel, Greensboro, "Nervous Children," and D. Lesesne Smith, Spartanburg, S. C., "Acute Infectious Diseases and Diarrhea in Children."

Report of Duke Hospital—The annual report of Duke Hospital, Durham, states that 80 per cent of its patients in 1934 came from counties outside of Durham, ninety-three of the 100 counties in the state were represented. During 1934 the hospital cared for 236 patients a day at a cost of \$385,782. The patients paid 43.5 per cent of the cost, counties and cities contributed 34 per cent, other contributions amounted to 31 per cent, and the hospital made up the remainder from its endowment. The outpatient department reported 40,949 visits.

OHIO

Personal—Dr Joyce I. Hartman has been appointed supervisor of health education in the Cleveland public schools, succeeding Dr Lyman W. Childs, who had held the position since 1910.

Hospital News—Babies' and Children's Hospital, Cleveland, one of the University Hospitals group, was to be reopened August 5, after having been closed for two years as an economy measure. Dr Henry J. Gerstenberger will head the department of pediatrics and Dr Carl H. Lenhart, the department of surgery.

Society News—Drs Ralph H. Major, Kansas City, Mo., and Max M. Peet, Ann Arbor, Mich., addressed the Cleveland Academy of Medicine, September 20, on medical and surgical aspects, respectively, of arterial hypertension. Dr Philip H. Kreuscher, Chicago, addressed the Summit County Medical Society, Akron, September 3 on "Back Injuries and Inflammations." Dr Walter M. Simpson, Dayton, discussed fever therapy before the Greene County Medical Society, Xenia, August 1.

Rock Gardens and the Malaria Increase—Eighty-five cases of malaria have been reported to the state health department in the first eight months of the year, thirty-four of them in July and thirty-eight in the first twenty-three days of August. In 1934 there were 104 cases. *Ohio Health News* points to the current fad for rock gardens as one of the causes for an increase of the anopheles mosquito, the hollows and crevices in the rocks provide facilities for development. Other causes are a similar fad for small pools as water gardens and fish ponds, carelessness in leaving empty cans, bottles and discarded automobile tires about houses and, in the country and small villages, continued use of the old fashioned rain barrel.

OREGON

Society News—Dr James Tate Mason, Seattle, President-elect, American Medical Association, addressed the Eastern Oregon Medical Society at a meeting in Ontario, July 27.

Personal—Drs F. Floyd South and Archie C. Van Cleave, Portland, have been appointed to the state board of health to succeed Drs Albert Mount, Oregon City, and Joseph P. Brennan, Pendleton, respectively.

Health Officers' Conference—A conference of city and county health officers was held in Portland, September 16-18. Mornings were given over to clinics at the University of Oregon Medical School, covering antepartum and postpartum conditions and venereal disease. The first afternoon program included discussions of blindness, heart disease, cancer and medical dentistry, the second, venereal disease, and the third, maternal and child health. Among speakers were Drs Frederick A. Kiehle, Homer P. Rush, Thomas A. Davis, Morris L. Bridgeman, Lendon Howard Smith, all of Portland, and Edith P. Sappington of the U. S. Children's Bureau.

PENNSYLVANIA

District Meeting at Reading—The second councilor district of the Medical Society of the State of Pennsylvania held its annual meeting at the Reading Country Club, September 19. The scientific program included papers by Drs Philip F. Williams, Philadelphia, on Intrapartum Care in Relation to Maternal Mortality, Clarence A. Patten, Philadelphia, "Mental Hygiene Viewpoints on Sterilization of the Unfit," Moses Behrend, Philadelphia, "Collapse Therapy in Pulmonary Tuberculosis," and Brig. Gen. Matthew A. DeLaney, commandant of Carlisle Barracks, "What the Medical Department of the U. S. Army Has Contributed to Human Progress." Speakers on organization problems were Drs William H. Mayer, Pittsburgh, on public relations, Francis F. Borzell, Philadelphia, medical service plans, George L. Laverty, Harrisburg, emergency medical relief, and Chauncey L. Palmer, Pittsburgh, legislative problems concerning public health. Testimonials were presented to three members who have practiced medicine fifty years: Drs Anthony F. Myers, Blooming Glen, Josiah B. Keylor, Cochranville, and Levi S. Walton, Jenkintown.

Philadelphia

Hospital News—Dr Frank E. Leivy delivered the first of a series of public health lectures at Mount Sinai Hospital, September 18, on "What You Should Eat and Why." Dr Joseph Edeiken will give the second lecture, October 16, on "Heart Disease: Its Prevention and Care."

SOUTH CAROLINA

Graduate Assembly in Anderson—The first Piedmont Post Graduate Clinical Assembly was held at the Anderson County Hospital, Anderson, September 3-5, with the following program:

Dr William A. Mulherin, Augusta, Ga., Preventive Pediatrics.
Dr Richard M. Pollitzer, Greenville, Infantile Paralysis.
Dr D. Lesesne Smith, Spartanburg, and Saluda, N. C., Everyday Pediatrics.
Dr Joseph Warren White, Greenville, Recent Progress in the Care of Hip Fractures.
Dr George H. Bunch, Columbia, Suppurative Pericarditis.
Dr A. Johnson Bulst, Charleston, Cancer of the Colon.
Dr Joseph H. Cannon, Charleston, Practical Points in Diagnosis and Treatment of Heart Disease.
Dr Kenneth M. Lynch, Charleston, Pathology of Common Cardiac Lesions.
Dr Allen I. Josey, Columbia, Differential Diagnosis of Chronic Digestive Disorders.

One session was held jointly with the South Carolina division of the Southeastern Surgical Congress. At a banquet meeting with the Anderson County Medical Society, speakers were Drs Samuel E. Harmon, Columbia, president of the South Carolina Medical Association, on "Relationship Between Public Health and Government Activities and the Practice of Medicine," Kenneth M. Lynch, Charleston, "Doctors for South Carolina," and Foster M. Routh, Columbia, "The County Health Unit." The assembly was organized last April for graduate instruction of physicians with Dr Edgar A. Hines, Seneca, president, Dr Jack D. Parker, Greenville, vice president, and Dr Archer L. Smethers, Anderson, secretary.

WASHINGTON

State Medical Election—Dr Delmar F. Bice, Yakima, was elected president of the Washington State Medical Association at the annual session at Everett in August. Dr Curtis H. Thomson, Seattle, was reelected secretary. Next year's meeting will be held in Yakima.

WISCONSIN

Personal—Citizens of Mauston held a public reception July 21 in honor of Dr James S. Hess Sr., who has retired after forty-two years of medical practice. A silver plaque was presented to Dr Hess, who is 70 years old. Dr Harry P. Bowen has been appointed postmaster of Watertown for a four year term.

Position Open for Health Officer—The state bureau of personnel, Madison, announces an open competitive examination for the position of assistant state health officer, open to candidates who are citizens of the United States and who have been residents of Wisconsin for one year. Minimum qualifications are as follows: training equivalent to that represented by graduation from a medical school of recognized standing with special training in the field of tuberculosis prevention and other public health work, possession of, or eligibility for, a valid license to practice medicine in Wisconsin, extended professional experience, five years of which shall have been in responsible public health and related work, familiarity with accepted methods and practices in preventive medicine, ability as a public speaker, administrative ability, tact, judgment and good physical condition. Applications will be received until September 28.

Community Honors Dr Nuzum—The Rock County Medical Society, the Janesville Civic and Industrial Council and the staff of Mercy Hospital sponsored a "Golden Medical Holiday," September 17, in honor of Dr Thomas W. Nuzum, who has completed fifty years in the practice of medicine. At a public testimonial dinner in the evening at the Janesville High School, Dr Morris Fishbein, Chicago, Editor of *THE JOURNAL*, made an address on "Medical Progress in the Last Fifty Years." In the morning there were surgical clinics, including an operation performed by Dr Nuzum and clinical conferences in the various departments of Mercy Hospital. After a luncheon at the Janesville Country Club, a scientific program was presented which included papers by Dr Franklin R. Nuzum, Santa Barbara, Calif., read by Dr Thomas Ochsner, Nuzum, Janesville, and Dr John W. Nuzum, Chicago, all sons of the guest of honor. Other papers were read by Drs Nelson M. Percy and Harry Culver, Chicago, and Dr Joseph S. Evans, Madison.

Dr Nuzum was born in Viroqua, Aug 27, 1860, was graduated from Rush Medical College, Chicago, in 1885, and practiced in Albany and Brodhead before going to Janesville in 1906. During the World War he served as a first lieutenant at Fort Sheridan, Ill., and later at Camp Custer, Mich. Dr Nuzum's three sons are all graduates of their father's alma mater.

ALASKA

Dr DeVighe Leaves Alaska—After more than thirty years practice in Alaska, Dr Harry C DeVighe is moving to Santa Barbara, Calif. Dr DeVighe was secretary of the Alaska Board of Medical Examiners for twenty years, twelve years commissioner of health, which position he resigned in 1934, fifteen years secretary of the Territorial Medical Association, and seven years chief surgeon of the Alaska Juneau Gold Mining Company. Dr William P Blanton, Juneau will succeed Dr DeVighe as secretary of the association and in the mine medical work.

PUERTO RICO

Fellowships to Puerto Ricans—Eight Puerto Ricans were recently designated by Dr Eduardo Garrido Morales, commissioner of health, to receive fellowships granted by the Rockefeller Foundation's International Health Division for study in the United States. Those chosen are Drs Norberto A. Quinones, who will study bacteriology, Juan Basora and Victor J. Montilla, public health, Abel de Juan, vital statistics and epidemiology, Jose R. Vivas and Libertad R. Gaetan, tuberculosis, and Misses Winifred M. Mendez and Carmen L. Riera, public health nursing.

GENERAL

Grants Available for Research—The division of medical sciences of the National Research Council will hold a special meeting in November for the consideration of applications for grants in the field of medicine. Applications must be on file with the secretary of the Committee on Grants-in-Aid, Clarence J. West, Ph.D., 2101 Constitution Avenue, Washington, D.C., not later than October 1. Applications received after October 1 and before Feb 1 1936, will be acted on at the next regular meeting in March 1936.

Poliomyelitis Declines—The New York City Department of Health reported September 15 that 238 cases of poliomyelitis had been reported during the week ended September 13, compared with 289 for the preceding week. The high point of the outbreak was reached during the week ended August 30, when 359 cases were reported. The total for the year was 1,552, with fifty-nine deaths. It was reported September 11—Fifty five active cases were reported from Louisville, Ky., September 2, the total since June 15 is seventy-four. Two deaths have occurred.

Health Education Institute—The American Public Health Association's fourth health education institute will be held in Milwaukee, October 4-6, preceding the annual session of the association. The subject of this year's institute will be "Health Education, with Special Reference to Smaller Cities and Rural Communities." Leaders of the discussions will be W. Frank Walker, Dr.P.H., director of the division of health studies, Commonwealth Fund, New York, Wesley Maurer of the school of journalism, University of Michigan, Ann Arbor, Evert G. Routzahn, editor of the public health education section of the *American Journal of Public Health* and Ruth E. Grout, Cataugaus County School Health Service, Olean, N.Y.

Resolution on Professional Relationships—At its recent annual meeting in Portland, Ore., the American Pharmaceutical Association adopted a resolution expressing "the belief that it is essential to good medical care and to the welfare of the public that the personal relation between those engaged in the practice of medicine, dentistry, pharmacy and allied professions and their clientele be preserved." The action was taken, the resolution said in view of the fact that certain proposed methods of providing medical care to the public through federal, state and private agencies contemplate corporate practice involving elimination or serious interference with the personal and private relations between members of the medical, dental, pharmaceutical and nursing professions and their clientele.

Society News—Dr Roscoe C. Giles, Chicago, was elected president of the National Medical Association at its annual session in New Orleans in August. Dr John T. Givens, Norfolk, Va., William D. Giles, DDS, Chicago and Emile J. La Branche, New Orleans were elected vice presidents and Dr Charles A. Lanon, South Brownsville Pa., secretary. Next year's meeting will be held in Philadelphia. The Western Orthopedic Association will hold its annual session at San Francisco October 25-26, with a program of addresses and

clinical meetings at San Francisco, Stanford and Mount Zion hospitals. Dr Merrill C. Mensor, 490 Post Street San Francisco, is secretary.—Dr Henry E. Young, Victoria, B.C., was elected president of the Western Branch of the American Public Health Association at its recent annual meeting at Helena, Mont., and Dr William P. Shepard, San Francisco, secretary. Next year's meeting will be held in Vancouver, B.C.—The Central Association of Obstetricians and Gynecologists will hold its seventh annual meeting in Omaha, October 10-12, at the Hotel Fontenelle.—The American Dermatological Association will hold its next annual meeting at the New Ocean House in Swampscott, Mass., June 4-6, 1936.—The twenty-fourth annual Safety Congress and Exposition will be held in Louisville, Ky., October 14-18.—The International Medical Assembly of the Interstate Postgraduate Medical Association of North America will be held in Detroit, October 14-18 with headquarters at the Masonic Temple.—The Society for Plastic and Reconstructive Surgery will hold its annual meeting at the Hotel Statler, Detroit, October 18-19.

American Hospital Association—The annual session of the American Hospital Association will be held in St. Louis, September 30 to October 4 under the presidency of Robert Jolly Houston, Texas. Among physicians listed on the program for addresses are:

- Dr H. Kennon Dunham, Cincinnati: Interpretation of Chest Films with Special Reference to Tuberculosis
- Dr Everts A. Graham, St. Louis: Differential Diagnosis of Chest Films
- Dr Williams McKim Marriott, St. Louis: Conduct of a Convalescent Department of a Children's Hospital
- Dr Robinson Bosworth, Rockford, Ill.: Rehabilitation of Patients in the Sanatorium
- Dr Magnus C. Petersen, St. Peter, Minn.: The Hospital Library in Relation to Psychiatric Research
- Dr George Harvey Agnew, Toronto: Governmental Methods of Providing Care for the Indigent Sick in Canada Compared with the United States
- Dr Nathaniel W. Faxon, Boston: Past, Present and Future Status of Governmental Hospitals in the Care of the Indigent Sick and Their Relation and Effect on Nongovernmental Public Hospitals

The American Protestant Hospital Association will hold its meeting in St. Louis September 28-30, and the American Occupational Therapy Association will meet simultaneously with the American Hospital Association.

Death Rates in 1934—The U.S. Bureau of the Census announces that there were 1,396,903 deaths in the United States in 1934, a mortality rate of 11 per thousand estimated population, an increase over the rate for 1933, which was 10.7. The bureau has issued a comparative summary of mortality statistics for the last three years, giving mortality rates for all causes of death. The tuberculosis death rate fell from 62.9 per hundred thousand of population in 1932 to 56.6 in 1934, while the rate for cancer and other malignant tumors rose from 102.2 to 106.3 in the two years. The type of cancer most frequently found was that of the digestive tract and peritoneum. Deaths from diabetes increased from 26,368 to 28,000, the rate from 22 to 22.1. The number of deaths from cerebral hemorrhage increased from 94,694 to 97,148. Diseases of the circulatory system caused 333,296 deaths in 1934 compared with 295,509, an increase in rate from 246 to 263.6 per hundred thousand, most numerous were diseases of the myocardium, which caused 136,726 deaths in 1934. The pneumonia death rate was 41.2 in 1932 and 43.3 in 1934 but was 36.4 in 1933. Appendicitis deaths rose slightly, 18,129 in 1934 as compared with 17,111 in 1932. A decrease was shown in deaths from pregnancy, childbirth and the puerperal state, the rates for the three years being 11.1 for 1932, 10.3 for 1933, and 10.2 for 1934. Suicides also showed a downward trend, the rates being 17.4, or 20,927 deaths, in 1932, 15.9, or 19,993 deaths, in 1933, and 14.9, or 18,828 deaths, in 1934. On the other hand, homicides rose from 11,035, or a rate of 9.2, in 1932 to 12,055, or 9.5, in 1934. Primary automobile accidents caused 33,980 deaths in 1934, compared with 29,323 in 1933 and 26,350 in 1932. Air transportation accidents caused 428 deaths in 1934, compared with 434 in 1933 and 386 in 1932. All violent and accidental deaths increased from 117,830 in 1932 and 123,204 in 1933 to 132,022 in 1934.

CORRECTION

Antimeningococcic Antitoxin—In a news item concerning the recent retirement of Dr. Simon Flexner, published in THE JOURNAL, June 22, page 2274, the statement was made that Dr. Flexner "was the first to use the meningococcus antitoxin." The term "antimeningitis serum" should have been used as the statement referred to Dr. Flexner's early work on that serum and not to the recent antitoxin developed by Ferry and used by Hoyne (THE JOURNAL, March 23, p. 980).

Defense of the Civil Population Against Gas Attacks

Further information is now available concerning precautions against gas attacks on the civilian population. The St. John Ambulance Brigade is making comprehensive provision. A scheme of education and training will be in full operation by the autumn. It will include instruction of householders in precautionary measures and the formation of an air raids precautions reserve. Selected officers of the brigade from every county have already been given an intensive course of training, and virtually all the personnel of the London district—some 7,000 men and women—are now instructed in anti-gas precautions and first aid in cases of gas poisoning. The brigade is appointing an officer for every county throughout the country and also for every municipal borough. The duties of these anti-gas precautions officers, as they are called, will be important. After thorough training they will be available in their own areas to advise local authorities as to the safeguarding of the civil population. They will supervise the dissemination of knowledge among householders, who will then be in a position to afford their families all the protection possible against poison gas. They will also organize the air raids precautions reserve. It is believed that many citizens who have not time or inclination to join the brigade as members would be prepared in times of emergency to lend a hand in combating the effects of gas. They will be invited to enroll. Their training will be based on the instruction in the official handbook.

The further task of educating the civil population in anti-gas precautions has been begun by a demonstration showing how a householder can make one of his rooms secure against explosive blasts, metal splinters and poison gas for an expenditure not exceeding \$5. Boarded windows and protective curtains over the doors are the only external evidence that the house is equipped to stand a gas attack. Inside, a back bedroom has been completely fitted as a shelter and contains everything needed for a prolonged occupation—canned foods, drinking water, beds, furniture, a wireless set for receiving news, books and games to pass the time, utensils containing the liquid with which the protective curtains over the door and windows must be kept damp, a garden syringe for spraying the curtains, and gas masks for use if the occupants go out of the room or for emergencies. The masks, of a type approved by the government, are said to remain gas tight for sixty hours. It is asserted that a room so protected and furnished may be occupied for several days.

Investigation of Industrial Dust Diseases

An important advance in the investigation of industrial dust diseases such as silicosis has been made by the invention of a thermal precipitator by Prof. R. W. Whytlaw-Gray and Dr. R. F. Lomax. During investigations of exposure of stone masons to dust, carried out by Mr. H. L. Green and Mr. H. H. Watson of the chemical defense experimental station, who were lent by the war office for the purpose, the instrument was developed and perfected until it reached such efficiency that all particles likely to be of pathogenic importance could be collected. The investigations are part of the program of the committee on industrial pulmonary disease, which was set up by the Medical Research Council in 1930. In the report it is stated that definite conclusions have been reached that it is undesirable for stone masons to work in closed yards, that on calm days the exposure to dust may be three or more times greater than on a windy day, and that punching (shearing off large quantities of stone by heavy blows on a pointed tool)

may account for about half the dust that the mason may inhale. The best preventive measures are the wearing of respirators and brushing the stone free from accumulated dust.

Road Accidents

A table just issued by the minister of transport shows that, in the seven years 1928-1934, 24,385 pedestrians were killed and 533,489 injured, 7,235 bicyclists were killed and 292,098 injured, 16,422 motorists were killed and 545,463 injured. The complete total for the seven years is 48,042 killed and 1,371,050 injured, giving an average of 555 killed and injured every twenty-four hours. For the present year the average so far is 116 killed and 4,016 injured per week. During the seven years the number of killed and injured has been constantly rising—from 170,976 in 1928 to 238,946 in 1934. If the figure is taken as 100 for 1928, the figures for the following years are 103.9, 108.3, 122.1, 124.6, 130.7 and 139.8. The increase for bicyclists is particularly high, taking 1928 as 100, the figure in 1934 was 244.1. The increase of accidents cannot be attributed entirely to increase of automobile traffic, which rose from 2,052,539 vehicles in 1928 to 2,416,908 in 1934. This gives a percentage increase only about half of that for the accidents. The road figures contrast unfavorably with those of train accidents. The number of passengers killed while traveling on railways in 1934 was 17, being one in 96 million.

ACCIDENTS TO CHILDREN

During the present year 500 children have already been killed in road accidents, 103 were cycling. Of 386 killed while on foot, 293 were between the ages of 2 and 9 years. In thirty-two cases children were killed when they escaped from their elders, who were supposed to be in charge of them. There were twenty-two cases of stealing rides and fourteen of chasing a ball into the roadway. Most of the children had been repeatedly warned of the dangers of the roads. The report to the National Safety First Association on the subject states that greater foresight on the part of drivers and closer supervision on the part of parents and others are essential if there is to be any improvement. There were twenty-seven cases in which children were run over when a vehicle restarted or reversed after a stop and the driver failed to notice the child. Older children should be given more "safe-cycling instruction", also it is not wise to teach children to "cross quickly," as it tends to make them run across the road—a dominant factor in their accidents. The report also suggests that fatal road accidents to children might be specially investigated by experts with the same thoroughness as accidents on railways.

A School Sanatorium for Tuberculous Boys

At Frimley, Surrey, a new experiment in the treatment of tuberculosis is being carried out at what is known as the Borough Hill Sanatorium Colony, which is a school for tuberculous boys between the ages of 13 and 19. The Borough Hill Colony, founded in 1929, has already proved so successful as to warrant imitation. Seventy per cent of the boys admitted have found employment and some have gained successes at examinations that would be a credit to a normal school. During the last four years 100 per cent passes have been obtained. The boys live under strict discipline and the control of two physicians. They rise at 7 and have their temperatures taken, breakfast at 8 and at 9 go to the classroom or garden. At 12 they rest. At 1.15 they rest again in their cubicles. At 2 they return to the classroom or garden and at 4 knock off for the day and have their temperatures taken again. At 5 there is another period of rest before tea at 5.30. At 6 there is recreation of a kind graded to their state of convalescence and at 8.45 they go to bed. The school has a model office equipped with typewriters and filing cabinets for training for clerkships. Many acres of the grounds are devoted to gardening, for which occupation many of the boys train. The average time taken

to effect a cure is two and one fourth years. Of 130 patients discharged, thirty-seven obtained posts as clerks and twenty-six as gardeners, thirty-eight obtained other employment, and only fourteen were unable to obtain employment. Eleven were discharged unfit for work. Boys who would have died or who after cure would have been thrown helplessly on the world are returned to society after a few years to lead healthy, useful lives.

Paying Patients in Voluntary Hospitals

The voluntary hospitals (hospitals supported by the voluntary subscriptions of the charitable) were established for the gratuitous treatment of the poor, many patients, however, who do not come under the designation of "poor" cannot afford the cost of private treatment but can pay for treatment in hospitals at charges proportionate to their means. Also there are now numerous methods of diagnosis and treatment that cannot be provided without the aid of the specialized equipment and staff of a hospital except at great expense, if at all. Hospitals that might wish to provide for such persons are prevented by legal obstacles arising from the fact that the need was not foreseen when the legal definition of the hospital was settled. A bill to enable them to do so has been introduced into the house of lords. It provides a uniform method of removing these legal obstacles and at the same time safeguards the interests of the sick poor.

The Falling Birth Rate

In the *Times* Mr. Robert Rankin, M.P., deplores the falling birth rate and says that there is not enough of British stock to quarter fill the empty spaces of the empire. Australia, for example, has a habitable rainfall area of 1,725,000 square miles, which should hold at the present density of the United States 46,000,000 persons, whereas it has only 6,700,000. Up to 1930 the British dominions had a rate of expansion that would double their population every thirty-five years. Now immigration is at a standstill and the birth rate is declining. In Australia the fall has been precipitate, the annual rate of natural increase having sunk from 17.4 per thousand in 1914 to 14.34 in 1921, 1925 and 7.1 in 1934, and it cannot be assumed that it has yet touched bottom.

Mr. Rankin thinks that something should be done to stimulate the growth of population, as has been done in Germany, and, he might have added, Italy. But, like most politicians, he does not fully face either causes or consequences. One of the causes of the decline of the birth rate is industrial depression and unemployment. This in its turn is due largely to political interference in industry and in commerce. The interference of trade unions and, to a less extent, of tariffs has arrested the commercial development of Australia, and its "empty spaces," so deplored by politicians, remain. Mr. Rankin does not tell how to remedy this.

A New Campaign for Road Safety

A new edition of the highway code which takes the place of the pamphlet formerly circulated only to motorists, has been distributed by the government to every house in Great Britain. In a foreword the minister of transport says: "This code is put in your hands in the sincere hope that the observance of its provisions will make the roads safer. Its provisions are a simple summary of the best and widest experience each one written in the resolute desire to prevent that kind of mistake or thoughtless action which may result in bereavement or suffering." All together, 15 million copies are to be distributed of which 80,000 will be in Welsh. The new campaign for road safety is to include a film for motion picture theaters, and a van will visit the seaside resorts and relay the provisions of the code and phonograph talks by the minister and others. Posters in underground stations and in omnibuses in London and in public service vehicles throughout the country will also be used. Large stores, catering firms and others are cooperating in the campaign.

PARIS

Suppression of Street and Radio Noise in Paris

The prefect of police of the department of the Seine, in which Paris is situated, some time ago ordered all honking of automobile horns to cease between 11 p.m. and 7 a.m. Recently, these hours have been changed to 9 p.m. and 8 a.m. Perhaps in the near future an effort will be made to imitate the example of Rome where no honking is permitted at any hour of the day or night. The chief sources of street noise in Paris have been the automobiles, motorcycles, street singers, garbage collectors and pedlers. To these now one can add the radio fans who insist on leaving windows open so that their sound amplifying devices will give the neighbors the benefit of the various broadcasts or records. The Paris police are planning to organize a special antinnoise squad, which is to make the rounds of the city so that on receipt of a single complaint the offenders will be warned. If they continue to offend, a police court summons will follow. French radio stations will be asked to participate in the campaign with broadcasts calculated to convince radio fans that they can obtain better results, without disturbing their neighbors by moderating the power of their sets. As soon as an effective silencer for motorcycles can be found, it will be made obligatory. Any one who has been awakened at 6.30 by the slinging of garbage cans on cement sidewalks will appreciate the order to garbage collectors to perform their task as quietly as possible. Street singing will be limited to those whose cases prove to be worthy and not allowed at an hour when sleep should replace the effort to drown out "harmony murder."

Results of Artificial Pneumothorax for Tuberculosis During Pregnancy

At the May 14 meeting of the Académie de médecine, Rist and Jottras reported their results in the treatment of tuberculous pregnant patients at the Baudelocque Maternity (Professor Couvelaire). The 138 cases included in the report were divided into two groups. In the first there were fifty-eight women in whom the pneumothorax preceded the pregnancy. In the second group were seventy-four in whom this method of treatment was employed during the pregnancy. In the first group, pregnancy occurred while under treatment five years before the report was made, so that one could better judge the end results. Thirty-nine of the fifty-eight in this first group had begun the treatment. Twenty-six, or 67 per cent, of the thirty-nine can be considered cured after five years of observation. Of nineteen women whose pregnancy began less than a year after the pneumothorax treatment twelve (53 per cent) are cured, three years or more after parturition in the case of nine of the twelve, and two years for the other three. In fifteen women in whom pregnancy occurred at a period when the pulmonary lesions were latent, there were thirteen (87 per cent) cures.

In the second group, of seventy-four cases, in which the pneumothorax treatment was begun during the pregnancy, there were thirty-three (45 per cent) favorable results. The earlier in the pregnancy the treatment was employed the better was the prognosis, as shown by comparing the 67 per cent of cures in the first with the 45 per cent of cures in the second group.

If one groups the cases according to whether they showed clinical evidence of pulmonary tuberculosis before or during pregnancy it is to be seen that, of thirty-eight who became pregnant while under treatment, nineteen, or 50 per cent, are cured. On the other hand in thirty-six women in whom the disease appeared during pregnancy, the pneumothorax has cured only fourteen, or 39 per cent. The latter figure emphasizes

the gravity of tuberculosis occurring during pregnancy. Pneumothorax treatment enables one to save the life of both the mother and the child. Its efficacy will more and more limit the indications for therapeutic abortion in the future.

Popularization of Medicine

A plea to the medical profession to enlighten the public as to recent advances is made by R. Massart in the July 14 *Congress Medical*. The article is in line with the publication by the American Medical Association of such a journal as *Hygeia* and the broadcasting program undertaken by the Association. Massart states that the public is often surprised that greater efforts are not being made to keep it informed concerning newer methods of treatment in such a manner that one may keep abreast of medical progress and thus avoid being obliged to secure such information in nonmedical publications. Often all the public, at least in France, knows is what it learns through advertisements of quacks in lay journals. There is much less restriction of this class of publicity here than in the United States. One charlatan in Paris treats all cases by pressure on the sympathetic nerve endings in the nose and his practice can well be envied by those who do not advertise. The public ought to be told that such extravagant claims are impossible to achieve but that the charlatan is profiting by the remarkable success of operations on the sympathetic nervous system by Leriche and other surgeons in France. The patient of the present day is no longer content with the explanations given by the medical man in the past. The higher up in the social and intellectual scale, the more questions are asked by the patient. In France there are journals such as *Guérir* (to cure) which appear weekly and attempt to diffuse knowledge concerning medical achievements, such as the progress made in the treatment of cancer, tuberculosis and heart disease. The articles treat these questions in the simplest nontechnical manner possible, but all criticism and reservations are omitted. The articles are well illustrated. The readers follow the fantastic descriptions as closely as they would an exciting novel, but they cannot distinguish what has been proved and accepted from that which is still in the nebulous stage.

Advice as to treatment can be had from these journals for the asking. This sort of publicity does more harm than good to the medical profession. Advertising campaigns for the use of particular methods have been begun by these lay journals and no one can prophesy how far such a campaign will lead. Massart believes that suppression of these lay publications is impossible. The only remedy is to have the medical profession publish a journal so that in an unselfish manner the duties and the difficulties of the profession can be pointed out. Such a journal should be as well illustrated as are the best of the nonmedical publications. The public should be kept abreast of discoveries in medicine, properly evaluated. The danger of improper and dishonest application by quacks of new methods of treatment must be pointed out. Massart believes his idea is new but evidently he does not know of the excellent work being done in this field by the American Medical Association.

Culture of Entire Thyroid Glands

At the June 26 meeting of the Academy of Sciences, Alexis Carrel and Charles A. Lindbergh made a report of experimental work by which an entire organ or region of the body may be transplanted into a sterile receptacle and through the automatic supplying of a nutrient fluid through the arteries of the organ the circulation may be maintained as under normal conditions. The survival of organs such as the thyroid and ovary has been followed by their development. Such complete visceral cultures is not meant to supplant tissue culture. It differs from the latter not only from the standpoint of technique but also in its objectives. Organ culture aims to study

associations of cells and not the latter alone. The complete organ culture is of aid in the observation of the elaboration *in vitro* of the secretions of endocrine glands, of the substances essential to their growth, of their functional activity, of the laws of association and, finally, of the treatment *in vitro* of organic and arterial diseases.

The method employed in the study of six thyroid glands of the cat and nine of the rooster was described in detail. Three culture mediums were utilized, blood serum more or less diluted, an artificial medium containing amino acids, and a third containing peptones. The circulation of the first two is accompanied by a diminution in the size of the glands, which, however, conserve their normal structure in part and the follicles remain filled with colloid substance even after twenty-one days of blood serum circulation. The glands undergo degenerative changes in a medium containing relatively high percentages of amino acids. The liquid the use of which is followed by the most marked growth of the thyroid is that containing peptones. In three or four days the gland doubles in size. From the histologic point of view one notes either epithelial proliferation with disappearance of colloid material or an increase in the size of the cells with production of colloid material. There can be no doubt that the gland continues to function, but the architecture, follicular structure and activity vary according to the chemical, physical and physicochemical composition of the fluid circulating through the vessels of the gland. This new method would seem to have important application in physiologic chemistry, pathology and clinical medicine.

Destruction of Rats in Warehouses

The destruction of rats has been studied for many years by Loir of Havre, because of the losses incurred as the result of the presence of rats in the warehouses of this port. At present, only poisons and viruses are employed in France. When a few rats have been killed the colony migrates, but it returns as soon as danger ceases. The majority of rats killed are males (131 out of 140 in one week), hence the reestablished colony does not diminish in number. Loir maintains that cats are the most efficacious agents against the rat menace in sea ports. It is unnecessary to attempt to breed a special rat catching cat. All that will take care of itself, because if the cats are protected and well fed they soon become powerful enough to attack rats. Loir did not belittle the value of bull terriers but thought their usefulness was lessened by the fact that the rats hear the noise made by dogs, whereas cats work much more quietly. The smaller the number of cats in a given space, the better the results. In Italy, when Mussolini ordered the drainage of the marshy regions near Rome, 3,000 cats were brought to destroy the rats so that they would not interfere with the raising of grain on the drained soil.

An Old Paris Hospital to Be Razed

A final gathering of notables in the Paris medical world was held in May at the Charité Hospital prior to turning it over to the contractors who are tearing the historic structure down. It will be replaced by laboratory buildings of the medical school. Thus disappears the first building in which courses in medicine were given in the eighteenth century. The hospital was founded in 1602 by a religious order, the Brothers of St. John, with the aid of Queen Marie of Medici, wife of Henry the Fourth. At that time Paris possessed only one other hospital, the Hotel Dieu. Buildings were added from time to time until in 1788 its capacity was 208 beds, arranged in large wards so that medical were separated from surgical cases.

The institution was particularly renowned for its lithotomists, especially Frère Jacques, who is shown in a painting dating back to 1697 surrounded by physicians and removing a vesical calculus through the perineal route. His mortality was so high that he was obliged to leave France.

Desault was a surgeon and Corvisart an internist at the Charité, when in 1789 they held clinics for the first time in French history.

Among other famous medical men who had services during the nineteenth century may be mentioned Potain and Lacnec.

The famous amphitheater in which Corvisart taught pathology has been visited by thousands of physicians from foreign countries.

The *Paris médical* devotes its August 3 issue to the history of this famous institution, and the illustrations show all the stages of its development and the part the Charité has played in French medicine.

Alcohol Injections of Phrenic Nerves in Bronchiectasis

At the May 10 meeting of the Société médicale des hopitaux, Chiray and Malinsky reported a case of cylindric dilatation of the bronchi with profuse purulent expectoration and high temperatures which did not improve during a month's stay in the hospital. Alcohol was then injected into the left and a few days later into the right phrenic nerve, to inhibit the movements of the corresponding halves of the diaphragm. The inhibition was verified by radioscopia. This treatment was followed by marked improvement in the amount of expectoration. Injection of the bronchi with iodized oil and subsequent radiography revealed bronchi of almost normal size. The patient can be considered clinically cured.

In the discussion, Rist stated that he had advocated phrenicectomy ten years previously for dilatation of the bronchi. He had some remarkable results. Rist has never been obliged to operate on both phrenic nerves.

Lereboullet reported a gratifying result in a boy of 9 with congenital bronchiectasis of the left lower lobe, profuse expectoration and clubbed fingers. The profuse expectoration ceased after a phrenicectomy, the diaphragm rising 4 cm. The fingers assumed their normal aspect rapidly. In other children, postural drainage, as advocated by Quincke, had been followed by marked improvement, hence operative treatment would be less often indicated in children.

Sergent believed that alcohol injections are preferable to phrenicectomy. He had never observed any benefit from phrenicectomy in chronic bronchiectases, but it was efficacious in cases following a bronchopneumonia with slow resolution. No single method can be considered as the choice in the treatment of bronchiectasis.

Recovery Following Mercuric Chloride Poisoning

Marchal, Soulie and Grupper reported a case of mercuric chloride poisoning with recovery at the April 12 meeting of the Société médicale des hopitaux. A woman of 28 swallowed 5 Gm of corrosive mercuric chloride dissolved in water. Three days later anuria appeared accompanied by a blood urea of 270 mg per hundred cubic centimeters, rising later to 535 mg. Following multiple transfusions of from 300 to 350 cc the anuria, which had lasted twelve days disappeared, the urinary output attaining as high as 3,500 cc. in twenty-four hours. The alkali reserve of the blood remained about normal throughout. The electrocardiographic changes included flattening of the T wave inversion of the latter and widening of the ST space, all of which indicated myocardial changes of a toxic character. The blood showed at the beginning a marked polymorphonuclear leukocytosis followed by a late aplastic anemia with progressive granulopenia as indicative of bone marrow involvement. The cardiac condition responded very well to digitalis in large doses. They believe that the blood transfusions and the frequent administration of salt solution to compensate for the loss of chlorides as shown by the blood examination are responsible for the favorable outcome.

Training School for Leaders in German Medicine

June 1, on a specially chosen area in a former village of Mecklenburg, in charming scenic surroundings, a training school for leaders (führer) in German medicine was opened with fitting ceremonies. According to the address of Dr. Wagner, the federal führer of the medical profession, the purpose of the school is "to open the mind of the future medical führer to the value and the blessings of the healing forces of nature and its elements. It is designed to help liberate him from the spirit of prejudice and dogmatic intolerance with which he may be inclined to view old school medicine, and to teach him to cooperate in a spirit of camaraderie with all those who, as his co-workers, are laboring to promote the cause of public health." In addition, candidates are expected to secure, through attendance on the organized courses, a knowledge of law, an intimate acquaintance with the mode of functioning of organized society, and a knowledge of the heredobiologic and racial principles governing the new policy of health culture in Germany. During the present summer about 600 local leaders connected with the public health service of the national-socialist party will receive special training in intensive fourteen day courses. Later on, six weeks' courses for the advanced training of a selected few will be organized.

Mortality from Circulatory Disorders

Disorders of circulation have been for some time the most frequent cause of death. In 1931 Germany's mortality from "diseases of the circulatory organs" and from cerebral hemorrhage amounted to 27.5 per 10,000 of population, which constituted 24.4 per cent of the total mortality. The mortality of diseases of the circulatory organs increases with the age of the patient. From about 1 death per 10,000 in childhood there is an increase to 400 per 10,000 in old age. Conclusions based on the statistics, Dr. Koller of the Kerckhoff Institute for Cardiac Research in Bad Nauheim brought out, are greatly impaired by their varying degree of reliability. More exact collection of statistics on the causes of death usually results in higher mortality rates for the diseases of the circulatory organs. Many cases of "senile weakness," if examined more in detail, would be found to be cases of circulatory disorder, while a somewhat smaller percentage of cases of "heart disease" might be more accurately diagnosed. In Saxony in 1922 about 89 per cent of all deaths ascribed to diseases of the circulatory organs were certified by physicians, as compared with only 81 per cent of the deaths due to all causes. With regard to infants, the reliability of the statistics on the causes of death was low, being estimated at 50 per cent. With the exception of the youngest age group deaths from diseases of the circulatory organs are certified with reasonable accuracy in the main.

Recent decades have brought a sharp increase in the mortality due to circulatory diseases. One of the main reasons for the increase is the upward shift in the average age of the population—the absolute and the relative increasing percentage of old persons. This explains only a part of the increase, for, in spite of the changes in the numerical representation of the older age groups the mortality in Prussia from 1905 to 1925 would have increased only to 22.3 for men and to 20.8 for women, and in Bavaria during the period from 1900-1901 to 1925, to 23.0 for men and to 24.0 for women. The actual increase, however, is much greater, so that only 88 and 44 per cent, respectively, of the increase in Prussia from 1905 to 1925, and 48 and 26 per cent, respectively, of the increase in Bavaria during this period may be explained by the shifting that has occurred in the population. The increase among the men is greater than

for the women. The difference is caused by the greater number of men who lost their lives in the World War, which increased the relative representation of the older age groups. Whether any other factors besides shifting in the relative representation of the age groups and improvements in diagnosis have contributed to the increased mortality from diseases of the circulatory organs appears doubtful.

While the mortality from diseases of the circulatory organs has increased in the older age groups, it shows a distinct decline in the younger and the middle groups. Here too an improvement in the quality of the statistics will play a part, chiefly through the turning over of a number of deaths to the brackets of various infectious diseases, as the fundamental disorders. It is quite possible that part of the reduction in mortality of the young is explainable by better therapeutic results. In infants, conditions are different. The improved classification of causes of death brought usually (particularly in Prussia) a marked decline in the figures for infants. In Bavaria however, the figures show an increase. The influence of the seasons on women is greater than on men. Persons of advanced age are more affected by the seasons than persons of the middle and the younger group. The course of the curve appears to justify the assumption that the increased mortality of the winter is due to the premature termination of a number of lives that would have continued only a few months longer at best and that the reduced mortality of the following summer is in the nature of a compensatory adjustment. If this assumption is true, a high winter peak would be followed by an exceptionally low summer mortality. A scrutiny of the statistics, however, revealed that, aside from the fact that the winter and the summer curves may reflect a common increase, the curves have no connection, the winter and the summer figures show a wide fluctuation independently of each other. The increased mortality of the winter does not therefore concern persons with an especially unfavorable prognosis. There appears to be no doubt that the winter's additional toll of diseases of the respiratory organs plays a part. It is well known that, associated with periods of influenza deaths from diseases of the circulatory organs show an immediate and marked increase. The greater menace to persons with disorders of the circulatory organs that accrues from the more frequent complications of winter does not however, explain entirely the seasonal differences. This is shown by a comparison of the weekly statistics of Germany's large cities for the winters of 1932-1933 and 1933-1934. In both years the winter peak for diseases of the circulatory organs reached a height hardly explainable by chance. In the winter of 1932-1933 the upward trend coincided with the wave of influenza. In the winter of 1933-1934, however, the influenza wave was not associated with any marked rise, so that other factors during this winter period must have influenced the high mortality from diseases of the circulatory organs.

Stomach Ulcer and the Kymogram

In roentgenologic examination of the stomach the use of the kymographic method is by no means a substitute for fluoroscopy or the ordinary film, as Cramer pointed out in a recent address before the Berlin Medical Society. Kymography, however, serves a special purpose—namely, the demonstration of a simple ulcer even though a tumor of the mucous membrane is absent. This is made possible owing to the fact that with the kymograph the functioning of the stomach, including the peristaltic waves, may be studied. Several important data have been discovered. Evacuation of the food from the stomach is not accomplished by peristalsis but rather by contraction of the stomach. During the contraction the food is pressed downward through the pylorus and upward toward the cardia. Likewise the lesser curvature executes peristaltic movements, although of a slighter degree. In the presence of an ulcer a typical manifestation is

the general hyperperistalsis of the whole stomach in contrast with the dynamic rigidity in the immediate vicinity of the ulcer. From this "aperistaltic" zone one can diagnose kymographically a simpler ulcer, also a bleeding ulcer. In extraventricular tumors, the kymogram was found useful also in establishing a differential diagnosis.

Medical Advisers in Shoe Establishments

For years, ethical German physicians have strongly deprecated the custom of large shoe establishments engaging physicians to serve as expert advisers to their customers in the purchase of suitable shoes. In this manner alleged orthopedic shoes were disposed of that did not meet the requirements of orthopedists. The medical court of honor for the Berlin district has now rendered a decision to the effect that physicians are prohibited from serving as medical advisers in shoe establishments. The physicians who have been serving in that capacity have been notified that they must terminate their contracts with shoe firms at the earliest possible moment. All physicians working under such contracts who do not announce within a few days their compliance with the law will be reported to the court of honor.

Industrial Accidents in 1933

Government authorities and private organizations are constantly calling attention to the menace of industrial accidents. In the official *Nachrichten für Reichsversicherung*, statistics were recently published showing that in 1933 in the industrial plants included in the 'gewerbliche Berufsgenossenschaften' 427,688 accidents occurred, 2,402 of which resulted fatally. In 1932 there were 461,682 industrial accidents, 2,311 of which proved fatal. The increase is due chiefly to the fact that the number of plants rose from 1,124,848 in 1932 to 1,145,026 in 1933, while the number of persons insured mounted from 8,280,075 in 1932 to 8,977,155 in 1933. As compared with 1913, the number of industrial accidents was 53,523, or 9.21 per cent lower while the number of insured was 15.5 per cent less. The maximal number of industrial accidents during recent years occurred in 1928, there having been 1,046,112 accidents with 5,252 fatalities.

Although the number of accidents compared with 1932 shows an increase, which is due to a great extent to the enrolment of a large number of unskilled workmen, it may be noted that the number of persons receiving accident compensation for the first time has declined by 4,554, or 14.37 per cent. Without doubt this good showing is the immediate result of accident prevention propaganda.

Decline in Suicide Rate

The statistical bureau of the city of Berlin has published a series of statistics on suicide in Berlin in relation to unemployment, during the decade 1925-1934. An examination reveals that the two curves show a surprising resemblance. When the unemployment increases the suicides increase although not to the same extent. When, during the years 1925 and 1926, the number of unemployed mounted rapidly (from 81,000 to 275,000), the suicides increased from 1,587 to 1,779. In 1927, when the unemployed in Berlin dropped to 209,000, the suicides declined to 1,687. The same observation was made in 1928, the number of unemployed numbering 183,000 and the number of suicides 1,481. Since 1928 unemployment has increased steadily and likewise the number of suicides. In 1932 the maximum was reached, the statistics showing 635,000 unemployed and 2,262 suicides. In 1933 the number of unemployed dropped to 611,000 and at the same time (and in almost the same proportion) the number of suicides fell to 2,136. In 1934 there were 417,000 unemployed and 1,811 suicides. As former observations have shown it is evident that the suicide rate is strongly influenced by economic conditions.

International Congress of Hospitals

The fourth International Congress of Hospitals, organized by a committee on which the Spanish prefect served as chairman, was held recently in Rome. The first topic, which was covered by four speakers, was "The Hospital from the Standpoint of Public Health."

The first speaker, Professor Ronzani, director of the Hygienic Institute of the University of Milan, developed the subject from the point of view of general hygiene and demonstrated the need of coordinating the existing hospitals, by province or region, with relation to their equipment. He proposed the creation of provincial committees, whose duty it would be to coordinate the hospitals and promote the construction of new hospitals or the reorganization of existing institutions in accordance with the technical and hygienic standards established by the ministry having jurisdiction. In every hospital should be established consultation centers for the early diagnosis of disease and for the treatment of patients dismissed from the hospital proper. The program would be completed by the creation of professional schools for nurses and for hospital social workers. The latter would serve as mediators between the physicians, the welfare organizations, the insurance companies and other bureaus.

The second speaker, Dr. Browne of Scotland, treated the problem from the point of view of social hygiene and political economy. He emphasized that the constantly increasing number of patients makes necessary an increase in hospital services, which might become effective centers of public hygiene. The difficulties in the way of improvement in hospital services are due to the lack of a rational classification of patients, to defects of construction and equipment, and to an inadequate personnel.

The third speaker, Professor Rüdin of Germany, discussed the eugenic problem, pointing out that the activities of the hospitals in this field must be controlled by the central government, and that hence it is necessary for hospital physicians to know the scientific bases of eugenics, which is founded on the preservation of the health of the race, which includes protection against hereditary taints. The hospitals may render useful service by publishing detailed statements on hereditary diseases.

Hospital physicians should not confine themselves to collecting information on the patient but should extend their investigations to the members of his family.

The fourth speaker, Professor Sarraz-Bournet of France, took up the administrative side, and contended that the hospital should not be solely an institution for the treatment of patients but should also participate in social work, introducing, among other things, courses in sanitary instruction.

The second topic, "The Organization and the Technical Installations of Hospitals," was discussed by speakers representing respectively the United States, Poland and Switzerland. The first speaker, Schwittalla, spoke on the coordination of hospital activities to improve the quality of the aid rendered patients and expressed his regret that at present there are too many organizations in this field, while a fixed purpose is lacking. The work of the physicians, the nurses, the administrators and the various welfare organizations should be subordinated to the chief aim of the hospital—namely, furnishing the patient with the best care possible.

The second speaker, Professor Mogilnicki, spoke on the economic principles that should govern the technical organization of a hospital, emphasizing that all luxury should be suppressed and only those things done that improve the quality of the services.

Professor Van der Leen of the Netherlands explained a system of bookkeeping especially applicable to hospitals.

The question of eugenic sterilization was then taken up and gave rise to animated discussions. Dr. Schultze of Germany emphasized that the modern hospital, in addition to the positive task of restoring the patient to health and strength, must assume also a negative task, which consists in depriving of procreative power such patients as are affected with hereditary taints. In the opinion of the speaker, the regulations at present in force in Germany will be adopted by all civilized countries. This view was frankly opposed by Dr. Doherty of Ireland and Dr. Groonenberg of Amsterdam, who protested in the name of the Netherlands delegation. Likewise Professor Lepine of France declared that the problems of eugenics and of sterilization should be banished from congresses on hospital management, since the duty of the hospital is to promote the treatment of sick persons.

Tuberculosis of the Bones and Joints

Under the chairmanship of Professor Putti the second congress for the study of osteo-articular tuberculosis was held recently. The first topic was "Internal Localizations of Osteo-Articular Tuberculosis in the Child." The opening paper was presented by Professor Frontali, who emphasized that osteoarthropathy in the child is due in 84 per cent of the cases not to bovine tubercle bacilli, as has been contended by some, but to human bacilli, the first localizations of which are commonly found in the respiratory system. The speaker held that the diffusion of the tuberculous virus takes place from foci—usually intrathoracic—by way of the blood, giving rise to localizations also in the skin, which are frequent in children with osteo-articular involvement. Contrary to the general belief, children affected with tuberculous osteoarthropathy may spread contagion among children with whom they associate, because of localizations in the respiratory tract that are often overlooked. Sometimes the pulmonary focus exerts a decisive influence on the outcome of the orthopedic treatment. He opposed the conception of Marfan that osteo-articular tuberculosis furnishes increased resistance to pulmonary infection and demonstrated that tuberculous spondylitis, for example, gives rise to mechanical conditions that favor the evolution of pulmonary disorders.

The second topic was "Radiodiagnosis of Osteo-Articular Tuberculosis," which was opened with a paper by Professor Zanoli. He considered atrophy, which is neither characteristic nor constant in tuberculosis. In fact many other pathologic conditions are associated with atrophy. Osteosclerosis and osteophytic growths are more frequent than is supposed. The age of the patient is important in explaining the diverse behavior. Periostitis ossificans and diaphyseal localizations are characteristic of early years. The destructive phenomena are more frequent in the child than in aged persons, in whom the lesions are more circumscribed. There are diagnostic difficulties, for example, the radiographic interpretation of a cervical lesion is difficult, since, in the majority of cases, the more positive the roentgenogram is, the more certain it is a lesion in a reparative stage. The observations are uncertain also in sacrocoxitis which becomes manifest only when there are extensive lesions. The same may be said of costal and sternal caries. In tibiotarsal tuberculosis the evolution is similar to that observed in the knee. It is not clear why tuberculosis of the hip manifests itself nearly always in the form of destructive phenomena whereas in the knee and in the foot these are much less frequent. In general, the pathologic condition revealed by the roentgenogram appears to be less than it really is. Furthermore, roentgenograms are negative with respect to abscesses, except mediastinal, calcareous and occasionally psoas abscesses. Finally, diagnostic difficulties arise in the differentiation of syphilis from osteomyelitis. While the speaker admits that radiology has great merits, he concludes that the patient must be studied and judged chiefly by clinical aids.

Verdina spoke on the value of Meinicke's new serodiagnostic test for tuberculosis. The test is technically and biologically

similar to that proposed for syphilis, by the same author. In a series of 205 cases, the speaker secured only negative reactions in healthy persons. In persons known to be tuberculous he obtained 85 per cent of positive, 13 per cent of doubtful and 2 per cent of negative results.

Treatment of Cutaneous American Leishmaniasis with Sodium Arsenite

Dr. Aguiar Pupo, director of the department of skin diseases of Santa Casa, a hospital for women in São Paulo, recently read, before the Sociedade de Medicina e Cirurgia of São Paulo, a preliminary report on the results of the injections of sodium arsenite in the treatment of cutaneous American leishmaniasis. The author has obtained satisfactory results, from January of the present year up to now, from the injections of sodium arsenite, prepared by the following formula:

Arsenic trioxide	
Neutral sodium carbonate	0.25 Gm
Sodium chloride	2.00 Gm
Distilled water	250 cc

The solution is placed in ampules of 2 cc and 5 cc capacity and sterilized. A cubic centimeter of the solution contains a milligram of sodium arsenite. The injections are given twice a week intramuscularly, beginning with 2 cc and increasing it after the first two weeks until 5 cc at each injection is reached. Improvement of the ulcerations is noticeable after the second week of treatment. By the end of the treatment, which lasts for thirty or forty-five days, the ulcers as a rule are entirely healed. The injections are well tolerated by the patients. The pain during the injection is slight and no local inflammatory reaction occurs. Some patients react with stomachache or headache, which lasts all the first day. The reaction is controlled either by reducing the dose or by increasing the interval between the injections. The treatment, in comparison with the administration of antimony and arsenical preparations, has the advantages of the use of sodium arsenite, a drug accepted by the international pharmacopeias, the simple technic for preparation and administration of the injections and the moderate expense. The specific action of arsenic trioxide and of its alkaline salts on certain organisms is proved by the results reported in the treatment of experimental trypanosomiasis, of cutaneous American leishmaniasis reported by the speaker, and of malaria, previously reported by Slevogt and Fricke of Germany (1700-1710), by Fowler, Frei, Wilan and Pearson of England (1786), by Boudin of France (1842) and more recently by Brera, Tommasi, Crudelli and Richi of Italy.

Encephalography in Schizophrenia

Drs. Fausto Guerner, J. Fajard, M. Jahn and Celso P. da Silva in a lecture recently delivered before the Sociedade de Medicina e Cirurgia of São Paulo reported the results of suboccipital injections of air in the treatment of schizophrenia at Juquery Hospital. The work of the speakers was based on that previously reported by Jacob and Jinkler, Jacobi, Moore, Nathan, Elliott and Laubach Foster. The age of the patients, four women and four men, ranged between 19 and 52. In the majority of the patients the mental condition was not complicated by any other disease. The mental disturbance had developed long before in two patients, recently in one, and it had been of moderate duration in five. The quantity of cerebrospinal fluid removed, prior to the injection of air, was 45, 80, 90, 110, 110, 125, 130 and 140 cc. The quantity of air injected was equal to that of cerebrospinal fluid removed in three cases and from 10 to 15 cc. less than that in five cases. For the

interpretation of the results the criterion established by the American Committee for Standardization of Encephalographies was followed, that is, the comparison of the encephalograms of schizophrenic patients with those obtained from patients with other diseases and from normal persons. The speakers conclude that the presence of atrophy of the frontoparieto-occipital zone of the cerebral cortex was detected by encephalography in a group of eight schizophrenic patients, intense in seven and moderate in one. The frontoparieto-occipital zone and more intensely the upper parietal lobulus were involved in cases of intense atrophy. Only the upper parietal lobulus was involved in the cases of moderate atrophy. There was ventricular dilatation in three cases, intense in two and moderate in one. The size of the cisterna basalis was much increased in three cases and moderately increased in two. The most advanced pathologic changes were seen in the two cases in which the disease had developed long before. Cortical atrophy was seen even in the case of more recent development, about one year, during a remission of the condition.

Virus in Trachomatous Tissue

Dr. A. Busacca recently reported to the Sociedade de Biologia of São Paulo that he obtained the development of trachomatous nodules in the choroids and the ciliary body of rabbits and chickens by the inoculation of fragments of tissues from human trachomatous eyes that have been kept in the icebox in 50 per cent glycerin from eight or fifteen days and then inoculated in the vitreous body of the animals. The material from the trachomatous nodules of the eyes of the animals was kept in glycerin for five days and then inoculated in the vitreous body of rabbits and chickens in a new lot, in order to obtain serial transmission of the virus. The development of trachomatous nodules has been proved by the histologic examination of the eyes of the animals up to the second serial transmission. The period of development of the nodules is about forty-five days after the inoculation of trachomatous tissues.

Measures to Combat Tuberculosis

The board of health is making efforts to combat tuberculosis under a ten-year plan. The first thing is to establish a "health center" in every city and town. At present there are only 115 health centers in the country. Practitioners will be obliged to report to this center the names and addresses and other necessary data about patients with tuberculosis. This compulsory report to the authorities was at first opposed by physicians on the ground of professional secrecy. The health center, however, will be in charge of medical officers, consequently, the patients' data will always be kept among physicians. The center will chiefly work for the early examination of suspects and the prevention of tuberculosis. The physicians at the center will first cooperate with the primary school teachers in finding tuberculous school children.

On the other hand, the board of health will soon give orders to schools, factories, dormitories, theaters, department stores and buildings where numbers of people assemble to the effect that they should have more sanitary equipment for combating this disease. Indigent patients and members of their families will be given aid.

The sickness insurance, which is also under the control of the home office, has decided to give a physical examination to any applicant from any factory that has joined the sickness insurance. At least twice a year, all employees will be examined. The panel physicians are required to report every person sick with tuberculosis.

One of the most urgent needs is to spread knowledge of the danger of tuberculosis among the people. The board is planning to hold an exposition in every large city.

The war office, which is obliged to invalid out of the army any tuberculous soldier, is reported to have planned a new measure to solve its problem. It will help the families of the invalided soldiers with money if possible.

The education office has put its hand to combating tuberculosis in teachers in primary schools. The new plan is to have a sanatorium in each of the fifty-six prefectures within the coming ten years. The initial expenses will be paid in part by the government and in part by the mutual aid association of the teachers organized in every locality, the rest will be paid by the local government. The cost of administration will be paid by the local government and by the association. In some prefectures this system is already working on a small scale.

Annual Examination of Primary School Children in Tokyo

The physical examination of all school children in the capital was recently done for this year. Those examined comprised 344,448 boys and 332,139 girls between 7 and 15 years of age in the primary schools, 56,710 children were found to be near sighted and 2,135 astigmatic, 26,964 suffered from trachoma and 5,756 from color-blindness, 3,585 children had some defects of hearing. Those who had inflammation or enlargement of the cervical glands amounted to 28,413, enlarged tonsils 132,768 and favus 35,064.

Dr Kanasugi Honored

The celebration of Dr Eigoro Kanasugi's seventieth birthday took place June 22 in Tokyo under the auspices of the Japan Medical Association. He is a member of the house of peers and an influential politician as well as an expert nose and throat specialist with a large hospital in Tokyo. On this occasion more than 600 prominent personages were present, including the prime minister and three other cabinet ministers. It was the most successful meeting held in several years. He was given an offering of 10,000 yen collected from the members of the Japan Medical Association in recognition of his services to medicine in this country and to the public. A bronze bust will be erected in front of the office of the association. He declared that he would retire from medical practice and politics, although he is now greatly needed when medicine has many important questions to be solved. He will remain as the president of the Jikei Medical College.

Prostitution in Japan

The unlicensed prostitutes throughout the country who were arrested in 1933 on the charge of being a social menace numbered 6,642, and numerous others escaped arrest. Of these, 6,374 were examined and 223 were found to be suffering from syphilis, 903 from gonorrhea, 209 from soft chancre and 134 from other venereal diseases. Of the licensed prostitutes, 49,302 were distributed among 509 licensed quarters, under the charge of 10,281 brothel keepers. The number of pleasure seekers who visited those prostitutes in 1933 was 24,922,504, a great increase as compared with previous years. The 'geisha girls,' who play the part of bar-maid, singer, waitress and sometimes prostitute if required, though unlicensed numbered 74,200 throughout the country in 1933. Their numbers are decreasing considerably, owing to the rapid increase of waitresses, but they are more or less a source of venereal diseases.

While the abolition of licensed prostitutes will be carried out in the near future as declared by the government the prevention of venereal diseases will remain a great social problem, in view of the unlicensed prostitutes. The delay in abolishing the licensed prostitute is due in part to this problem of the unlicensed prostitute.

MOSCOW

(From Our Regular Correspondent)

Aug 17, 1935

The Congress of Surgeons

The twenty-third All Union Congress of Surgeons was held in Leningrad June 25-30. Prof Nicolas N Bourdenko of Moscow read a paper on shock, which he considers the sum of reactions to different insults. Experimental shock can be studied in animals. Postoperative shock is much more amenable to study. The diminution of blood circulating in the vessels (as the result of operative intervention) gives a fall of venous pressure and a respective laxity of the work of the right side of the heart. Curative measures must aim at stimulating the vessel-moving center to augment the total mass of blood taking part in the circulation. In cases of grave losses of blood, transfusion must be used.

A L Polenov of Leningrad reported the results of 200 extirpations of cerebral tumors. Prof Jacob M Brouskin of Moscow spoke on the organization of anticancer campaigns. About 5,000 cancer patients were hospitalized in the Leningrad Oncologic Institute and twenty city hospitals in the last nine years. This number includes 2,937 cases of cancer of the stomach, 1,249 of the mammary glands, 337 of the rectum, sixty-two of the mouth and 422 of the lip. The third topic of the congress was abscess and gangrene of the lungs. Prof Serge I Spasocuczyk analyzed 312 cases of this disease that he observed at Moscow in the last eight years. Abscess and gangrene of the lungs were four times more frequent in men than in women. The fourth program topic of the congress was devoted to the evacuation of injured soldiers in military operations. There was read a series of reports by physicians from the Military Medical Academy, about the type of surgical work to be done at different stages of evacuation. The last program reports were devoted to pseudarthrosis. Papers were read by Professors Tourner, Sitenko and Chaklin. The next All-Union Surgical Congress will be held at Moscow in 1937.

The Kazan State Institute

On April 23, 1920, in Kazan, the Clinical Institute for Graduation of Physicians was opened. During the last fifteen years the institute has graduated more than 5,700 physicians. In 1934 the number of graduates was 1,073. A special group of student-managers of district health departments is taught how to organize soviet health care. They study organization, the planning of health care, medical economics, and so on. During the last fifteen years the institute has produced twenty-five professors, thirty-three dozenten and 211 assistants. The scientific research work of the institute is closely connected with its practical work. It has resulted in about 2,000 publications printed in the "volumes" of the institute, in the *Kazan Medical Journal* and other medical journals of the Soviet Union and foreign countries. About 10,000 patients are admitted every year by the clinics of the institute. All graduate students in the institute receive a scholarship which equals the salary they obtained when they are on duty. In many towns, especially university centers, institutes for graduation of physicians, as in Kazan, are formed.

Marriage and Divorce

The principal difference between soviet and capitalist legislation on marriage and divorce is that this important act can be done in our country without difficulties of a juridical or religious character. Marriage and divorce in the Soviet Union are much easier than in other countries, yet the population looks upon marriage with gravity. The Central Institute of Mother and Child Care studied 2,000 families of workers at Moscow. The results obtained by the institute are of interest. Before the October revolution, 78 per cent of women married

at an age younger than 20 years and 15.3 per cent married between 21 and 24. After the revolution the corresponding data are 44.4 and 36.6 per cent. The higher level of matrimonial age shows more seriousness about the question of family building. Of the prerevolutionary marriages, 53.9 per cent occurred after one month of acquaintance and 16.5 per cent after three to twelve months. At present the corresponding figure is 20.7 per cent and, after a six months acquaintance, 55.7 per cent. These data show that at present more discretion is observed in contracting a marriage. The number of divorces is higher than before the revolution. The initiative in divorces is taken mostly by the women. These figures show that soviet legislation helps to build a family on a more solid foundation than before the revolution.

The International Congress of Physiologists

The fifteenth International Congress of Physiologists was opened August 9 at Leningrad in the former state duma hall under the presidency of Prof. Ivan Petrovitch Pavlov. About 1,500 delegates from thirty-seven countries were present at the congress, the United States and Great Britain being represented by a delegation of 297 members. Three hundred and six papers were read by foreign guests and 169 by soviet scientists. Twenty-two scientific films were demonstrated. In the laboratories of the military medical academy twenty-four different experiments were demonstrated.

The congress was greeted at the opening meeting by the secretary of the Central Executive Committee of the Union of Socialist Soviet Republics, by the People's Commissar of Health, Kaminsky, and by others. The halls where the meetings of the congress were held have loud speakers arranged so it is possible to hear all the papers simultaneously in five languages—English, Russian, French, German and Italian.

In their leisure time, the delegates visited the town and suburbs, laboratories, clinics and scientific establishments, in particular Pavlov's laboratories at Coltush near Leningrad. The last plenary meeting of the congress was held at Moscow, August 17. In following letters will be given a report on the scientific work of the congress.

Marriages

CHARLES ROY HOSKINS JR. to Miss Virginia Eubank Segar, both of Saluda, Va., at Washington, D. C., July 1.

THEODORE F. HAMMERMEISTER, New Ulm, Minn., to Mrs. Pearl L. Rexford of Minneapolis, recently.

HUGH M. C. LINDER, Clifton Springs, N. Y., to Miss Eleanor Shelton of Nashville, Tenn., June 15.

RICHARD H. KIENE, Concordia, Kan., to Miss Edith Elizabeth Swing of Bryn Mawr, Pa., June 8.

ALFRED J. SILBIGER, Randolph, Ohio, to Miss Evelyn Cheswick of East Cleveland, June 16.

HAROLD J. KULLMAN, Detroit, to Miss Edna Mary Warner at Cheboygan, Mich., July 13.

ARTHUR B. RICHTER, Flora, Ind., to Miss Lyda Mary Fisher of Steubenville, Ohio, May 7.

SAMUEL R. KAUFMAN to Miss Martha Davidow, both of Wilkes-Barre, Pa., May 2.

NATHAN W. RUBIN to Miss Dorothy M. Moyer, both of Norristown, Pa., April 28.

ROBERT I. MCPHAIL to Miss Helen Bernice Ebersole, both of Arcadia, Ohio, May 10.

GEORGE E. MCGINNIS to Miss Margaret Dager, both of Norristown, Pa., May 4.

ALBERT HAROLD KEEFER, Marquette, Mich., to Miss Ruth Doolittle, June 27.

ADOLPH ALLAN SMOLEN to Miss Mildred Gerber, both of Chicago, July 7.

RUBIN M. LEWIS to Mrs. Elsie Finn, both of Philadelphia, May 21.

Deaths

Edwin P. Sloan, M.D., since 1932 a member of the Judicial Council of the American Medical Association and from 1924 to 1932 a member of the House of Delegates, died, September 13, at his home in Bloomington, Ill., of myocarditis. Dr. Sloan was born in Neosho, Mo., Feb. 13, 1878. He received his medical degree from the University Medical College of Kansas City (Mo.) in 1898 and later studied in Berne, Switzerland, and took graduate work at the University of Berlin, Chicago Polyclinic and the New York Post-Graduate Medical School. From 1898 to 1903 he practiced in Danvers, Ill. In 1905 he settled in Bloomington, where he specialized in the surgical treatment of goiter and diseases of the stomach. He was a founder of the American Association for the Study of Goiter and a former president of that organization. He was a founder also of the International Conference on Goiter in Berne, Switzerland, and several times served as a delegate. He was a member of the American Association of Obstetricians, Gynecologists and Abdominal Surgeons, past president of the Illinois State Medical Society, and past chairman of the advisory board of the Illinois Department of Public Health. Dr. Sloan was surgeon-in-chief of the Sloan Clinic and on the staffs of the Menonite Hospital and St. Joseph's Hospital. He had written many articles on goiter, abdominal surgery and gynecology and had practically completed the writing of a textbook at the time of his death.

Charles Norris, M.D., New York, College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1892, since 1918 chief medical examiner of New York, professor of forensic medicine, New York University College of Medicine, formerly instructor of pathology and assistant in bacteriology and hygiene at his alma mater, and instructor in pathology of infectious diseases, Cornell University Medical College, member of the American Association of Pathologists and Bacteriologists and the American Society of Clinical Pathologists, director of laboratories at Bellevue Hospital, 1904-1918, was decorated *Chevalier de la Couronne*, Belgium, in 1934 was awarded the gold medal of the New York Academy of Medicine for distinguished service in medicine was widely known as an expert on medical jurisprudence and was instrumental in the solution of a number of notorious medicolegal cases, aged 67, died, September 11, of coronary sclerosis.

Ross McPherson, M.D., New York, Harvard University Medical School, Boston, 1902, member of the Massachusetts Medical Society and the American Association of Obstetricians, Gynecologists and Abdominal Surgeons, fellow of the American College of Surgeons, professor of gynecology and obstetrics, New York Polyclinic Medical School and Hospital, on the staffs of the United Hospital, Port Chester, Caledonian Hospital, Brooklyn, Dobbs Ferry (N. Y.) Hospital, Long Beach (N. Y.) Hospital, John T. Mather Memorial Hospital, Port Jefferson, N. Y., Hackensack (N. J.) Hospital and the Holy Name Hospital, Teaneck, N. J., aged 59, died, August 16, of cerebral hemorrhage.

William Walter Lewis, M.D., St. Paul, University of Minnesota Medical School, Minneapolis, 1902, assistant professor of ophthalmology, otology, laryngology and rhinology at his alma mater, member of the American Academy of Ophthalmology and Oto-Laryngology, past president of the Minnesota Academy of Ophthalmology and Oto-Laryngology, fellow of the American College of Surgeons, served during the World War, on the staffs of the Charles T. Miller Hospital, St. Luke's Hospital, St. Joseph's Hospital and the Children's Hospital, aged 59, was found dead in the Mississippi River, July 29.

John Alexander MacIsaac, New York, Harvard University Medical School, Boston, 1896, member of the Medical Society of the State of New York, served during the World War, at one time acting assistant surgeon lieutenant, with rank of junior grade, in the U. S. Navy, fellow of the American College of Surgeons, instructor in otorhinolaryngology, University of Bellevue Hospital Medical College, on the staffs of the Children's Hospital and the New York Eye and Ear Infirmary, aged 61, died, August 16.

Robert Douglas Roller Jr., M.D., Charleston, W. Va., University College of Medicine, Richmond, Va., 1905, fellow of the American College of Physicians, served during the World War, past president of the Kanawha County Medical Society, medical director of the Hillcrest Sanatorium, on the staffs of the Charleston General Hospital and St. Francis Hospital, consultant to the Veterans Administration, aged 56, was killed, August 10, in an automobile accident.

Charles Willard Selover \oplus Canandaigua N Y, University of Buffalo School of Medicine, 1904, past president of the Ontario County Medical Society, served during the World War, medical director of the Oak Mount Sanatorium, Holcomb, on the staffs of the Veterans Administration Facility and the Frederick Ferris Thompson Hospital, aged 53, died, July 26, in the Clifton Springs (N Y) Sanitarium of heart disease

William Graves Phillips, Maysville Ky, Jefferson Medical College of Philadelphia, 1909, member of the Kentucky State Medical Association, past president of the Mason County Medical Society, fellow of the American College of Surgeons on the staff of the Hayswood Hospital, aged 52, died, July 5, in the Jewish Hospital, Cincinnati, of tumor of the brain

Abram Whittemore Mitchell \oplus Epping N H, University of the City of New York Medical Department, 1887, councilor of the Rockingham County Medical Society, past president of the New Hampshire Medical Society, at one time member of the state legislature, aged 73, died, July 31, in the Elliot Hospital, Manchester, following an operation for appendicitis

Milo Melville MacKellar, Loveland Okla., College of Physicians and Surgeons Keokuk Iowa, 1896, past president of the Tillman County Medical Society, director of schools on the staff of the Frederick (Okla.) Clinic Hospital, aged 61, died, August 18, in St. Mary's Hospital, Rochester Minn., following an operation for glioblastoma multiforme

Edwin Ellsworth Brophy, Meadville Pa, Western Pennsylvania Medical College Pittsburgh, 1907, member of the Medical Society of the State of Pennsylvania, served during the World War, formerly on the staff of the Meadville City Hospital, aged 62, died, July 26, of Parkinson's disease and coronary thrombosis

Roy Fallas Mills \oplus Kansas City, Mo., Rush Medical College, Chicago, 1912, associate in medicine, University of Kansas School of Medicine Kansas City, Kan., served during the World War, aged 55, on the staffs of the Kansas City General Hospital and the Bell Memorial Hospital, where he died, July 18, of endocarditis

Frank Amos Crosby \oplus Lockport, N Y, Niagara University Medical Department, Buffalo, 1896, past president of the Medical Society of the County of Niagara, formerly member of the board of education, on the staff of the Lockport City Hospital, aged 63, died, July 13, of heart disease and nephritis

Thomas Holmes Middlebro, Owen Sound Ont., Canada, University of Toronto Faculty of Medicine, 1892, M R C S England L R C P, London, 1899 and F R C S, England, 1900, fellow of the American College of Surgeons on the staff of the Owen Sound General Hospital, aged 70, died, July 16

John Mason Morris \oplus Louisville, Ky, University of Louisville Medical Department, 1887, fellow of the American College of Physicians, aged 74, on the staffs of St. Anthony's Hospital and the Kentucky Baptist Hospital, where he died, July 21, as the result of injuries received in an automobile accident

Balrd Urquhart Brooks, Durham, N C, University of Maryland School of Medicine Baltimore, 1905, member of the Medical Society of the State of North Carolina, served during the World War, aged 54, on the staffs of the Lincoln Hospital and the Watts Hospital, where he died, August 24

John Walter McMahan \oplus Alma, Ga., Tennessee Medical College, Knoxville 1900, at one time member of the state legislature of Tennessee and state senator, health officer of Alma, and formerly health officer of Alcoa, Tenn., aged 59, died, July 30, in a hospital at Waycross

Herman Martinson \oplus New York, Columbia University College of Physicians and Surgeons New York 1915, served during the World War, on the staff of the Sydenham Hospital, aged 44, died, August 19, in the Mount Sinai Hospital, of acute hepatitis and jejunal necrosis

John Briggs Hagey, De Kalb Ill., University of Louisville (Ky.) Medical Department, 1902, member of the Illinois State Medical Society, past president and secretary of the De Kalb County Medical Society, city health officer, aged 65, died, July 29, of cerebral hemorrhage

Louis Anthony Carlet, Washington Pa, Jefferson Medical College of Philadelphia 1924, member of the Medical Society of the State of Pennsylvania, on the staff of the Washington Hospital, aged 35, died, July 14, in Philadelphia of congenital polycystic kidney

Henry B Gaynor, Polk, Pa., Temple University School of Medicine Philadelphia, 1910, member of the American Psychiatric Association, clinical director of the Poll State Hospital, aged 65, died, July 21, in the Jeanes Hospital, Philadelphia, of malignancy of the bladder

Roderick Frederick McHugh \oplus Aitken, Minn., Milwaukee Medical College 1912, formerly mayor of Aitken, on the staff of the Beecroft Hospital, served during the World War, aged 45, died, July 31, in St. Joseph's Hospital, Brainerd, of a gunshot wound of the chest

Edward J. Dougher, Midland, Mich., Baltimore University School of Medicine, 1898, member of the Michigan State Medical Society, secretary of the Midland County Medical Society, aged 71, died, July 26, in the Mercy Hospital, Bay City, of carcinoma of the colon

William Harris, Mystic Iowa, Milwaukee Medical College, 1912, member of the Iowa State Medical Society, served during the World War on the staff of St. Joseph's Hospital, Centerville, aged 49, died, July 17, of heart disease and cerebral hemorrhage

William Joseph Condon, New Brunswick N J, Medico-Chirurgical College of Philadelphia 1899, member of the Medical Society of New Jersey, served during the World War, aged 56, on the staff of St. Peter's Hospital, where he died, August 2

Joseph Edward Windbiel \oplus Amsterdam, N Y, Albany (N Y) Medical College, 1908, served during the World War, on the staffs of St. Mary's Hospital and the City Hospital, aged 49, died suddenly, July 21, of acute dilatation of the heart

Samuel Townsend Cousins, Wetumpka, Ala., Birmingham Medical College 1910, member of the Medical Association of the State of Alabama, aged 49, died, June 21, in St. Margaret's Hospital, Montgomery, of coronary occlusion

Frank Herman Mohrman \oplus Cleveland, Cleveland College of Physicians and Surgeons Medical Department Ohio Wesleyan University, 1910, on the staff of St. Luke's Hospital, aged 48, died, August 2, of coronary thrombosis

George Norton Miller \oplus New York, Harvard University Medical School, Boston, 1882, aged 78, died, July 30, in the Vassar Brothers Hospital, Poughkeepsie, N Y, of injuries received in an automobile accident

Elihu P. Easley, New Albany, Ind., University of Louisville (Ky.) Medical Department, 1872, member of the Indiana State Medical Association, formerly member of the city council, aged 87, died, August 2, of bronchitis

William C. Griffin, Cartersville, Ga., University of Nashville (Tenn.) Medical Department 1878, member of the Medical Association of Georgia, aged 80, died, July 23, of chronic nephritis and uremia

Benedict F. Shanahan \oplus Chicago, Bennett College of Eclectic Medicine and Surgery, Chicago 1897, on the staff of the University Hospital, aged 63, died, August 2, in St. Luke's Hospital of uremia

Willis Le Baron Hale, North Attleboro, Mass., Jefferson Medical College of Philadelphia, 1901, served during the World War, aged 58, died suddenly, August 11, of chronic myocarditis and nephritis

Kenneth Marvin Adams, Gouverneur, N Y, Syracuse University College of Medicine, 1931, aged 30, on the staff of the Stephen B. Van Duzee Hospital, where he died, July 26, of pneumonia

Cornelius B. Durham, Pineville, La., Memphis (Tenn.) Hospital Medical College 1912, member of the Louisiana State Medical Society, aged 49, died, June 30, in the Baptist Hospital, Alexandria

Henry Laurence Shively, New York, College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1888, aged 71, died, August 10, of cerebral hemorrhage

Samuel Bernstein, Detroit, University of Oklahoma School of Medicine, Oklahoma City, 1916, aged 51, died, July 28, at Dunnville Ont. of injuries received in an automobile accident

Arthur Dunning Mansfield, Baltimore, University of Maryland School of Medicine Baltimore, 1890, aged 67, died, July 27, of cerebral hemorrhage, arteriosclerosis and hypertension

Samuel Ernest Parrott, Cordova, Tenn., Memphis Hospital Medical College, 1901, aged 61, died, July 2, in the Methodist Hospital, Memphis, following an operation for appendicitis

Henry Hiram Fuller, Hillsboro, Texas, (registered by Texas State Board of Medical Examiners under the Act of 1907), aged 68, died, July 25, of carcinoma of the face

Adam Sharpe Gibson, Craik, Sask., Canada, Queen's University Faculty of Medicine Kingston, Ont., Canada 1912, aged 54, was killed, June 27, in an automobile accident

William Holmes Ross ♂ Patchogue, N. Y., Columbia University College of Physicians and Surgeons, New York, 1904, aged 54, died, September 3, of coronary thrombosis

Arthur Ward Bowles, Detroit, University of Nebraska College of Medicine, Omaha, 1932, on the staffs of the Grace and Receiving hospitals, aged 26, was found dead, July 30

John Warren Gard, Genoa, N. Y., Albany (N. Y.) Medical College, 1914, health officer of the towns of Genoa, Scipio and Venice, aged 48, died, July 25, of acute myocarditis

Edward Beach Loomis, Oak Park, Ill., University of Vermont College of Medicine, Burlington, 1870, aged 87, died, July 28, of coronary thrombosis and arteriosclerosis

Henry Hall Dodd, Millsboro, Del., Baltimore University School of Medicine, 1897, served during the World War, aged 65, died, June 27, of carcinoma of the mouth

Lester M. Brooks, Milwaukee, Milwaukee Medical College, 1912, member of the State Medical Society of Wisconsin, aged 46, died, July 23, of pulmonary tuberculosis

William Daus, Cleveland, Western Reserve University Medical Department, Cleveland, 1884, aged 74, died, July 11, of cerebral hemorrhage and arteriosclerosis

Frank Walton Larrabee, Boston, Dartmouth Medical School, Hanover, N. H., 1897, aged 65, died, August 8, of arteriosclerosis and cerebral hemorrhage

Samuel Douglas, Indian Head, Sask., Canada, Victoria University Medical Department, Coburg, Ont., 1890, aged 75, died, in May, of abdominal hemorrhage

Heaton Grant Daughters, Los Angeles, Kansas City (Mo.) Medical College, 1904, aged 68, died, July 16, of cerebral hemorrhage, nephritis and hypertension

I. Clark Gary ♂ Chicago, Chicago Medical College 1889, aged 77, superintendent of the People's Hospital, where he died, July 4, of coronary thrombosis

F. E. Shannon, Lebanon, Tenn. (licensed in Tennessee in 1889), member of the Tennessee Medical Association, aged 76, died, August 4, of uremia

Joseph W. Propeck, Oak Park, Ill., American Medical College, St. Louis, 1882, aged 76, died, July 15, of chronic myocarditis and nephritis

Edward Cline Lidikay ♂ Ladoga, Ind., Medical College of Indiana Indianapolis, 1903, aged 58, died, July 18, of carcinoma of the liver and rectum

James Abston McFerrin, Mountpleasant, Tenn., University of Nashville Medical Department, 1904, aged 55, died, July 21, of cerebral hemorrhage

Joseph Raoul Richardson, Indianola, Miss., Tulane University of Louisiana School of Medicine, New Orleans, 1924, aged 36, died, July 12

P. B. Hall, Rush Springs, Okla. (licensed in Oklahoma under the Act of 1908), aged 76, died, July 15, in Marlow, of cerebral hemorrhage

Nathaniel S. Macdonald, Sydney Mines, N. S., Canada, Dalhousie University Faculty of Medicine, Halifax, 1906, aged 58, died, May 22

Frederick Hill Stanbro, Springville, N. Y., University of Buffalo School of Medicine, 1887, aged 69, died, July 21, of cardiac infarction

John Lewis Corum, West Chester, Ohio, Hospital College of Medicine, Louisville, Ky., 1904, aged 60, died, July 19, of heart disease

James Joseph Morrow, Toronto, Ont., Canada, McGill University Faculty of Medicine, Montreal, Que., 1900, died, July 11

D. Victor Desrosiers, La Sarre, Que., Canada, Laval University Faculty of Medicine, Quebec, 1902, aged 60, died in June

John Curtis Pickett, Caledonia, Miss., University of Nashville (Tenn.) Medical Department, 1905, aged 56, died, in July

Rufus Choate, Washington, D. C., Georgetown University School of Medicine, Washington, 1867, aged 88, died, July 26

Leo Munter, San Francisco, Cooper Medical College, San Francisco, 1904, aged 60, died, July 1, of angina pectoris

William Amos Dilts, Indianola, Iowa, College of Physicians and Surgeons, Keokuk, 1887, aged 75, died, July 8

W. B. Leake, Jacksonville, Fla., Atlanta Medical College, 1879, also a druggist, aged 78, died, June 1

Philip W. Hawk, Zaleski, Ohio, Columbus Medical College, 1892, aged 72, died, July 5

Correspondence

"REVERSED COLLES FRACTURE"

To the Editor—In THE JOURNAL, June 29, page 2324, there appeared an article by Drs. Webb and Shemfeld entitled "Reversed Colles Fracture, with Special Reference to Therapy," in which it was stated that no cases of successful reduction of this type of fracture by the closed method had been reported. I feel that I must take exception to this statement, since Dr. J. B. Roberts (Notes on the Modern Treatment of Fractures, New York, D. Appleton & Co., 1899, p. 134) showed the roentgenogram and reported such a case successfully treated by closed manipulation by his colleague Dr. M. J. Stern. Since the reason for the difficulty of closed reduction of this type of fracture is unexplained by the authors, it is of interest to recall the case presented before the New York Surgical Society by Dr. J. M. Hitzrot (*Ann. Surg.* 61:740, 1915) in which attempted closed reduction was unsuccessful, operative intervention revealing that this was due to the piercing of the sharp distal end of the proximal fragment of the radius into the annular ligament. Reduction was easily performed after the proximal fragment was disengaged.

SIDNEY S. GAYNOR, M.D., New York.

[This letter was referred to George Webb of Brooklyn, who writes.]

To the Editor—The case of a reversed Colles fracture successfully treated by closed manipulation by Dr. M. J. Stern was in a young boy. A prereluction roentgenogram showing the deformity is given in Dr. Roberts' book. However, there is no postreduction roentgenogram and the success of the reduction is merely gaged by the fact that the lad had "little or no" deformity after the reduction. This is not convincing evidence of a successful reduction, since it is well known that in early youth most deformities following fractures have a tendency to correct themselves. The fact that successful reductions of this type of fracture are made only in isolated cases seems to emphasize our statement that in the majority of cases satisfactory anatomic replacement of the distal fragment can rarely be accomplished other than by open operation.

SYMPATHECTOMY FOR THROMBO-ANGIITIS OBLITERANS

To the Editor—In THE JOURNAL, June 29, was an editorial on "Sympathectomy for Thrombo-Angiitis Obliterans." This editorial is timely. About a year ago an editorial appeared in THE JOURNAL in which it was stated that sympathectomy had no place in the treatment of Buerger's disease. What I wish to call attention to, however, is the statement in the last paragraph: "It must be further emphasized that the operation (lumbar sympathectomy) is not only technically difficult even for the expert neurosurgeon but likewise a formidable procedure for the patient. The most serious complication is suppuration of the wound, which is particularly frequent in cases complicated by gangrene. The mortality even in the hands of the expert is not less than 4 per cent."

For years I have been advocating the use of the extra-peritoneal approach to the lumbar sympathetics. Appearing in the July issue of the *American Journal of Surgery* was a description of this approach through a muscle-splitting incision. Perusal of this article will elicit the fact that I have performed in the neighborhood of 150 lumbar ganglionectomies, approximately thirty of which have been for Buerger's disease, and that the operative mortality is nil.

The operation performed in this manner is neither a tremendous operation for the surgeon nor is it a formidable one for the patient. Complications have been virtually absent.

The original retroperitoneal exposure was described by Royle. I have modified his operation several times until at last I have a muscle-splitting extraperitoneal approach in which it is possible to get the patient up on the third day and out of the hospital in less than a week. In other words, when there is need of operating on both sides it is still possible to do the operations either at one sitting or three or four days apart and still have much less hospitalization than is necessary in the transabdominal approach, not to mention the tremendously lessened mortality.

P G FLOTHOW, MD, Seattle

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

CALCIUM IN CHILD'S DIET

To the Editor—It is my understanding that a quart of cow's milk contains approximately a gram of calcium and that this is considered the desirable amount for a growing child. Kindly answer or discuss the following questions: 1. How much calcium does a liter of human milk contain? 2. At different ages or different periods of growth do children require different amounts of calcium? Specify. 3. Is the ratio between calcium and phosphorus the same in cow's milk as in human milk? In the following questions it is understood that the hypothetical child is receiving an adequate supply of all the known vitamins and especially vitamin D. 4. If a healthy normally growing child between the ages of 2 and 14 years drinks a pint of milk each day and eats a good general diet containing liberal amounts of green vegetables and fresh fruits is additional calcium indicated? 5. In the case of a healthy normally growing child who drinks only a few ounces of milk each day or even none at all but who eats well of a normal and well balanced diet, should additional calcium be prescribed? 6. When additional calcium is necessary or desirable should it be administered in a form in which the calcium-phosphorus ratio is the same as in human milk? Name one or more such preparations and their relative merits. Is the calcium of some preparations more readily ionizable than that of others? 7. Discuss the merits or demerits of dicalcium phosphate, tricalcium phosphate, calcium lactate, calcium gluconate and calcium carbonate. 8. Is there any advantage in incorporating a calcium salt with cod liver oil? If so which calcium salt should be preferred? In discussing the various calcium salts please state the comparative costs of the various preparations bearing in mind that a child with subnormal calcium intake in his diet might require medicinal calcium over a period of years. Please omit name.

MD Ohio

ANSWER.—1 A liter of human milk contains about 1.24 Gm. of calcium.

2. The only way that this question can be answered is by a study of calcium and phosphorus metabolism experiments. Sherman has summarized the data from the literature and his table is here given.

Average Calcium and Phosphorus Storage of Children in Grams per Kilogram Daily (Sherman and Hawley)

Age	Calcium				Phosphorus			
	No of Cases	In take	Out put	Bal. ance	No of Cases	In take	Out put	Bal. ance
1-6 months	32	0.090	0.063	+0.027	11	0.075	0.058	+0.017
7-12 months	14	0.137	0.098	+0.039	5	0.115	0.087	+0.028
1-2 years	5	0.089	0.070	+0.019				
3-8 years	13	0.039	0.028	+0.011	10	0.054	0.046	+0.008
9-14 years	14	0.027	0.018	+0.009	11	0.039	0.029	+0.010

From a perusal of this table it is evident that the ratio of retained calcium to retained phosphorus alters with age. In the young child calcium is retained in excess while in older children phosphorus is retained in excess. From such a table it can be further stated that it is difficult to define calcium requirement without defining phosphorus requirement. A third variable is the exact amount of vitamin D in the diet.

3. The ratio of calcium to phosphorus in breast milk is about 2, 2, in cow's milk, 1, 3.

4. No if his calcium metabolism is positive.
5. No if his calcium metabolism is positive. It might be added however, that absorption of calcium from milk is said to be greater than from other sources.

6. It has already been shown that as the child grows older the ratio of absorption varies and that therefore it would seem fair to say that the optimal calcium-phosphorus ratio would vary with age. The calcium of some preparations is more readily utilized than that of others.

7. From what has been said, the questioner should be able to draw his own conclusions as to the merits of the preparations mentioned. The various preparations are discussed in New and Nonofficial Remedies.

8. There is no advantage in incorporating a calcium salt with cod liver oil.

TREATMENT OF TUBERCULOSIS

To the Editor—Dr. A states that he has treated over a thousand cases of pulmonary tuberculosis by means of rest in bed, general hygienic measures, ultraviolet rays to the chest twice a week, and injections of tuberculin subcutaneously twice a week. He reports uniformly good results and states that this treatment is rendered in all cases irrespective of fever of 103 and 104 F. Dr. B holds that this treatment is not rational as both tuberculin and ultraviolet rays are contraindicated in cases showing any marked elevation in temperature. Will you please give me the latest medical opinions regarding the use of tuberculin particularly in the treatment of pulmonary tuberculosis? Please omit name.

MD Illinois

ANSWER.—Dr. A does not state just what he means by uniformly good results, that is, whether all patients showed some evidence of improvement or all were restored to good working capacities. If nothing more was done for his patients than rest in bed, general hygienic measures, ultraviolet rays to the chest twice a week and injections of tuberculin subcutaneously twice a week, his treatment is approximately that of two decades ago and does not offer to his patients the advantages of the more valuable methods of treatment, such as collapse therapy. Moreover, Dr. A does not state the type of pulmonary tuberculosis or its extent. If he has treated more than 1,000 cases of frank pulmonary tuberculosis of the true clinical type and has restored all his patients to good working capacities, he probably holds the world's record for the treatment of tuberculosis. Moreover, if he has carefully selected 1,000 cases, many of only childhood tuberculosis or nonprogressive disease, it is still difficult to understand how every one of the entire 1,000 patients will continue on full working capacity long. Doubtless, Dr. B's criticism is on the ground that many of these patients should have had the advantage of other standard and more effective methods of treatment and that tuberculin and ultraviolet rays should be administered only in carefully selected cases.

While the pendulum swung far in favor of heliotherapy a few years ago, it has now settled back to approximately its proper place. It is not looked on as a panacea in the treatment of tuberculosis, it is only an adjunct and even in this capacity is administered only in carefully selected cases.

After Koch recommended tuberculin as a therapeutic measure, the pendulum swung far in its favor. Later when the good results anticipated were not forthcoming, the pendulum swung equally far in the opposite direction. At present there is a small group of physicians in this country who use tuberculin in the treatment of pulmonary tuberculosis. Nearly every one looks on it as a preparation to be avoided when any significant elevation of temperature is present. However, it is still considered helpful by a few workers in cases presenting but few or no symptoms, in which pulmonary lesions apparently have reached a standstill, that is, cases which are not definitely progressive or well under control. It is thought that in such cases tuberculin may result in a slight reaction around the lesion which simulates the hyperemia seen around a positive intracutaneous tuberculin reaction and that this may suffice to stimulate fibrosis. Most physicians believe that in any progressive pulmonary lesion tuberculin is not indicated.

The question arises as to whether the good results reported by some physicians following the administration of tuberculin as a therapeutic measure in carefully selected cases are not due to a partial and temporary desensitization. The fact is apparently well established that allergy to tuberculin is responsible for the intense reaction about a focus of tubercle bacilli, which so frequently results in necrosis and cavitation. It is possible that tuberculin will be used much more extensively than at present, not to treat persons seriously ill with tuberculosis but to desensitize those who are highly allergic, in order to prevent intense reactions in case reinfection does occur. Partial desensitization has been found possible but, unfortunately, is only temporary. To insure against destruction, the tissues should be kept desensitized over a period of many years, that is, during those periods when tuberculosis approaches, reaches and descends from its mortality height. Obviously, this would be difficult to accomplish for many persons because of the long time necessary, as well as the expense. Tuberculin may still have an important part to play in tuberculosis, but at the present time this does not seem to be in the field of clinical, progressive disease with or without elevation of temperature.

AIR CONDITIONING NURSERIES

To the Editor—Our hospital has recently been air conditioned and the question arose as to whether or not the babies should be taken out of the nursery to their mothers in the cool rooms. We have been raising the windows and wrapping the babies in light blankets and so far have had no trouble. Do you know of any instances in which a baby has contracted a cold under these circumstances?

EDWIN C. McMULLEN MD Pine Bluff Ark.

To the Editor—I shall greatly appreciate a letter from you stating your opinion of the advantages of air conditioned infant nurseries over nurseries that are not air conditioned for both summer and winter months. We are located fairly well south but have extreme temperatures around 106 F in summer and some subzero in winter.

K C REESE MD Tulsa Okla

ANSWER.—Only a few hospitals have been air conditioned, consequently data are not available on which to base a reply. But if a common sense view of the situation is taken, it would not seem a hazard to take a normal nursing infant from the nursery to an air cooled room. The moment the baby leaves the nursery and is taken into the hall, he experiences at once a change of temperature. In the cooler season of the year, particularly in the winter, the baby is taken outdoors, where he is subjected to a decided change in temperature, which may amount to from 35 to 50 degrees F or more. Ordinarily the babies suffer no unfavorable consequences from being taken outdoors in the winter, particularly if they are properly clad and extreme chilling and high winds are avoided.

The answer to the question would seem to be that a baby may be carried into an air cooled hospital room if he is sufficiently protected by proper clothing or a blanket.

There can be little doubt that high temperatures of summer, reaching an extreme of 106 and heated hospitals in subzero weather are not conducive to the best of health, for either infants or adults. When the cold air of winter is heated in a building, it expands and becomes dry unless some device is provided to humidify it. It often requires a temperature of 80 F or more for heated dry air to be comfortable. During and following heat waves of summer, even with a maximum temperature of no more than 100, a good many deaths are reported among elderly and somewhat debilitated persons as being directly due to the heat. Doubtless, many others die from conditions that might be indirectly accounted for by high temperature. It would seem more than likely that there is considerable loss of life in infancy, either directly or indirectly, from the high atmospheric temperature.

The Chicago Ventilation Commission (Report of Chicago Commission on Ventilation, 1914) and the New York Ventilation Commission (Ventilation Report of the New York State Commission on Ventilation, New York, E. P. Dutton & Co., 1923) found that three physical qualities, namely, temperature, humidity and circulation of air, are important not only for comfort but also for the health of human beings. The temperature found best was approximately 68-70 F, with a relative humidity of from 40 to 50 per cent, with the air slowly circulating.

Blackfan and Yaglou (*Am J Dis Child* 46 1175 [Nov, part 2] 1933) made a careful study of atmospheric conditions on the growth and development of premature infants, using as controls normal, full-term infants. These workers had available unconditioned as well as conditioned nurseries, so that they could make comparisons of results in the two types. They found that in premature infants the heat-regulatory mechanism was not adequate to protect them against either too high or too low temperatures. A humidity of 65 per cent, with a temperature ranging from 75 to 100 F, was found best. Of course each premature infant had to be treated individually because of differences in body weight, fetal age, and so on. A humidity as low as 30 per cent often led to serious consequences. The net mortality for all weight and age groups was 28.9 per cent in the unconditioned nursery as compared with 7 per cent in the conditioned nursery. Infections both acute and chronic accounted for 70.3 per cent of the total number of deaths in the unconditioned nursery and 31.9 per cent in the conditioned nursery. They state that in the light of their study the importance of optimal temperature, humidity and ventilation conditions in the growth and development of premature infants is demonstrable.

Obviously the special air conditioning employed by Dr. Dafoe may have been helpful in saving the lives of the quintuplets. As the heat-regulatory mechanism is adequate to protect normal, full-term infants, they do not require the high degree of temperature or the high relative humidity that premature infants need. Therefore, in nurseries for such children ordinary air conditioning suffices. There is no question about the advantage of conditioning the air so that the temperature is held

constantly at that degree which has been found best for the body and with a relative humidity in which the body thrives best with a slow circulation of air and all dust and other contamination filtered from it.

SLIGHT FEVER DURING PREGNANCY

To the Editor—A woman aged 26 is pregnant the second time. With both pregnancies her temperature has been as high as 99.6 F. Apparently the elevation of temperature begins about six weeks after the onset of pregnancy. With the first pregnancy the fever stopped at about the sixth month. She is now in the third month of the second pregnancy and has a fever. At the first delivery, which was a very difficult one, I noted that the patient was almost without amniotic fluid. I was wondering whether the fever absorbed this fluid. The patient is a nurse and went through training without missing a single day. Her weight before marriage was 120 pounds (54 kg). It increased with the first pregnancy to 150 pounds (68 kg). From the genito-urinary standpoint she is normal. Nothing can be found to account for any elevation of temperature. The ears, nose, eyes and throat are normal, with the exception of the small deflected septum. The specialist says that this is not causing the fever. The tonsils have been removed. The teeth are in good condition. The patient began menstruation at the age of 14 years. Menstruation lasted for seven days up until the age of 18 years, when dysmenorrhea developed after which the duration gradually declined to about four or five days. She was married at the age of 24 after which menstruation was cut down to about three days which continued as such until three months before pregnancy and then became a day and a half. While in training the hemoglobin was from 80 to 85. At present it is between 70 and 80. With this temperature she does not have any night sweats. The physical examination of the chest apparently gives normal results. I have never roentgenographed the chest. When the patient is not pregnant she has a normal temperature. The urine has always been normal. The blood pressure is around 100 being a little low. The action of the bowels is satisfactory with an occasional dose of magnesia magma. She is said to have had an attack of appendicitis at the age of 15 but has had no further trouble. There have been no abdominal operations. She was told that she had a cardiac leakage but I cannot make out anything wrong with the heart. During her pregnancies I have kept her on a well balanced diet with a quart of milk a day. The patient presents a rather normal history all the way through but I am wondering if she has a mild toxemia of pregnancy which is manifesting itself through this slight elevation of temperature. She has an occasional headache. A Wassermann test was not made. I do not believe that chronic malaria would manifest itself as such in this way. The patient was born in the malarial belt. There is no tuberculous history in the family as far as she can recall. Please omit name.

MD Florida

ANSWER.—A slight degree of fever during pregnancy may be found in not a few cases in prenatal clinics and it is rare that any pathologic change is discoverable to account for it. Older writers mentioned a "fever of pregnancy," but modern investigations have shown that tuberculosis, pyelitis, appendicitis, allergy and other causes were operative. If the patient is well there is no reason for any concern on the part of the physician.

SYPHILITIC MENINGO ARTERITIS

To the Editor—A man aged 30 had a sore on the penis five years ago. Six weeks ago he had a sudden attack of severe headache and partial paralysis of the left arm. Today he is weak, very nervous, has a shaking of the left leg controlled by placing his foot on the floor and he can move the left arm fairly well. He had a positive Wassermann reaction and spinal puncture controlled the headache. Is it possible for syphilis to cause such an attack of the brain and cord system five years after the primary lesion? Would regular antisyphilitic treatment suffice? Please omit my name if printed.

MD Minnesota

ANSWER.—The patient is undoubtedly suffering from a syphilitic meningo arteritis, probably of a localized type and with sufficient extension to have caused pressure on important nerve paths following a localized hemorrhage. It of course is difficult to place this focus, but it probably is above the decussation on the right side.

It is unfortunate that the correspondent did not mention the condition of the spinal fluid. Undoubtedly the patient has a high cell count, a positive globulin increase in the central zone of the colloidal gold curve, and a positive Wassermann reaction on the spinal fluid. He should be put on antisyphilitic treatment at once. Potassium iodide in 0.5 Gm doses should be given after meals and for two weeks the intramuscular injection of the aqueous solution of sodium bismuth tartrate, 0.2 Gm., or of iodobismuto 2 cc., or of sodium bismuth thioglycollate, 0.2 Gm., every other day. The patient might then be started cautiously on neosarsphenamine injections intravenously, the first dose being 0.3 Gm., followed in five days with a dose of 0.6 Gm. and if the patient stands this all right, an injection of 0.75 Gm. every week until he has received a total of twelve injections of the arsenical. Following the last injection of the arsenical, the patient may be given an injection of one of the bismuth suspension preparations for example, bismuth salicylate or potassium bismuth tartrate, these injections

being given once a week for a series of ten injections, to be followed with twelve further injections each of 0.75 Gm of neoparsphenamine, this in turn to be followed by a further course of bismuth injections. If the patient stands this therapy well he should have three or four courses of the arsenical and of the bismuth preparation. A Wassermann test should be taken at the end of each course of treatment and a lumbar puncture every six months to observe progress. Certain cases of this type respond nicely to antisyphilitic therapy, though it is well to get the therapy started before the hemorrhage has had an opportunity to become too firmly organized, and in an important condition of this type, if there is any question as to the method of handling the patient, one should have the patient consult a well trained syphilologist. It may mean the difference between a permanent disability and complete recovery.

DOSAGE OF ROENTGEN RAYS

To the Editor—Please give me the number of roentgens required to give an erythema dose on a skin area of 10 by 10 cm with the following settings

100 kv	5 ma	no filter
100 kv	5 ma	1 mm of aluminum
125 kv	5 ma	no filter
125 kv	5 ma	1 mm of aluminum
125 kv	5 ma	3 mm of aluminum
160 kv	5 ma	0.25 mm of copper plus 1 mm of aluminum
175 kv	5 ma	0.25 mm of copper plus 1 mm of aluminum
200 kv	5 ma	1 mm of copper plus 1 mm of aluminum
200 kv	5 ma	0.5 mm of copper plus 1 mm of aluminum
200 kv	5 ma	0.75 mm of copper plus 1 mm of aluminum

At 100 kilovolts without filtration the skin will generally tolerate 350 roentgens with a hardly noticeable erythema on the tenth day. Recently I have seen recommended 900 roentgens as an erythema dose when 200 kilovolts is used filtered through 1 mm of copper plus 1 mm of aluminum. This seems to me to be too much. I shall appreciate a statement from you as to what is considered an average erythema dose with the foregoing factors.

G E HELSCHEN M D Sherman Texas

ANSWER.—Under exactly similar physical conditions the output of different generators of x-rays, measured in international roentgens, should be the same. In ordinary practice, however, exactitude of physical conditions seldom obtains. Moreover, erythema represents a biologic reaction of the skin and the tolerance of different skins varies considerably. For these reasons the dose in roentgens required to induce erythema depends on the generating apparatus and tubes, the conditions under which these are operated, the conditions of measurement, the tolerance of the subject's skin, and the degree of erythema taken to represent the erythema dose. Measurement of the x-ray output of different installations may vary within fairly wide limits. Also, measurement with an ionization chamber in air or with the chamber in contact with the skin gives widely different results. In the latter case the scattered radiation is included, whereas in the former it is excluded.

In all probability the erythema dose of 900 roentgens mentioned by the enquirer represented a dose measured with the ionization chamber in contact with the skin which would roughly be about 40 per cent greater than the number of roentgens registered by the ionization chamber if the measurement had been made with the chamber free in air. Measured in air, the average erythema dose with a peak voltage of 140 and with filtration of 6 mm of aluminum, should be from 550 to 600 roentgens. With higher voltages and greater filtration a somewhat larger dose may safely be given.

MALIGNANT GROWTHS OF ANTRUM

To the Editor—How frequently do malignant growths of the maxillary antrums occur as determined clinically and radiographically? References on epiphyseal development in standard anatomy textbooks do not coincide in all age periods as checked by roentgen examination. Have any comprehensive roentgen studies been made recently? Please omit name.

M D New York

ANSWER.—Malignant growths of the antrum are relatively infrequent. The number of this type of new growth as compared with the total number of patients frequenting several of the world's largest nose and throat clinics gives figures varying from 0.03 to 0.12 per cent.

Another source states that malignant neoplasms of the nose and its accessory cavities represent about 1 per cent of all malignant growths and about 1 in 800 of all cases of nasal disease.

A search of the literature does not reveal any roentgen studies of the maxillary sinus devoted solely to the discovery by this method of the incidence of carcinoma in this region.

Perhaps one answer to the question would be the statement of one authority (Oehngren), who feels that "a more widespread

use of x-rays for diagnosis in the case of pains in the trigeminal nerve area and a more general use of them in unilateral subacute rhinitis in those over the age of 50 would result in a smaller number of overlooked tumors of the antrum. Too many of them in the past have been going about for months with a diagnosis of neuralgia or toothache."

There is no exact agreement on the question of epiphyseal development because of normal variations. In general, the anatomists agree and their observations coincide more or less with those of the roentgenologists (Cohn Isadore Normal Bones and Joints, New York, Paul B Hoeber, Inc., 1924).

CONJUNCTIVAL IDIOSYNCRASY TOWARD ARSENIC AND BISMUTH

To the Editor—I am treating a messenger boy weighing about 121 pounds (55 kg) for syphilis. I began by giving him 0.45 Gm of neoparsphenamine every five days for six injections and then every seven days for another six injections. I followed with 0.2 Gm of sodium hyaluronate intramuscularly every seven days for twelve doses. Then I omitted treatment for three weeks and drew blood for a Wassermann test which was negative. I then began again on the same routine as before. The boy rode a bicycle every day except Sundays all through the winter. He is in excellent physical and mental condition and cooperates intelligently in every way. On the day after the first neoparsphenamine injection a slight conjunctivitis developed in both eyes with a marked increase in the flow of tears. The conjunctivitis subsided when the eyes were protected by goggles when he was in the open air but the flow of tears is so intense that often he will have patches of moisture covering nearly the entire front of his coat. There seemed to be no difference when he was treated with arsenic and bismuth compounds. After his three weeks rest period he was almost back to normal when on the day after the first injection of the second course the process appeared as violent as before or perhaps more so. I have never had this complication confront me before although I have treated many such patients in much the same way. What I wish to know is whether or not there is any possibility of real danger to the eyes and how to treat the condition so that he can keep at his job in the open air. Please omit name and address.

M D Illinois

ANSWER.—Without specific knowledge as to the appearance of the conjunctiva and cornea, it is rather difficult to answer the question. Apparently there does not seem to be any interstitial keratitis present but merely an epiphora consequent to the administration of arsenic or bismuth compounds. As there are remissions of the lacrimation in the rest periods, it is evident that dacryocystitis is not present. Consequently, this must be one of those extremely rare cases of a conjunctival idiosyncrasy toward arsenicals or bismuth. Reference to this can be found in the *Kurzes Handbuch der Ophthalmologie*, volume 7, Syphilis and the Eye, by Igersheimer, page 173 wherein cases reported by Simon Naegeli, Kleeberg and Kraus are cited. The only relief that can be obtained is to treat the syphilitic condition with mercury and iodides instead of arsenic or bismuth compounds.

DISCOLORATION OF HAIR AFTER PERMANENT WAVE

To the Editor—An unmarried woman aged 43 complains of a yellowish color beginning at the scalp line extending out on the shafts of the hair following permanent waves. She has been bothered with this condition for six years ever since receiving her first wave. The hair is healthy it is prematurely grayed and there are no scalp disturbances. Six years ago a total thyroidectomy was performed two years ago a suprapubic hysterectomy and some years ago a tonsillectomy. Physical examination and a complete laboratory check up are all negative. She further states that four years ago she reported to some physician who administered heavy doses of alkali which seemed to give relief for a while. The only other significant fact in the history is constipation which is not very marked. Examinations of the urine and the blood are all negative. The Wassermann reaction is negative. Can you give me some idea as to why this peculiar yellow pigment seems to be depositing in the hair shafts? I will appreciate any suggestions as to treatment.

M D New York

ANSWER.—Yellow hair is not uncommon in cases of icterus and has occurred after the use of resorcin lotions. No report of yellow hair after the permanent wave procedure has been found, but Philipsen (*Green Discoloration of the Hair After Permanent Waving*, *Ugeskr f Lager* 95 746 [June 29] 1933) reports green hair in seven of his patients after the permanent wave. All had previously used lotions containing mercury solutions. He remarks that it is no wonder that a mercurial solution in combination with an alkali under great heat should undergo a chemical reaction. So far as his experiments had been carried, he had found no other chemical that reacted under these conditions. The sulphur in the hair is, he thinks, in too firm a combination to cause any change of color.

In the case described the color is confined to the portion of the hair shaft next the scalp. This would suggest that the color was due to something on the scalp. Is the patient taking

iodine or bromine? The ammonia salts of these halogens turn yellow on exposure to the air. Has resorcin or naphthol been used on the scalp?

Unless some such cause can be found and removed, treatment must be limited to the substitution of milder methods of hair curling for the popular permanent wave.

ANTIMENINGOCOCCUS SERUM

To the Editor—I should like to know whether there is any value in a prophylactic injection of antimeningococcus serum given hypodermically on the day of exposure. Is any immunity conferred by such use of a serum supposedly adapted for intraspinal injection? Would intramuscular injection cause less reaction (anaphylactic) or more than hypodermic? Three years ago one brand was given hypodermically to two patients without any other ill effects than a sore arm temporarily. Recently, of three patients who received a different brand two suffered a severe urticaria a week after the injection while the other patient suffered a pyrexia of 101 F beginning two days after the injection and lasting ten days the latter's arm was very red and inflamed while the arms of the patients with urticaria suffered little pain at the site of injection. If the serum has a prophylactic value what amount should be given? Please omit name.

M D, California

ANSWER—There is ground for belief that antimeningococcus serum has prophylactic virtues. Ordinarily the preventive effect would last only three or four weeks. Practically the same preventive effect, or passive immunity, would result from intramuscular as from intraspinal injection. The danger of serum reaction would be about the same, no matter what the route of injection. Serum reactions depend on the sensitivity of the patient, the brand of serum and the age of the serum. Different brands of serum vary in their content of reaction-producing substance, and older serums are regarded as less dangerous than recent. No effective dose has been established for preventive purposes, it would seem reasonable to give at least a full therapeutic dose. The fact that such preventive injection may sensitize the subject to horse serum should be borne in mind.

UNDULANT FEVER AND PREGNANCY

To the Editor—I have a patient four and a half months pregnant, who has undulant fever. From her history I judge that she apparently has had the infection about twelve months. Should the infection fail to subside before her delivery is it most likely that the new born infant will be similarly infected? If so what line of treatment is recommended? At present the patient is being treated with Brucella melitensis vaccine (Lederle) tonics and general hygienic care. Any information relative to the handling of this case would be appreciated. The patient's general physical condition is not bad. She was not aware that she had any fever at any time until demonstrated by a thermometer. There is a small dental root abscess as shown by the x-rays. She has a slight anemia (erythrocytes 3,700,000 hemoglobin 65 per cent). The urine Wassermann and Kahn reactions blood urea and basal metabolic rate are all normal. The temperature fluctuates between 97 and 100 F and the pulse between 78 and 94 at complete rest in bed and 88 and 120 when up and about. The agglutination test is positive for undulant fever.

M D, Arkansas

ANSWER—It is quite unlikely that the child will exhibit evidence of undulant fever. This statement is based on the fact that calves born of cows with brucellosis rarely, if ever, show evidence of the disease.

AMINOACETIC ACID IN MYASTHENIA

To the Editor—I saw a case of pseudohypertrophic muscular dystrophy or myopathy in a child aged 7 years. Is there anything new in the treatment for such cases? Would the induction of artificial hyperpyrexia be of any benefit in a case of this kind? Is there any hospital or clinic to which I could send this child for further study?

J L. SNAVELY M D Sterling III

ANSWER—The administration of aminoacetic acid has been advocated in the treatment of myasthenia and myopathy, though the value and limits of its usefulness have not been determined. Many neurologists and most neurologic departments of university medical schools are interested in this problem.

GANGRENE OF UTERUS

To the Editor—At autopsy a uterus is found black and gangrenous. How long would this condition take to develop? (The case in question is a possible criminal abortion at approximately three months and I can find nothing in my reference books regarding it.) Kindly omit name.

M D California

ANSWER—It is not possible to answer this question satisfactorily without further information. All that can be said is that discoloration and gangrenous changes may develop in the course of a day or so after abortion.

Medical Examinations and Licensure

COMING EXAMINATIONS

- AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY Written examination and review of case histories of Group B applicants will be held in various cities of the United States and Canada Dec 7. Applications must be filed not later than Nov 1. Sec. Dr. Paul Titus 1015 Highland Bldg., Pittsburgh (6).
- AMERICAN BOARD OF OPHTHALMOLOGY St. Louis Nov 18 Sec., Dr. William H. Wilder 122 S. Michigan Ave. Chicago.
- AMERICAN BOARD OF ORTHOPAEDIC SURGERY St. Louis Jan. Sec. Dr. Fremont A. Chandler 180 N. Michigan Ave. Chicago.
- AMERICAN BOARD OF PROCTOLOGY Philadelphia Oct 10 and St. Louis Nov 20 Sec. Dr. C. A. Aldrich 723 Elm St. Winnetka Ill.
- AMERICAN BOARD OF RADIOLOGY Detroit Dec 12 Sec. Dr. Byrl R. Kirklind Mayo Clinic Rochester Minn.
- ARIZONA Phoenix Oct 12 Sec. Dr. J. H. Patterson 876 Security Bldg. Phoenix.
- ARKANSAS Basic Science Little Rock Nov 4 Sec. Mr. Louis E. Gehauer 701 Main St. Little Rock.
- CALIFORNIA Sacramento Oct 21-24 Sec. Dr. Charles B. Pinkham, 420 State Office Bldg. Sacramento.
- COLORADO Denver Oct 1 Sec. Dr. Harvey W. Snyder 422 State Office Bldg. Denver.
- CONNECTICUT Basic Science New Haven Oct 12. Prerequisite to license examination. Address: State Board of Healing Arts 1895 Yale Station New Haven.
- GEORGIA Atlanta Oct 8-9 Joint Secretary State Examining Boards Mr. R. C. Coleman 111 State Capitol Atlanta.
- IDAHO Boise Oct 1 Commissioner of Law Enforcement Hon. Emmett P. Post 205 State House Boise.
- ILLINOIS Chicago Oct 22-24 Act. Supt. of Regis., Dept. of Regis. and Edu. Mr. Clinton P. Bliss Springfield.
- MICHIGAN Lansing Oct 8 Sec. Board of Registration in Medicine, Dr. J. Earl McIntyre 202-3-4 Hollister Bldg. Lansing.

- WYOMING Cheyenne Oct 7 Sec. Dr. G. M. Anderson Capitol Bldg. Cheyenne.

Minnesota June Examination

Dr. Julian F. Du Bois, secretary, Minnesota State Board of Medical Examiners, reports the oral, written and practical examination held in Minneapolis, June 18-20, 1935. The examination covered 12 subjects and included 60 written questions. An average of 75 per cent was required to pass. Forty candidates were examined, all of whom passed. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
University of Colorado School of Medicine	(1933)	90.1	
Yale University School of Medicine	(1932)	85.4	
Loyola University School of Medicine	(1934)	91.3	
Rush Medical College	(1934) 91.2	(1935)	84.1

Book Notices

Backache. By James Mennell M A M D B C Medical Officer
Physio-Therapeutic Department St Thomas's Hospital Second edition
Cloth. Price \$3.50 Pp 227 with 59 illustrations. Philadelphia P
Blakiston's Son & Co Inc 1935

In this edition the author has added more than thirty pages and eleven illustrations. The book is ingeniously illustrated in red and blue, the former showing the patient and the latter the examiner or manipulator, presenting instructive outlines. The differential diagnosis and treatment of the various causes of backache have advanced remarkably. The book represents the work of eleven years, including his study during two visits to the United States. The author states that he has presented nothing that lies outside his personal experience. He deals with the simplest technic. He has been conservative and described only the more simple of the manipulations that can be put to daily use. He calls attention to the inadequacy of the routine examination of the back as generally practiced and the injustice of the opinion formed in the early period of his study of backache that all the patients grossly exaggerated the symptoms and that the symptoms themselves were to a considerable degree neurasthenic, often almost amounting to delusion. The author believes that it is only as a result of an adequate routine examination that one can arrive at a definite diagnosis. He has elaborated a complete method of examination. He believes that most of the pitfalls in the diagnosis of backache can be overcome or evaded by careful history taking. The book is to be highly recommended.

Entstehung und Funktion von Gefäßsystem und Blut auf cellular physiologischer Grundlage. Von Dr med Max Hausmann Paper Price 56 Swiss francs 44.80 marks Pp 704 with 207 illustrations. Basel Verlag Benno Schwabe & Co 1935

This volume is of especial interest to the student of zoology, anatomy and physiology. The author is a Swiss physician who in thirteen years of assiduous labor has found the time and energy for this extensive work. On the whole, the book represents an attempt to combine the views, theories and results of specialized research in the fields of zoology, embryology, physiology, hematology, pathology and clinical medicine. The author justly points out that intensive specialization has led too often to incomplete solutions of general biologic problems. The volume is essentially theoretical and contains no experimentally gained contributions by the author.

The vast literature pertaining to this field is critically reviewed. Throughout the book it is evident, however, that American literature has hardly been consulted by the author, a tendency that is all too common with European writers.

To the clinician the book will be of interest particularly in its chapters dealing with the reticulo-endothelial system, the origin of red blood corpuscles and of leukocytes, the hematopoietic organs, the physiology of capillaries and the physiology of the circulatory system as a whole.

The theoretical views of the author are expressed in the introductory chapter and are summarized in the final chapter. The body of the book represents mainly documentation for his deductively gained opinions and consists of three parts, each containing reviews of pertinent phylogenetic and ontogenic studies and theories of the circulatory system (part I, invertebrates,

pp 10-216, part II, vertebrates [early stages] pp 217-400, part III, vertebrates [later stages] and physiologic synthesis, pp 401-634).

The author's discussion of the morphogenesis of the vascular system is based on Arnold Lang's theory of the trophocoel. A summary of this theory and detailed discussion is given in chapters 2 and 3. Hausmann accepts Lang's views as a profitable and stimulating hypothesis although he recognized certain objections and finds it necessary to apply it less vigorously than its founder. Indeed, the author emphasizes that it is impossible to explain the origin of the vascular system by a general morphologic theory applicable to all classes of the animal kingdom.

The question of the origin of endothelium is recognized as a particularly difficult problem. With respect to endothelium in vertebrates, the author refers to the views of Fernandez and Näf former pupils of Lang, who accept its mesenchymal origins. Hausmann is disinclined to believe, however, that this is true for all metazoa. Important American contributions to this problem by Evans, Hockard and Reagan are not discussed. The work of Evans is merely referred to, indirectly from Ketbel and Mall's handbook. With regard to the local origin of endothelium, the author's discussion is centered on Hatta's work.

That the author is strongly influenced by Lang's theory, in spite of its admitted limitations, is evident by the fact that he sees no difficulty in considering the vascular endothelium of vertebrates as derived from separated coelomic elements. The endothelial linings would thus represent a secondary coelomic cavity. Similarly, Hausmann considers the blood islands of the yolk sac as emigrated coelomic elements which secondarily produce the capillary network. The theory of His of the parablaster is considered antiquated and has been abandoned.

In the introductory chapter the author states that a true lymphatic system with endothelial linings of its channels appears for the first time in birds. This statement reveals that the author has not looked deeply and widely into the literature pertaining to that system, for the unquestioned existence of such a system in the vertebrates below the birds—in fishes, amphibia and reptiles—has been accepted for a century. He accepts without discussion the direct origin of lymphatics by outgrowth from veins, a statement which shows again that he has not taken the trouble to acquire thorough information about established investigations in this matter (Huntington, McClure, Kampmeier).

The book contains no independent chapter on the lymphatic system, there are, however, subtitles dealing with lymphoid organs and lymphatics in chapters 23, 26 and 27. Although the author points out, in these summary discussions, the preeminence of American anatomists in this field, the only author indirectly quoted is Sabin, whose views he accepted without question. Hausmann passes over in silence the evidence contained in a great number of researches on the origin and development of the lymphatic system which refute the views of Sabin.

The author's main thesis centers in the consideration of the function of an organ or organ system not as a narrowly circumscribed partial function of the organism as a whole. Hausmann perceives an organ and, indeed, the entire organism as the result of a synthesis of cells which carry all primary functional characteristics and which gain their specific function only through influences of their particular environment. His views represent a closer correlation of phylogenetic and ontogenic origin with principles of general physiology of the cell. The analysis of the vascular system from this point of view was undertaken as an example and test for the validity of such an approach.

It may be questioned, however, whether the author has been successful in escaping the dangers that are innate in any such attempt to fit biologic facts and theories with deductively preconceived opinions. Modern biology is not being written in a study or in libraries. The author exhibits a tendency toward verbosity that does not add to the clearness of his argument.

The book is excellently printed. The illustrations are borrowed from original papers and credit is given to the respective sources. Fifteen diagrams are the author's own. A valuable feature of the large volume consists in marginal titles on every page. There is an excellent subject and author's index. The subject index gives helpful definitions for many zoological, anatomical and physiologic terms.

The Doctor's Bill By Hugh Cabot With an Introduction by A. Lawrence Lowell Cloth Price \$3 Pp 313 New York Columbia University Press 1935

The first three chapters survey general medical developments and resources in this country. They contain a description of the complexity in medical practice due to the development of hospitals and specialization. A chapter on the general practice of medicine conveys the idea that the general practitioner is being crowded out of the field a conclusion that is emphasized in the next chapter, on specialists and group medicine. In this the author argues the superiority economically and medically of group practice. This argument is continued in the succeeding chapters, in which he accepts without question the conclusions of the Committee on the Costs of Medical Care as to lower costs of group practice and endorses the practice of contract medicine by groups.

The author recognizes the abuses that have grown up under workmen's compensation but does not seem to recognize that these abuses are closely connected with some of the forms of contract practice associated with compensation administration.

There is a review of health insurance in continental Europe and the British Isles, in which these systems are presented from a much more favorable point of view than a wider knowledge of those systems would seem to justify. Nevertheless, the author concludes "I cannot convince myself that the conditions in this country can be satisfactorily met by transplanting plans which are at least apparently, satisfactory in other countries." He also says "Some study of the problems in Europe leads me to the opinion that a grade of medical service which is apparently entirely satisfactory, and probably fairly meets the demand in various of those countries, would fall short of the demand here and would prove unsatisfactory." He is under the impression that "the subdivision of the field of medicine and the development of specialization have on the whole gone considerably further in this country than abroad." Thus conclusion is not in accord with facts.

The author's discussion of medical needs in the United States again follows the conclusions of the Committee on the Costs of Medical Care and among "suggested methods of improvement" are various systems of voluntary insurance, especially medical insurance by private groups of physicians. In regard to the recent movement of county medical societies to organize medical service he says "If the medical profession can succeed in delivering a satisfactory article of medical service through the united efforts of organizations such as the county medical societies, it will have gone far to justify its claim of being capable to handle such problems on its own initiative." He enters into some controversial questions within the American Medical Association and accepts the purported statements of some of the critics of the American Medical Association but shows that he is thoroughly unfamiliar with many of the facts.

In his final chapter, "Where Do We Go from Here?" he criticizes the demand of the medical profession for free choice of physician and urges an expansion of public health work.

While the work as a whole represents a contribution in a much needed field, it is impossible to avoid the feeling that a wider and closer knowledge of recent developments in medical economics might have improved the work and enabled the author to avoid many inaccuracies. There is a bibliography attached with comments that clearly show the bias of the author.

Manual of Medicine By Sir Stanley Woodward CMG CBE MD Physician and Lecturer on Medicine Westminster Hospital Fourth edition. Cloth. Price \$5 Pp 618 with illustrations New York & London Oxford University Press 1935

The author in one small volume discusses the following general subjects: diseases of the alimentary system, diseases of the kidneys, diseases of the respiratory organs, diseases of the circulatory system, diseases of the blood, the deficiency diseases, diseases of metabolism, diseases of the nervous system, and infectious diseases. In view of the fact that the book is intended to be a manual of medicine, the author has succeeded very well. In this edition he has made eliminations and additions. Under the subject of obesity page 320, for example, he suggests the dietary treatment, pointing out numerous food articles that the patient should avoid, emphasizing regular systematic exercises, and closing with the statement that with due precautions thyroid,

from 3 to 5 grains (0.2 to 0.3 Gm) is given three times a day, especially if the basal metabolic rate is diminished. Fortunately, under the discussion of treatment he does not mention alpha dinitrophenol.

Human Physiology By F. R. Winton M.D. Reader in Physiology University of Cambridge and L. E. Bayliss Ph.D. Lecturer in Biophysics University of Edinburgh. Foreword by C. Lloyd Evans D.Sc. F.R.C.P. F.R.S. Jodrell Professor of Physiology and Fellow of University College London. Second edition. Cloth Price \$4.50 Pp 627 with 291 illustrations Philadelphia P. Blakiston's Son & Co. Inc. 1935

In this edition the same high standard of scientific accuracy and fundamental approach has been maintained as in the first. A good deal of material has been added, including many recent contributions to the subject. The sections on circulation, respiratory function of the blood, carbohydrate metabolism, muscle chemistry, the eye and the ear have been contributed to this edition by experts in these fields. Uniformity with the rest of the work has, however, been achieved, and there is a minimum of duplication. The bibliography is restricted to monographs and review articles in most instances. The book therefore is not of great use in looking up the literature of the subjects discussed. There is, however, an exceptionally complete index. Barring one or two of the more encyclopedic works, this is the most critical and reliable textbook now available for students of human physiology.

Die physiologischen und physikalischen Grundlagen der Hautthermometrie Mit einem Anhang über weitere physiologische Temperaturmessungen. Von H. v. Doz. Dr. med. H. Pfälderer und Dr. phil. K. Büllner. Mit einem Geleitwort von Prof. Dr. A. Schliötenheim. Paper Price 4.90 marks Pp 52 with 10 illustrations Leipzig Johann Ambrosius Barth 1935

In view of the increasing practical importance of measurements of skin temperature, it is useful to have available in monograph form a rather critical analysis of the various methods in use, and a discussion of the influence of various environmental factors on skin temperature in normal and pathologic individuals. In the short treatment given, the references to clinical literature have been made brief and, in some respects, inadequate. The important underlying physical and physiologic principles have, however, been carefully outlined. The monograph should therefore be of interest and value to any one undertaking practical work involving skin temperature measurements.

Maimonides (The Rambam) The Story of His Life and Genius By Dr. J. Münz. Translated from the German with an Introduction by Henry T. Schlinkkind Ph.D. Centennial edition. Cloth Price \$1.50 Pp 238 Boston Winchell Thomas Company 1935

This gives in an interesting manner the story of the life and genius of the twelfth century philosopher, scholar and physician. Born in Cordova in 1135, Moses Ben Maimon was at 13 exiled from Spain through anti-Jewish persecution and, after traveling for a number of years in northern Africa and Palestine, settled finally in Egypt, where he became famous as a philosopher, teacher, writer, scholar, judge, astronomer, scientist, statesman, rabbi and physician. This book treats principally of his contributions to philosophy and rabbinic literature. His principal works were "Mishneh Torah," a code and simplification of the Talmud, and "The Guide to the Perplexed," a philosophic treatise in which he aims to harmonize science, religion and philosophy. The chapter on Maimonides as a physician, although rather short, reveals to an extraordinary degree his thorough knowledge of the medical science of his time and deals with his contributions to dietetics, hygiene and treatment, many of which were far in advance of his time. The translator, as well as the author, have proved that the story of a medieval genius can be made as interesting as a present-day novel.

Précis d'histologie. La cellule les tissus les organes. Par A. Branca et J. Verne professeurs à la Faculté de médecine de Paris. Cloth Price 65 francs Pp 631 with 420 illustrations. Paris Masson & Cie 1934

This presents a concise description of the microscopic structure of the body. There are numerous black and white illustrations, the great majority being originals, some of which have been frequently borrowed by other authors from earlier editions of Branca's textbook. A better grade of paper would show them to better advantage. The text has been brought down to date and includes most of the important advances in histology and the attempts to correlate known functions with the minute

structure of the organs. Because of the relatively brief text, many questions are answered with a positiveness which does not reflect the actual state of existing knowledge. The new chapters on the living cell and the trends in histologic investigation are quite interesting. The volume constitutes a concise, accurate, modern textbook of histology.

Corazón y vasos. Por el Doctor Pedro Cosío. Jefe de la sección cardiología del Instituto argentino de diagnóstico. Biblioteca de semiología para médicos generales y estudiantes. Boards. Pp 385 with 266 illustrations. Buenos Aires. El Ateneo. Librería científica y literaria. 1933.

The textbook *Heart and Vessels* was written for the medical student and the general practitioner. It is well printed, is accurately indexed, and contains many illustrations. The introduction contains the system of diagnosis and classification of heart disease advised by the American Heart Association. The material covered includes cardiac anatomy, physiology, pathology, history taking, examination of the cardiovascular system and the various instrumental methods of cardiac investigation. The chapter on x-rays and electrocardiography are particularly well organized and illustrated. The material in the text is concisely and accurately written and meets the purpose for which the author designed the work.

Medicolegal

Malpractice Injury to Ureter During Hysterectomy, Privileged Communications Statute Applicable to Patient in State Institution.—The physician-defendant performed a supravaginal hysterectomy on the plaintiff, removing the upper two thirds of the uterus. During this operation the plaintiff claimed, the defendant negligently injured the left ureter, "resulting in causing an opening in said ureter above the bladder which now permits the urine to pass into the cervix stump where the injured portion of the ureter is now fastened, thence through the vaginal passage." Two operations performed by the defendant to correct the condition afforded no relief. In one of these operations, according to the plaintiff's charges, the intestine was lacerated, causing an opening through which gas and fecal matter passed uncontrolled into the vaginal passage and out with the urine. The patient sued the physician for malpractice. Shortly thereafter she was committed to a state institution for the insane and her guardian was substituted as party plaintiff. There was a judgment against the physician and he appealed to the Supreme Court of Kansas.

Evidence that shortly after the anesthetic was given in the first operation the physician-defendant threw a knife across the operating room was properly admitted, said the Supreme Court, as bearing on the question of negligence. During the trial a physician witness was asked whether, assuming certain facts to be true, the physician-defendant used the ordinary skill and care which surgeons practicing in the vicinity used in like operations. The witness replied, "Well, with these assumptions he did not." This testimony said the court did not trench on the province of the jury but was rather a statement of fact from which the jury might find negligence. The trial court did not err in refusing to permit two physicians on the staff of the state institution to testify. In Kansas, a physician may not testify without his patient's consent, concerning any communication made to him in his professional capacity by his patient or concerning any knowledge obtained by a personal examination of the patient. By the great weight of authority, said the Supreme Court, the fact that a patient is an inmate of a state institution does not deprive the patient of the protection of the privileged communications statute with respect to any information acquired by a member of the professional staff of that institution in treating the patient. The defendant contended that the privilege of the statute if any existed was waived when the husband testified concerning the physical and mental condition of his wife. In holding that there had been no waiver, the Supreme Court relied on the case of *Metropolitan St Ry Co v Jacoby* (C C A) 112 F 924, wherein it was held that the fact that the plaintiff in an

action for personal injuries introduces the testimony of physicians who attended him, with respect to the nature and extent of such injuries does not operate as a waiver of the right to object to the testimony of another physician, called by the defendant, who had attended him for the same injuries, but at a different time. In the present case, continued the court, with the exception of a statement in a hypothetical question, that the patient had been confined in the state institution, there was nothing in the record concerning anything that happened at the institution.

For the reasons stated, the judgment in favor of the plaintiff was affirmed.—*Linscott v Hugbanks* (Kan), 37 P (2d) 26

Autopsies Coroner's Right to Perform.—Kingsley was found dead in his car in a garage in Hennepin County, Minnesota. A deputy coroner of that county directed the undertaker, called by the deceased's wife to take charge of the body, to take the body to the county morgue. There the deputy coroner called a physician to perform an autopsy. The cause of death was found to be "monoxide gas poisoning." The wife was apparently not told that an autopsy was to be performed and did not learn of it until three weeks later. She then sued the deputy coroner, the undertaker, and the physician who performed the autopsy. A verdict was directed in favor of the defendants and from an order denying a new trial, the plaintiff appealed to the Supreme Court of Minnesota.

A wife said the Supreme Court, has a legal right to the possession of the dead body of her husband for the purpose of a decent burial and a wrongful mutilation of the corpse entitles her to damages against the wrongdoer. Her right, however, may be subjected to statutory regulation in the interest of public welfare. The coroner or deputy coroner of Hennepin county is required by statute to investigate all cases of "violent, mysterious and accidental deaths, including suspected homicides" and may order an autopsy when deemed proper. The death of the plaintiff's husband, said the court, undoubtedly came within the class of deaths the coroner was required by law to investigate and he had for the purposes of such investigation exclusive control of the body. The plaintiff contended, however, that an autopsy is authorized only as an incident to an inquest and that under the Minnesota law coroners may hold inquests "upon the dead bodies of such persons only as are supposed to have come to their death by violence." If on investigation, the coroner deems a death accidental, he cannot hold an inquest. But, said the court, an autopsy may be the surest and most satisfactory way of determining that the death was accidental and, since the law provides that the coroner "shall order an autopsy when and where he deems proper" the conclusion is inescapable that the coroner may, as an aid to his investigation, order an autopsy. Furthermore, a coroner is required by law to make out a death certificate and to state therein the cause of death. To do so accurately, he may consider it necessary to have an autopsy performed. He may not arbitrarily order an autopsy when a properly conducted investigation has disclosed the cause of the death. It cannot be made to satisfy an idle curiosity or for the information of some interested insurance company.

The fact that the plaintiff was not informed that an autopsy was contemplated does not tend to prove an arbitrary exercise of the coroner's discretion. A public official is entitled to the presumption that in the performance of his duties he acts in good faith according to his best judgment. In the opinion of the court, the plaintiff's evidence was not sufficient to support a verdict that there was abuse of discretion in ordering an autopsy. A verdict was properly directed, therefore, in favor of the deputy coroner. Likewise, the undertaker was rightly entitled to a directed verdict, for, in taking the body to the morgue, he acted for the deputy coroner. The defendant physician who performed the autopsy must also, said the court, be held free from liability. Although the plaintiff contended that the autopsy went further than was necessary, the testimony was to the effect that it was performed in the usual way. It is almost self evident, said the court, that a proper autopsy to establish a cause of death not only should show a cause but should exclude all other supposable or possible causes. The plaintiff proved no excess mutilation nor any failure to replace

all organs examined, and the burden was on her to sustain the allegations of the complaint in respect to these matters

The Supreme Court, therefore, affirmed the order of the trial court denying a new trial to the plaintiff—*Kingsley v Forsyth (Minn.)*, 257 N W 95

Malpractice Negligent Treatment of Fracture—The patient sustained a fracture of both bones of her right forearm, a comminuted fracture through the upper third of the ulna and a complete, oblique fracture through the neck of the radius. A deformity followed, with a 50 to 75 per cent limitation of motion in pronation and supination but with practically normal motion in flexion and extension. The patient sued the physician defendant, and from a judgment in favor of the plaintiff for \$5,950 the defendant appealed to the St. Louis court of appeals, Missouri.

The defendant complained of an instruction given by the trial court to the jury that the terms "carelessly" and "negligently" do not imply lack of skill or capacity but simply a disregard of ordinary care and caution, that if the jury found the defendant careless and negligent, the fact that the defendant may have been competent and skilful would not constitute a defense. This instruction, said the court of appeals, was correct. Malpractice may result either from injury occasioned by the physician's want of requisite knowledge and skill or from injury caused by the failure of the physician to exercise due care in the application of his skill and knowledge. The present case was founded solely on the theory of negligence and not on the theory of lack of knowledge and skill. Consequently, the question of lack of skill was not an issue in the case and his possession of the required skill, if he did not apply or use it, would constitute no defense.

During the trial the plaintiff called as an expert witness a physician whose office had been closed for twenty years but who had continued a small general practice. He had treated at least one fracture during that time. The defendant contended that this witness was not qualified to testify as an expert with respect to fractures. The court of appeals held that the witness was competent to testify, the limited scope of practice of the witness having a bearing only on the weight to be accorded his testimony.

In the opinion of the court, the verdict was excessive. A physician is liable only for the damage or injury caused by his malpractice and not for the results of the patient's original injury or illness. The plaintiff argued that if the fracture had been properly treated there would have been no ensuing impairment of function of the arm. There was medical testimony, however, that sometimes such fractures as those from which the patient suffered cannot be reduced regardless of the method of treatment adopted, and that such fractures are not commonly reduced in perfect apposition but only in useful apposition. In view of this testimony, the court believed that the verdict more nearly represented compensation for the patient's original injury than for the results of the physician's malpractice. Conditioned on the remittance by the plaintiff of the sum of \$2,950, the court reversed the judgment of the trial court and remanded the case with directions to enter a judgment against the defendant for \$3,000—*Gunter v Whitener (Mo.)*, 75 S W (2d) 588

Health Insurance "Continuously and Actually Confined Within the House" Construed—The defendant insurance company promised to pay certain benefits if the plaintiff suffered a confining illness, which required him to be "necessarily, continuously, and actually confined within the house, and therein regularly visited by a legally qualified physician." During the period from Jan. 20 to Dec. 3, 1931, the plaintiff underwent two operations to relieve a prostate involvement. He claimed that for the period named he was, within the meaning of the policy, continuously confined within his house. He obtained judgment under the policy in the trial court, and the insurance company appealed to the Supreme Court of Nebraska.

The insurance company conceded that the plaintiff had been continuously confined within his house from January 20 to March 26 but contended that thereafter he suffered a non-confining illness. In support of this contention, the company presented evidence that on March 26 the plaintiff had been taken from his home to a bank, at which he had been book-

keeper, to explain certain matters to a depositors' committee, and that on a subsequent occasion he had again been taken to the bank on another matter. There was no contention that the removal of the plaintiff to a hospital and back to his home, on two occasions, broke the continuity of his confinement "within the house." The cases directly in point, said the Supreme Court, are hopelessly in conflict. The court, however, expressed itself as impressed with the following language used in *Garvin v Union Mutual Casualty Co.*, 207 Iowa 977, 222 N W 25, 61 A L R 633:

Strictly and continuously confined within the house in its most literal interpretation would require that the injured stay constantly within the four walls of the house. Such an interpretation would prevent recovery if an emergency such as a fire should arise, and the insured be removed from the house. It would preclude recovery in the event of transportation in an ambulance to a hospital even for emergency treatment. It would bar recovery if the insured sat upon an uninclosed porch of the house or slept upon a sleeping porch that was not inclosed within the house. Such narrow and limited construction should not be adopted in the interpretation of contracts of this character.

In the present case, continued the court, the plaintiff was suffering from a serious illness. He suffered great pain, and hypodermics were frequently necessary during all this period. He was actually within the house except on the occasions noted and most of the time he was in a bed or on a couch. The seriousness of his illness is important only as throwing light on the question as to whether or not he was continuously confined. On the two occasions when the plaintiff was taken from the house, he performed no service except that of imparting to others information which was peculiarly within his own knowledge. The trips were made, not for his own interest or pleasure, but to assist others. To terminate his insurance under these facts would be to penalize him for making an extraordinary effort. The Supreme Court was unable to find any reversible error in the record and consequently affirmed the judgment of the trial court.—*Mackprang v National Casualty Co (Neb.)*, 257 N W 248

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to *THE JOURNAL* in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Spindle Cell Epidermoid Carcinoma.—In the experience of Martin and Stewart, spindle cell carcinomas have not been radiosensitive. The heaviest doses of radon implants have failed to produce sterilization of the bed of the tumor and have permitted recurrences after the main bulk of the tumor has undergone radionecrosis. In many instances the local setting renders local excision by the scalpel a difficult or impossible procedure, owing to the scarred, inelastic and relatively avascular character of the tissues in which the tumors arise. In other cases the growth may be attached to underlying bone, and in these the actual cautery and endothermy at once suggest themselves as the most feasible method of surgical extirpation. In the authors' cases the use of these cautery methods has invariably been followed by local recurrence or by the development of a new tumor. It has seemed to them that, since the growth invariably arises in scarred tissues, any cautery method, by exciting the fibroblastic activity of the tissues, might be responsible for the development of an entirely new tumor in an area condemned to carcinogenesis, even though the one already existent has been destroyed. If the lesion is movable over underlying structures, surgical excision of the local tumor is undoubtedly the treatment of choice. All the patients now living and free of disease in the series of eight cases had wide local excisions. Local excisions failed to cure and were followed by repeated local recurrences in five cases and by metastases in three of these. If the growth infiltrates widely in the subcutaneous tissues the authors recommend a far wider local removal than would be considered necessary in other forms of epidermoid carcinoma. Block dissection of the regional lymph nodes should be done if there are palpable metastases although probably the procedure is of little value after metastasis has occurred. Prophylactic dissection of the regional lymph nodes seems to be both illogical and useless.

Follicle Stimulating Factor Determinations in Cases of Teratoma Testis.—Cutler and Owen made quantitative determinations of follicle stimulating factor (prolan A) on the

urines of sixty-six patients suffering from teratoma testis. The amount of the substance varied between 50 and 16,000 mouse units. Thirteen normal men and patients suffering from benign lesions of the testicle were examined for follicle stimulating factor excretion in the urine. In all the amount was below 50 mouse units per liter of urine. The evidence supports the view that patients suffering from teratoma testis excrete about 50 mouse units of follicle stimulating factor per liter of urine, giving to this test a diagnostic value. In general, a marked diminution in follicle stimulating factor excretion following irradiation is accompanied by pronounced regression of the disease and an improvement in the general condition of the patient whereas failure of the follicle stimulating factor to diminish or an increase in follicle stimulating factor excretion following treatment is paralleled by a failure to respond to therapy. Local recurrence is often preceded by a rise in the quantitative excretion of follicle stimulating factor in the urine, rendering the test of practical value in the follow-up control of this group of patients. The total twenty-four hour urine output should be determined and taken into consideration when the quantitative determination of follicle stimulating factor is estimated under conditions in which clinical conclusions are to be based on smaller variations, in order to avoid errors that might arise as the result of differences in fluid intake. A modification of Doisy and Katzman's benzoic acid method is presented, rendering the test more accurate in cases showing smaller quantities of follicle stimulating factor and preferable in cases in which the urine contains toxic products.

Origin of Uterine Fibroids.—Witherspoon offers pathologic and clinical evidence to support a hypothesis that there exists a cause and effect relationship between the unopposed and persistent action of the estrogenic principle produced by multiple follicle cysts of the ovaries, on the uterine endometrium and myometrium, and the production of (1) immediate endometrial hyperplasia and, provided the stimulation is sufficiently prolonged, (2) more latent uterine fibroids. Since this estrogenic principle affects the genital tract as a whole and also controls the development of the mammary glands, it would appear that this hormone stimulation is the initiating factor in the production of endometriomas and fibro-adenomas of the breast. He studied forty-four cases of endometrial hyperplasia. In each case a curettage was performed and the diagnosis made microscopically. In no case either by bimanual examination or with the curet, was a uterine fibroid observed. In addition, in twenty of the cases a laparotomy was performed for other reasons. In no instance was a fibroid found, but multiple follicle cysts of the ovaries were observed in every case. After varying intervals, an average of four years and nine months, all forty-four patients returned for a second operation, this time for multiple uterine fibroids. The histologic observations in the endometrium, myometrium and ovaries are offered as evidence of an interrelationship between the multiple follicle cysts of the ovaries, endometrial hyperplasia and uterine fibroids.

Malignant Hemangioma. B. Markowitz. Bloomington. Ill.—p. 333.

Test for Demonstrating Sickle Cells.—Beck and Hertz describe a test for the demonstration of sickle cells, which consists of fixing the erythrocytes with formaldehyde after they have been allowed to assume their characteristic form in a test tube sealed with oil. It is also a convenient method for producing large numbers of sickle cells for demonstration purposes and for preparing permanent stained mounts. One or two drops of blood are collected in a test tube (4 by 1 cm.) containing physiologic solution of sodium chloride and 3 per cent solution of sodium citrate. The tube is inverted and the

mixture is shaken. It is covered with sufficient oil to make a layer 1 cm thick. The preparation stands at room temperature for twenty-four hours, whereupon from 0.2 to 0.5 cc. of formaldehyde solution is introduced beneath the oil layer by means of the formaldehyde pipet. This is thoroughly mixed by forcing the liquids in and out of the pipet several times. The oil layer should not be broken for fear of letting air in too soon. Two or three minutes or more should be allowed for fixation. After this period the suspension is mixed again with the formaldehyde pipet to ensure a uniform distribution of cells. A few drops are removed from the tube, the excess oil is wiped from the tip and a drop is placed on a glass slide, covered and examined. The percentage is calculated in the manner of the differential leukocyte count. Permanent preparations are made from the suspension on coverglasses like an ordinary fresh blood film. The smears are dried in air and fixed by flame. Thirteen individuals with the sickle cell trait were found in a group of 100 Negroes examined by the sealed tube method, while only nine were found by the sealed smear method. In the nine sealed smear preparations, no observations were similar. The proportion of sickle cells in the series varied from 3 to 85 per cent, with an average of 26 per cent. In the tube preparations there were five instances of 98 per cent sickling, and in eleven of the thirteen cases the number of sickle cells varied between 85 and 99 per cent. The total number was more than four times that found in the same group by the slide method. The average for the thirteen cases was 77 per cent. Indeterminate cells were found more frequently in the slide preparations than sickle cells, and commonly in greater numbers. They were found in ten smear preparations and in only two tube preparations. The total number obtained by the slide method is more than five times as great as that found by the tube method. In nearly every slide preparation the number of erythrocytes was greater than that in the corresponding tube preparation of the same blood. The total number of apparently normal cells obtained by the slide method is more than twice that found by the tube method.

Buffer Capacity of Pancreatic Juice—Hoerner experimented with the properties of the pancreatic juice collected from pancreatic fistulas. He titrated 1 cc. of the secretion with 1 cc. of tenth normal hydrochloric acid a drop at a time, and the change in pH with each minute addition was determined. Samples of pancreatic juice were collected at half-hour intervals during fasting and after the ingestion of protein, carbohydrate and fat test meals. The fluctuation in the buffering capacity during the eight-hour period of observation was determined. A continuous secretion of pancreatic juice was noted at all times, provided there was no infection or leakage present. Protein diets stimulated a greater flow of secretion than the other test meals used. The amount of secretion depended

largely on the size of the animal and the kind and quantity of food ingested. The buffering capacity of the pancreatic juice reached its maximum from one to three hours after the ingestion of food and gradually diminished as the acidity in the duodenum decreased. The secretion was always alkaline and possessed slight buffering power during fasting. When the buffering capacity was highest, 1 cc. of pancreatic juice was capable of practically neutralizing an equal quantity of tenth normal hydrochloric acid.

Agglutinin Response to Typhoid Vaccine—According to Valentine and her associates the rise in the agglutinin titers of the blood serums of rabbits and human beings, following the percutaneous administration of typhoid vaccine, paralleled the number of treatments and the size of the dose. The human subjects gave small rises in agglutinin titer after a large num

ber of rubbings, the rabbits with a greater number of rubbings, larger doses and a relatively greater rubbing area gave good agglutinin titers. Intracutaneous injections of typhoid vaccine in weekly doses of 50, 100 and 150 million bacilli produced as great an agglutinin response as subcutaneous injections of 100, 200 and 300 million or 250, 500 and 1,000 million bacilli. Intracutaneous injections of 25, 50 and 100 million bacilli produced slightly less response. No appreciable systemic reactions and only slight to moderate local reactions followed the intracutaneous injections. Subcutaneous injections in doses of 100, 200 and 300 million bacilli, even 250, 500 and 1,000 million produced some local and constitutional reactions, but much less than is commonly found with the standard subcutaneous doses of 500, 1,000 and 1,000 million. Oral administration of three different preparations of mixed typhoid-paratyphoid vaccines without preliminary bile treatment produced no significant rise in agglutinin titer when tested one month after ingestion. The results suggest the greater use of the intracutaneous method to obtain immunization.

Mesenteric Thrombosis.—Donaldson and Stout confine their remarks to the less clearly understood venous type. Since venous mesenteric thrombosis may occur as a complication of various conditions, the picture may be complicated by various pathologic elements. Generally, however except in that type of venous mesenteric thrombosis initiated by sudden volvulus or intussusception the onset and course would seem to be relatively slow and initiated by pains of a colicky nature. A striking symptom is the disproportion of the abdominal tenderness and the duration of symptoms to the abdominal rigidity. The abdomen is usually widely and definitely tender to deep palpation and the abdominal rigidity is not nearly as marked when the possible duration of the complaint and the definite tenderness are considered. The normal leukocyte relationship is moderately disturbed in the early stages but is markedly distorted later. An engorged intestinal wall may or may not be felt as a palpable mass. Occult blood is uniformly present in the stool and bowel movements continue, dark and soft to liquid in nature. Coffee ground-like vomitus may supervene. The temperature range in the uncomplicated picture is low. Intestinal obstruction, appendicitis, peritonitis, peptic ulcer, lead colic, simple enteritis, cholecystitis, gastritis and typhoid are among the diseases most likely to be confused by the expert. Arterial thrombosis is much more rapidly fatal than the venous type, which is probably compatible with recovery without surgery in a certain percentage of cases. The authors believe it is possible in a goodly number of cases to recognize mesen-

teric thrombosis and that the type, venous or arterial, may be identified at times preoperatively. They feel that a better understanding and closer inspection by the pathologist and the surgeon of cases of venous mesenteric thrombosis will lead to the more frequent pathologic diagnosis of hemorrhagic infarction of the intestine rather than to the diagnosis of "gangrene."

Complete Procidentia in the Aged.—Liccione is of the opinion that for complete procidentia in the aged no operation is as successful as that of Lefort. The prolapse must be reducible. If reducible, bed rest and topical applications will so soften the presenting mass as to reduce it. It is imperative to clear up all decubitus ulcers prior to operation so as to ensure primary union. Local or spinal anesthesia is preferable. The principle involved is the denudation and subsequent coaptation of rectangular areas on the anterior and posterior vaginal walls, respectively, thus creating a wide median supporting bar, above which rests the cervix. This bar is about 4 by 8 cm. in the average case and forms an effective support for the cervix and uterus. To each side of this median bar is a small canal, which is completely invested by vaginal mucosa and which carries off any cervical secretion. A high perineorrhaphy completes the operation and is a necessary part of it. A preliminary curettage is done to preclude fundal malignant changes. Erosion or ulcer of the cervix is taken care of by cautery or amputation.

Fatty Infiltration of Urinary Bladder.—Saphir and Shapiro observed fatty infiltration (lipomatosis) of the urinary bladder during the histologic examination of a patient who had died as a result of spontaneous rupture of this organ. The histologic sections revealed that muscle bundles had been replaced by fat tissue. The fatty infiltration was characterized by the formation of an abundance of subperitoneal fat, which extended into the musculature of the urinary bladder and occupied the usual position of the muscle fibers. Apparently the urinary bladder that is the seat of fatty infiltration may carry on its function as well as the normal urinary bladder but has little reserve power. The urinary bladder that is infiltrated by fat may rupture as a result of apparently insignificant causes. Fatty infiltration of the urinary bladder was found twice among thirty bladders examined.

Cyclic Agranulocytic Angina.—Stephens and Lawrence discuss a case of agranulocytic angina manifested by recurrences at the time of the menstrual cycles. Following bilateral oophorectomy there was a slight change in the picture during a period of one year, after which time no further recurrences occurred. Amidopyrine was taken at times by the patient, but the data do not allow any positive statement as to any causal relationship between it and the cycles of granulopenia. In order to determine whether menstrual periods in normal young women were associated with any comparable changes in the blood picture, the authors investigated the total and differential white blood cell counts of six women over a period of two months including two menstrual cycles. No variation greater than normal was present in the white blood cell counts. The bone marrow manifestations are of interest, since they presented a normal picture. The patient was able to respond to operation by the usual postoperative leukocytosis.

"Eventration" of Right Diaphragm.—Feldman and his associates add a case of right-sided "eventration" to the literature, thus raising the number of reported cases to ten. The diagnosis in the case was made because of the (1) high posi-

tion of the right diaphragm, (2) regular contour of the arched line as seen in the anteroposterior and lateral views, (3) definite, although limited, excursions of the elevated diaphragm, (4) roentgen observations after an opaque meal and after a barium sulphate enema, with the patient in the recumbent position, showing that the arched line was the dome of the diaphragm and not the outline of a distended intestine, and (5) evidence of inactivation of the right half of the phrenic leaf (Hoover's sign). The extruded intestine was situated between the right diaphragm above and the liver below. In this respect the case differs from the reported ones, in which it has been more usual to find the liver high up under the eventrated diaphragm. The patient has no intestine in the right side of the abdomen. Should she ever develop an attack of appendicitis, the symptoms would certainly be atypical and the method of surgical approach would have to be extraordinary indeed. The patient has been under observation for the last few years. She feels quite well. Should she become pregnant again, an abdominal section will be strongly urged before labor sets in.

Arsenic and Epithelioma.—Montgomery states that arsenical keratosis must be regarded as potentially malignant and hence should be included among the precancerous types of dermatosis. Epitheliomas precipitated by arsenic are usually squamous cell epitheliomas, often with microscopic features simulating Bowen's disease, but usually the condition is graded 2 or 3, although clinically the course may not be as malignant as with ordinary squamous cell epitheliomas graded 2 or 3. Superficial epitheliomatosis is a relatively benign disorder, usually having a relatively benign course as compared with ordinary basal cell epithelioma. The treatment is surgical excision or excision by cautery. The lesions are prone to recur following radiotherapy.

Factors Affecting Color of Skin.—Rogin and Sheard made spectrophotometric analyses of the changes in color that took place in three areas of the skin which had been exposed to the same amount of irradiation from an air cooled quartz mercury vapor arc lamp. One area was moistened with oil of bergamot before being exposed to ultraviolet radiation, the second area was moistened with a 10 per cent alcoholic solution of oil of bergamot before irradiation, and the third was treated only by irradiation and thus served as a control. The area used as a control also gave information regarding the course of erythema and pigmentation in the normal skin after ultraviolet irradiation. They found that the use of the spectrophotometer affords an accurate method of recording the changes of color in the skin after ultraviolet irradiation. The initial erythematous reaction of the skin is generally crisis-like in form, but it may also be plateau-like or double crisis-like. The course of the erythema is rhythmic or wavelike in nature and persists over a period of weeks. In the same subject the amount of pigment formed after ultraviolet irradiation is proportional to the degree of the preceding erythema. This statement cannot be made, in the light of the data at hand, when

erythema and pigmentation are compared in different patients after ultraviolet irradiation. The changes in pigment follow a rhythmic course, apparently independent of the course of erythema. There are marked individual variations in the chronology of the waves, which appear during the course of erythema and pigmentation. The hue of the skin after ultraviolet irradiation remains constant. The changes in the redness of the skin after ultraviolet irradiation are due to changes in purity (saturation) of the hue. The presence of chlorophyll in solutions of oil of bergamot was shown by obtaining curves for spectrophotometric transmission that are characteristic of chlorophyll. There was a decrease in the spectrophotometric transmission of solutions of oil of bergamot after ultraviolet irradiation. Oil of bergamot and a 10 per cent alcoholic solution of oil of bergamot applied to the skin before ultraviolet irradiation diminish the effects of such irradiation. Ultraviolet irradiation following applications of oil of bergamot and a 10 per cent alcoholic solution of oil of bergamot to the skin did not produce dermatitis or increased pigmentation in any of the cases studied. The authors suggest that berlock dermatitis belongs to the group of cutaneous reactions of the venenata type and that it is due to an individual hypersensitivity to chlorophyll or adulterants found in the perfume or toilet water that has been applied to the skin.

A Fungus Causing Madura Foot in Canada.—Dowding has grown *Monosporium apiospermum*, which has been isolated for the first time in Canada, on culture mediums and has made a comparison with cultures of the same fungus obtained from Europe. In addition to characters described previously she has observed the following features: 1. The cultures darken from white to cinnamon drab. Unlike the strains obtained in the

United States, they produce no sclerotium. They frequently exhibit a growth of short dark brown aerial hyphae. 2 The mycelium is characterized by terminal and intercalary swellings and "racquet hyphae" resembling the growth forms of many dermatophytes. 3 The form of the conidiophores depends on their habit of growth, when they are submerged in the medium they are undifferentiated from the other hyphae when they are growing in the air they become erect, tapering and dark colored. 4 The sterigmas sometimes occur on the conidiophores in whorls of from two to five. 5 The spores are normally borne singly, but sometimes they collect in groups, when a sterigma produces several spores in succession. *Geomyces* sp., isolated from Alberta soil, resembles certain fungi causing maduromycosis, but it was found not to be pathogenic to an experimental guinea pig.

Kraurosis and Leukoplakia of Vulva—During the last eight years Kearns observed seventeen cases of carcinoma of the vulva, fourteen of which were sectioned and treated. Four of these showed a definite origin in leukoplakia. The chief clinical symptom in all cases of leukoplakia was pruritus whereas in kraurosis the chief complaints were of dyspareunia, soreness and bleeding, and in carcinoma of a tumor of the vulva with pain and bleeding. It is his belief that all cases of kraurosis vulvae have a previous hypertrophic or leukoplakic stage and if this hypertrophy is prolonged a progressive leukoplakia will develop, which will go through the stages of metaplasia and cancer formation. If, however, atrophy ensues the leukoplakia progressively gives rise to kraurosis, and the involved skin becomes thinner and thinner, resembling parchment. The surface becomes dry, scarlike and brittle. The shrinkage in this cicatricial sclerotic tissue produces a stretching of the skin over the nymphae. The latter may entirely disappear, as may also the frenulum of the clitoris. The vestibule of the vagina becomes funnel shaped and narrow, causing dyspareunia and pain on examination, because the diseased skin is easily torn and fissured. Histologically, kraurosis shows an atrophy in all layers of the epidermis especially of the horny layer and the lowest layer. A complete loss of the papilla of the cutis occurs allowing the epidermis and cutis to lie in flat adjacent layers. In the outer and reticular layers of the corium in contrast to the edema of leukoplakia, a homogeneous hyalinized material is seen, which spreads diffusely throughout the subcutaneous tissue, fat, elastic fibers, hair follicles, glands of the hair follicles, sebaceous glands and sweat glands. These structures gradually disappear. If large sections are taken through the vulva these atrophic changes can be seen and connected with remnants of leukoplakic areas. In the hypertrophic or leukoplakic stage pruritus is a common symptom, but in the atrophic stage or kraurosis, soreness and bleeding are the troublesome features. The symptoms of pruritus may be relieved by resection of the perineal nerves in the vulva causing anesthesia of the part but this may obscure hypertrophic changes developing. Painting the surface with a 5 per cent solution of silver nitrate often gives relief. The administration of ovarian extract may help. If the leukoplakic stage persists, resection of the vulva should be done, as from 20 to 25 per cent of persistent leukoplakias will become malignant.

Endocrine Origin of Primary Dysmenorrhea—Witherspoon points out that the most recent explanation of primary dysmenorrhea is an endocrine imbalance. Reynolds has shown that uterine rhythmic contractions become increasingly more active as the graafian follicle develops. After rupture of the follicle and corpus luteum formation, the uterine contractions are inhibited. The pain of primary dysmenorrhea can be explained by the withdrawal of the progestin influence, which results in whipping into marked activity, by the action of the follicular hormone, a uterus that has been lying in a quiescent state for from ten days to two weeks. The rationale of treatment in this condition is to counterbalance the follicular hormone activity by administering the luteinizing principle found in the urine of pregnant women. The method of treatment employed was to inject intramuscularly and daily 250 rat units of gonadotropic principle of pregnancy urine (folliculin-Squibb) from three to four days previous to the expected flow and from one to two days during the flow. Thirteen of seventeen patients so treated for dysmenorrhea experienced relief.

Thrombo-Angiitis Obliterans—Friedlander and her associates determined the significance of the blood volume in thromboangiitis obliterans in twenty-five patients who had had a surgical removal of both ovaries and the uterus and a control group of twenty-one patients. In addition a number of female cats were subjected to bilateral oophorectomy. The cholesterol, fibrinogen and viscosity were selected as factors that might have a bearing on the greater tendency to thrombosis. The average blood volume in the oophorectomized cases showed a reduction of about 25 per cent from the normal. This change became more striking after the first few months. Coincident with this there was an elevation of the cholesterol and fibrinogen of the plasma and an increase in viscosity of the blood. There was a consistent tendency for the cholesterol figures to be higher and they were supported by a diminished blood volume. A normal blood volume was obtained in only one patient who had had a bilateral oophorectomy, who presented a definite clinical picture of hyperthyroidism with a basal metabolism of plus 47 per cent. In the control group all the blood volume figures

were within normal limits and the cholesterol, fibrinogen and viscosity were correspondingly lower. This group included eleven patients with normal menopause and artificial menopause produced by radiotherapy. It would appear, therefore that some substance capable of influencing the blood volume is produced by the ovaries even after other physiologic functions have ceased. The cats subjected to operation showed a consistent tendency toward a reduction in blood volume after bilateral oophorectomy. In one animal, in which only a single ovary was removed, there was no reduction in volume.

Friedman Test for Pregnancy—Mills presents 213 cases in which the Friedman test was used, of which 96.7 per cent have been proved correct by subsequent clinical events. His experience shows that a certain number of false positive results can be avoided by not using rabbits that gave positive results before. A certain number of false negative results can be avoided by not laparotomizing the rabbit but by killing the animal and exposing the ovaries with wide dissection. A certain number of false negative reactions can be avoided also by obtaining a concentrated first morning voiding. If a test should prove negative in a patient who has passed a regular menstrual period only a day or so, it must be borne in mind that the patient may be less than two weeks pregnant and the test should be repeated at a suitable interval. A certain number of errors can be avoided also by examining the ovaries of the rabbit by microscopic section. The test has proved useful in the diagnosis of early pregnancy and differentially in fifteen cases of menopause, seven ovarian cysts including one dermoid cyst, one lutein cyst, one endometrial cyst or chocolate cyst, two pseudomucinous cystadenomas and two cysts of unknown type, two cases of acute pus tubes, three myofibromas of the uterus, and one case of chronic epididymitis (all of which were negative) also in suppressed, delayed and irregular menses, fear of pregnancy, and one case of attempted blackmail. One case of chorionepithelioma was positive. The Friedman test like all other single diagnostic methods should not be relied on exclusively in the diagnosis of pregnancy or other conditions but should be employed only in correlation with a careful physical examination and clinical history of the case.

Hypertonic Solutions of Sucrose—In an attempt to find a nontoxic substance the osmotic action of which in the circulation would not be complicated by adverse sequelae, Masserman investigated the physiologic effects of the intravenous injection of hypertonic solutions of sucrose in thirty-five human subjects. He found that a 50 per cent solution of sucrose is satisfactory for clinical use. When from 300 to 500 cc of this solution is administered intravenously the initial rise of cerebrospinal fluid pressure is of lesser degree and duration than is the case with the dextrose or the electrolytic solutions. Subsequently the desired diminution in intracranial tension is greater and more prolonged. Corresponding to the relative impermeability of the blood-cerebrospinal fluid barrier to sucrose there is only a slight and transient intracranial hypertension as the final hydrodynamic effect of its intravenous administration. In contrast to this, dextrose and most of the physiologic solution of sodium chloride pass readily from the blood into the central nervous system and

the cerebrospinal fluid and thereby induce a marked and prolonged increase in spinal fluid pressure and possibly also an edema of the central nervous tissues. The 50 per cent solution of sucrose when administered intravenously does not cause an overt phlebitis in the injected vein and induces only a mild reaction if allowed to escape in small amounts into the subcutaneous tissues. Comparatively large amounts of sucrose in the circulation are apparently not toxic and cause no serious disturbances in the chemistry or cytology of the blood. Being a disaccharide and foreign to the blood stream, sucrose induces a marked diuresis and is eliminated rapidly in the urine. Since sucrose is thus either completely eliminated or else metabolized in the body only in small amounts, repeated injections may be given when necessary without cumulative adverse effects. As to the clinical use of hypertonic solutions of sucrose for the purpose of reducing the intracranial hypertension in patients with cerebral concussion, in meningitis, and preoperatively in cases of brain tumor, the author states that it must be recognized that the disturbances in cerebral circulation and tissue permeability that obtain in these conditions might modify the osmotic and dynamic effects that he reports in normal subjects. Nevertheless, in view of the ready availability and apparent lack of toxicity of the solutions their administration for their demonstrated decompressive and diuretic effects seems to deserve a careful clinical trial.

Phenolsulphonphthalein Test of Kidney Function in Anemia—Chapman investigated eleven cases of severe anemia that showed no signs of cardiovascular or renal disease. The urine in each case was normal. A fractional phenolsulphonphthalein test of kidney function was done on each patient. The patient emptied the bladder and drank 400 cc of water, and half an hour later 1 cc of phenolsulphonphthalein was injected intravenously. Specimens of urine were then obtained fifteen, thirty, sixty and 120 minutes after the injection. The first two collections show the high initial output of dye, which is the significant feature of phenolsulphonphthalein excretion. The curve of elimination of dye was normal in each case. Anemia alone does not affect the excretion of phenolsulphonphthalein by the kidney.

Fundusotomy in Treatment of Peptic Ulcer—Seely
and Zollinger resected the gastric fundus from four dogs, leav-
ing a tube about 3 cm in diameter from the esophageal opening
to within 6 cm of the pylorus This tube was made up chiefly
of gastric mucosa, smooth and free of rugae An immediate
postoperative drop of both free and total acidities was found
as compared to the preoperative levels There was a gradual
return of the free and total acid, reaching preoperative levels
by the end of eight months The stomach at necropsy showed
hypertrophy to normal size and outline, without reproduction of
rugae Microscopic examination of the postoperative stomachs
showed a rich distribution of active acid bearing cells, especially
along the greater curvature Histologically these cells were
filled with secretory granules and vacuoles, suggesting that they
were actively forming hydrochloric acid The experimental
studies agree with the clinical observation that the gastric
acidity cannot be permanently lowered regardless of the amount
of acid bearing tissue removed Fundusotomy has little to
offer as a means of permanently reducing gastric acidity and as
a possible therapeutic measure in the control of peptic ulcer

**Origin of Excessive Anterior Pituitary-like Principle
of Eclampsia**—The Smiths' quantitative analyses of the serum
and urine for anterior pituitary-like principle and estrogenic
substance in a series of sixty-eight women in the second half
of pregnancy have shown that late pregnancy toxemia and
eclampsia are characterized almost without exception by a
marked excess of anterior pituitary-like principle as compared
with normals A low level of estrogenic compound in a large
proportion of these patients has also been found, but the quan-

titative abnormality of this hormone is less striking and less
consistent than that of anterior pituitary-like principle Both
the placenta and the anterior lobe of the hypophysis are known
to contain gonadotropic factors The authors' experiments were
carried out for the purpose of determining which of these two
sources is responsible for the excess found in late pregnancy
toxemia and eclampsia The serums of women with late preg-
nancy toxemia and eclampsia have been found to have the same
effect on the ovaries of hypophysectomized rats as the serums
of normally pregnant women An extract of human placenta
also had this effect, while hypophyseal anterior pituitary-like
principle caused a follicular and luteal activity not caused by
any of the other materials tested The placentas of toxemic
and eclamptic patients contain excessive amounts of anterior
pituitary-like principle and tend toward low levels of estrogenic
material as compared with the placentas of normal pregnancies
Control tissues from two women who died of eclampsia and
one who miscarried at five months have shown that the liver,
spleen kidney and fetus contain almost no anterior pituitary-
like principle or estrogenic material The authors concluded
that the excessive amounts of anterior pituitary-like principle
previously reported by them in the blood and urine of toxemic
and eclamptic women as well as the tendency toward low levels
of estrogenic substance, have their origin in the placenta They
suggest that a continued overproduction of anterior pituitary-
like principle by the placenta is probably a related factor and
possibly causal in the etiology of late pregnancy toxemia and
eclampsia

Granulosa Cell and Brenner Tumors of the Ovary—
Bland and Goldstein review the available literature regarding
granulosa cell tumor of the ovary and the Brenner tumor
Individual summaries of 160 cases of the granulosa cell tumor
and sixty cases of the Brenner tumor are tabulated These,
together with eighty-five cases of granulosa cell tumor reported
in groups make a total of 311 cases Clinically, the granulosa
cell and Brenner tumors are relatively benign Only occa-
sionally do they break through the capsule, recur or metastasize
The granulosa cell tumor occurs most frequently after the
menopause Seventy of the growths reported developed in
women aged 50 years or more Likewise, it was noted that
the Brenner tumor occurred in thirty-six women well past the
menopausal years Seven cases of granulosa cell tumor, how-
ever occurred in children less than 10 years of age Uterine
bleeding (menorrhagia, metrorrhagia) was the most common
symptom manifested by patients with the granulosa cell tumor
Of the 117 patients in whom symptoms were described, 60 per
cent complained of this symptom The Brenner tumor does not
seem to be associated with conspicuous symptoms Granulosa
cell tumors occurring in children are prone to induce precocious
sexual development A personal case of a granulosa cell tumor
arising in a child 7 years of age, who underwent marked sexual
development is presented Data concerning the final outcome
were available in ninety-six cases of the granulosa cell tumor
and in thirty-nine cases of the Brenner tumor Forty-two
patients with the granulosa cell tumor were reported well for
periods varying from one to ten years after operation, while
twenty patients died at varying periods following operation
Four of these patients succumbed from metastases within one
year after removal of the neoplasm Twenty-seven patients in
whom the Brenner tumor was found were known to be well at
varying periods following operation Six died within one year
after operation One patient of this group died from metastases

Acute Rheumatism and Its Results—Wilkinson states that rheumatic inflammation, whenever it appears, produces a characteristic microscopic lesion—the submiliary focus. It is common in cardiac muscle, pericardium, endocardium, synovial and subcutaneous tissues and is found in the adventitia and media of arteries in all parts of the body. The typical focus shows four distinct points in its structure: a fibrinous matrix, certain large multinucleated cells, plasma cells or fibroblasts and an aggregation of leukocytes—darkly staining mononuclear cells. At first the nodule shows an aggregation of lymphocytes and plasma cells, later the characteristic multinucleated cells appear, and finally the lesion is replaced by a patch of fibrous tissue. These foci are always accompanied by more or less marked changes in the parenchyma of the tissue invaded and produce a considerable degree of vascular proliferation and hyperemia. In the more chronic forms of acute rheumatism the degree of fibrosis of the myocardium may be truly astonishing. It is of the greatest importance to realize that even in the mildest case in which the myocardium is involved the endocardium may escape, when it is damaged, with consequent valvular defect, the lesion is preceded by changes in the valve leaflets, and the valves are not directly infected from the blood in the chambers of the heart. The mitral valve is most frequently, and the aortic valve quite commonly, damaged, while the tricuspid and pulmonary valves are relatively seldom attacked. Damage is the result of both stresses and vascularity. The relatively avascular pulmonary valves, which sustain comparatively little stress, escape, while the vascular and heavily stressed mitral valve is most seriously and most often involved. Newman has calculated that 0.8 per cent of all elementary school children have rheumatic cardiac disease. Coombes showed that about 40 per cent of all heart disease was rheumatic, that the average rheumatic cardiac patient lived to 28½ years and that only 7 per cent of such patients attained the age of 50. He also showed that nearly half the children who acquire rheumatism before the age of 5 years develop serious cardiac damage, while only a fourth of those who develop rheumatism after 10 years of age become cardiac patients.

Clinical Interpretation of Arneth Count—While it is well established that infections tend to produce a shift to the left in the Arneth count, Young observed in the course of clinical work that the count sometimes fails to show this shift in acute infections and that it may show a left handed shift in the absence of infection. Such exceptions to the rule detract considerably from its clinical utility. His observations indicate, however, that the apparent failure to conform to expectation is to be associated with the percentage method of recording the count and that, by expressing it in absolute figures per cubic millimeter of blood, errors in its clinical interpretation can generally be avoided. A normal polymorphonuclear output may occur in the presence of infection, notably in undulant fever. In addition to infections, left handed percentage counts may occur in agranulocytosis and in hypersplenism. Right handed percentage shifts may occur after inflammatory reactions, as well as in certain other conditions. An absolute increase in the polymorphonuclear output is necessary for the interpretation of a count as evidence of infection. An absolute increase in output and an absolute reduction due to accelerated removal are the best evidences of inflammatory activity, but the latter change is not always present.

Effects of Reduced Cooling Powers on Water Balance—Lee and Mulder kept male subjects who had refrained from taking food or water for twelve hours at rest during a period of some six and one-half hours on each of three occasions in a room with different atmospheric conditions. A standard meal and a standard amount of water were administered at stated times. A "basal level" of urinary volume of from 15 to 30 cc an hour was reached during the ensuing three hours in a normal environment. In a hot environment this "basal level" was lowered to from 8 to 15 cc an hour. This is taken to illustrate the limitation of the concessions allowable to hydration functions at the expense of excretory functions. It was possible to differentiate two fairly constant variations in sweat excretion: (1) a low initial rate and (2) a burst of sweating after water consumption. Psychic factors exert a strong influence on sweating. There is a definite burst of sweating, often profuse in amount, when water is swallowed. This appears to be partly reflex, partly absorptive in origin. The total amount of sweat lost bears a marked relationship to the humidity of different environments of fairly equivalent "effective temperature." The difference in dehydrating power of the dry and humid environments was reflected in the maximal change in serum protein percentage, which in the hot wet room was little more than half (77 per cent) that in the hot dry room (113 per cent).

The blood serum among other body fluids bore a disproportionate amount of the total dehydration (i. e., after six hours of exposure). This disproportion was greater in the hot wet than in the hot dry environment. There was some confirmation of the observation that the cutaneous chloride excretion increases with the length of the exposure, at least during the first four hours. The average concentration in the sweat was low (from 0.2 to 0.25 per cent). Under the conditions of these experiments there was no inability on the part of the body to retain a liter of administered water.

Alkalosis Arising in Treatment of Peptic Ulcer W. Oakley—p. 187

Alkalosis Arising in Treatment of Peptic Ulcer—Oakley believes that alkalosis often passes unrecognized. He has collected from the wards of a general hospital seven cases in which treatment was being given for peptic ulcer which show the necessity of keeping in mind the possibility that alkalosis may develop in any patient taking alkalis regularly even in moderate doses. Although the dosage of alkali does not vary greatly in the different wards, five of the cases were diagnosed by one physician or his assistants. It is therefore probable that many cases pass undiagnosed either to recovery or (more probably) to death. Six of the patients were men. Symptoms are numerous and varied, the most characteristic are anorexia, headache, irritability and changes in mentality, nausea, vomiting, aching pains and twitching in the muscles of limbs and weakness, which may amount to prostration. Flushing and perspiration may be present, in severe cases slow respiration rate, rapid pulse, tetany and even fits may precede the onset of coma, which is usually fatal the patient dying uremic. The tongue is dry and furred, and apart from muscular tenderness and urinary changes, the principal signs are those of increased neuromuscular excitability, these include brisk reflexes, muscular twitchings and occasionally latent or frank tetany with carpopedal spasms. Incontinence may complicate severe cases. The urine is typically increased in amount and alkaline in reaction and contains protein and granular and hyaline casts, red and white blood cells being observed less constantly. The urine may resemble that of acute nephritis. In any suspected case all alkalis should be withheld and the alkali reserve and blood urea estimated. If these are raised acid should be given in the form of ammonium chloride (from 1 to 1.3 Gm.) or acid sodium phosphate (from 2 to 2.6 Gm.) three times a day after food, until the alkali reserve which should be estimated daily, has returned to normal limits. The protein intake should be limited to about 40 Gm a day and all food given should be in fluid or semisolid form, careful attention being paid to the condition of the mouth and intestine. When treatment is given along these lines, recovery should occur in all but the most severe cases, but symptoms such as pains in the legs, may persist for several weeks. It is unwise to perform any operation until the blood urea has been normal for some days.

*Urgent Indications for Operation in Recent Closed Traumatic Lesions of Skull and Brain A. Jentzer—p. 23

Intercostal Radicular Anastomosis to Vertebral Traumatism with Section of Lumbar Medulla A. Chiasseroni—p. 54

Traumatism of Skull and Brain—Jentzer discusses the effect of operation in cranial traumatism based on the records of 837 cases from 1914 to 1934. There were 366 patients with cerebral contusion who recovered under nonoperative treatment. Seven died in spite of conservative treatment and two in spite of operative intervention. Two hundred and thirty-three patients with cranial fracture recovered under conservative treatment, thirty-nine with fracture recovered after operation, thirty-five died in spite of operation and seventy-three died without operation. There were eighty-two cases of fracture which could not be used for various reasons. From the study of these cases he concludes that the anamnesis can never be sufficiently complete to dictate the therapeutic procedure. In more than 50 per cent of the fractures, some of a severe character, such as slow pulse and hyperpyrexia, recovery occurred without intervention. Indications for operation are given by the succession of physiopathologic phenomena rather than by any one set of signs. In the severe cases, immediate operation is indicated. This is based on the enormous anatomic lesions observed in 117 necropsies. Such lesions could not be expected to heal without surgical help. In some microscopic traumatism develop toward neurologic sclerosis. The changes in the choroid plexus, the different effects of hemorrhage, the sympathetic disorders (congestion edema, anemia) and the silent lesions might all be helped by early trephining. The author concludes that death is not produced by lesions of the hemispheres alone, of the protuberance of the peduncle or of the bulb and by hemorrhages, but that cerebral edema, pulmonary lesions and emboli are common fatal complications.

Relation of Nodose Rheumatism to Juxta-Articular Nodules—According to Bollag nodose rheumatism is characterized by painless, easily recognizable subcutaneous nodules that vary in size from a lentil to a pea and occasionally are somewhat larger. Though most reports agree that these nodules are usually near the joints similar formations have been observed also on tendons cranium, ribs tibia and pelvis and in other locations. Moreover, nodules on certain internal organs such as the myocardium and the pericardium, have likewise been brought into relation to nodose rheumatism. In this connection the author calls attention to Aschoff's nodules which are found in rheumatic myocarditis but which, according to some investigators may also be classified with nodose rheumatism. In studying the problem of nodose rheumatism, it will be noticed that in the dermatologic literature, or in the literature on tropical diseases, juxta articular nodules are likewise described. The author points out that in recent years it has been discovered that the so-called tropical juxta-articular nodules are really not a tropical disorder but are of syphilitic nature. The clinical aspects of these syphilitic (dermatologic) juxta-articular nodules do not differ greatly from those of the nodules that are characteristic for nodose rheumatism, but most investigators agree that the two conditions have to be differentiated. The author gives the clinical history of a woman, aged 28 who suffered from recurrent swellings of the joints and in whom nodules were detected on both wrists and behind the ear. The patient had typical Hutchinson's teeth and the Wassermann reaction was once weakly positive, while

later controls were negative. Later, nodules were detected also on other parts of the body. Treatment with a gold preparation improved the articular function and reduced the pain in the joints, and the nodules gradually disappeared. The author points out that the differential diagnosis is extremely difficult in this case, for the nodules may be a manifestation of nodose rheumatism in a person with congenital syphilis or they may be juxta-articular nodules. He emphasizes that, in studying juxta-articular nodules, dermatologists should not overlook the possibility of a nodose rheumatism and internists should not disregard the possibility of a syphilitic nature of the juxta-articular nodules.

Postoperative Contralateral Phlebitis Due to Intervention on Right Side of Abdomen Four Cases V. Bernabeo—p. 1093

Antimony Stimulation of Reticulo-Endothelial System in Estivo-Autumnal Malaria—In a preliminary report, De Nunno concludes that the intravenous injections of antimony and potassium tartrate, given to rabbits in doses corresponding to those used in human beings, provoke a stimulation of the reticulo-endothelial cells that is more marked if the animals are given the largest therapeutic doses that can be given to human beings. Tartarated antimony has the same action on the reticulo-endothelial cells of human beings, as proved by the author by the examination of the splenic pulp before and after its administration. The treatment consists in intravenous injections of a 1 per cent solution of antimony and potassium tartrate given every other day in increasing doses of from 1 to 14 cc of the solution up to a total quantity that varies, according to the more or less rapid disappearance of the plasmodium in the splenic pulp, between 175 and 213 cc for the two courses of injections. The first few injections are followed by a mobilization of plasmodia, which appear in the blood in endoglobular and crescent forms and provoke the development of more or less typical malarial febrile spells. The size of the spleen diminishes from the third or the fourth injection and is normal at the end of the treatment. In fourteen adult patients suffering from estivo-autumnal malaria that had resisted quinine, plasmochin and atabrine treatments, the antimony treatment resulted in the recovery of thirteen. All were carriers of plasmodium praecox, which disappeared from the spleen after the treatment. One patient discontinued the treatment because of intolerance when he had received 162 cc of the solution. By that time the size of the spleen was reduced and recovery occurred three weeks later by the administration of plasmochin and quinine as complementary treatments. The intravenous injection of antimony and potassium tartrate, if given before or during the development of a malarial spell does not control its development. The therapeutic effect of the treatment is due to the action of antimony and potassium tartrate on the reticulo-endothelial system, both by stimulating the proliferation of phagocytes and by acting, after its accumulation in the cytoplasm of the reticulo-endothelial cells, on the phagocytized plasmodia. The author advises the treatment in chronic malaria in order to ascertain its indications and efficacy from its results in groups of patients larger than his group.

Lipoid Nephrosis Case A. N. Accinelli—p. 196

Rheumatic Fever in Painful Valgus Talipes—According to Costa Bertani there is a type of painful valgus talipes of rheumatismal origin that occurs in patients regardless of age. The author reports fifteen cases in which the rheumatismal

etiology was indubitable. The patients ranged in age between 8 and 43. This explanation of the pathogenesis of the condition is the theory of an infectious (rheumatic) arthritis at the tibiotarsal and metatarsal joints, followed by distention of the deltoid and calcaneoscaphoid ligaments and of the muscles and tendons of the internal edge of the arch of the foot, which result in relaxation of Chopart's joint and collapse of the internal edge of the arch. These changes determine the rupture of the normal relations of the joints of the foot and, if the factors of standing or walking are added, a traumatic arthritis develops. Traumatic arthritis is the cause of the contracture and secondary changes that follow. Rheumatic painful valgus talipes may occur from a primary localization of the virus of rheumatic fever exclusively at the heel and the joints of the foot, or as the secondary phase of a painless valgus talipes of rheumatic origin. In either case the mechanism of its production is the same. The author does not believe that standing or walking alone causes painful valgus talipes. Neither does he agree that this type of talipes should be termed "flat rheumatic talipes," because the occurrence of painless flat valgus talipes is frequent, while the feet are never flat in cases of rheumatic painful valgus talipes. By the use of orthopedic arch supports as soon as talalgia (the first symptom of painful valgus) appears the pain disappears, the patient regains his functional capacity and further deformity of the foot is prevented.

Magnesium Chloride in Treatment of Venereal Papilloma and Warts—Fernandez and Capurro advise the administration of intravenous injections of magnesium chloride in the treatment of venereal papilloma and warts. They used a 40 per cent solution of anhydrous magnesium chloride in water or in physiologic solution of sodium chloride, that is, a solution in which each cubic centimeter of the solvent contained 0.4 Gm of the solute. They begin with injections of 0.05 or 0.1 Gm and increase the dose according to the age and tolerance of the patient, if possible, up to 1 or 2 Gm. for each injection in adults. The number of injections varies with the evolution of the disease during the treatment and the reaction of the patient to the drug. After a number of injections, which in the cases of the authors varied from ten to forty, an interval of rest without injections is allowed. Improvement manifests itself during the treatment and generally recovery is completed during the period of rest. This is due to the cytophylactic properties of the drug, which last for some time after the injections are given. If satisfactory results are not obtained from the first series of injections, the treatment may be repeated. The authors report the results of the treatment in a group of twenty-four patients suffering from venereal papilloma or warts. In fifteen patients complete recovery was obtained, five were improved, in four the condition remained unchanged and the rest of the patients did not report for further observation after having received one or more series of injections. Because of the cytophylactic effects of the drug and of the improved condition of the patients when they discontinued the treatments, the authors believe that their recovery was probable.

Water and Mineral Exchanges in Addison's Disease—Marañón and Collazo investigated the following problems in patients with Addison's disease: the content of the blood, the water content of the muscles, the ion content of the blood, the action of adrenal cortex extract on the water and electrolyte content of the blood, the water elimination and the value of sodium chloride in the treatment. They found that in patients with chronic adrenal insufficiency there exists a more or less pronounced dehydration, which is demonstrable in the blood plasma as well as in the muscular tissues. They are convinced

that this dehydration plays an important part in the terminal manifestations of the disease, for it is connected with the severe acidosis that is typical in the last stages of the disease. The causes of the dehydration are supposedly quite complicated. They are doubtless influenced by the loss of glycogen from the liver and also by disturbances in the mineral exchange, the most noteworthy sign of which is a disturbance in the potassium sodium equilibrium, namely, an increase in the potassium ions and a relative decrease in the sodium ions. The injection of adrenal cortex extract produces in these patients an increase in the water retention and aids in reestablishing the disturbed potassium sodium equilibrium. The effect of sodium chloride on adrenal insufficiency in adrenalectomized animals, as well as observations on patients with Addison's disease, induced the authors to give sodium chloride in connection with adrenal cortex extract. The authors found that the addition of sodium chloride counteracts the dehydration, reduces the severity of the symptoms and improves the general condition of the patients with Addison's disease.

Management of and Fatalities in Delivery of Twins in Home C. Holtermann — p 1191

Anesthesia in Small Interventions on Female Genitalia Vilma Janisch Rasković — p 1195

Cause of Arteritis — Braeucker points out that the first detailed description of an arterial inflammation was given in 1879 by von Winwarther, who designated the conditions as endarteritis obliterans. Later several other investigators corroborated the observations made by von Winwarther. Buerger studied vascular inflammations on a large material. He did not place the same stress on the changes of the intima as von Winwarther had done but designated the disorder as thrombo-angitis obliterans because in the beginning stage of the disorder there exists only an inflammation of the vascular wall which is later followed by a thrombosis. The author discusses the histologic aspects of thrombo-angitis obliterans (Buerger's disease) and mentions the various theories that have been advanced regarding the pathogenesis of this disorder. Several investigators have stated that thrombo-angitis obliterans is related to infectious rheumatism, but this theory has been rejected by leading pathologists and clinicians. Some authorities think that the disorder may be caused by different factors, while Buerger believed that it is an infectious disease. To be sure, Buerger did not succeed in finding the causal organism but he succeeded in transmitting the disease and, at any rate, he thinks the disease occupies a unique position, and a number of clinicians are inclined to agree with him. The author points out that from Buerger's disease in the restricted sense of the word there can be differentiated a number of other vascular inflammations, such as those developing in typhus, cholera, scarlet fever and other infectious diseases, as well as those developing after frost bite and traumas. He gives the detailed description of a case in which a vascular inflammation developed after a trauma. The inflammation was localized especially in the external layers of the artery. Thus the anatomic pathologic aspects were not those characteristic for Buerger's disease. Moreover, the clinical symptomatology was not like that of thrombo-angitis obliterans. In addition, the author observed two other cases in which vascular inflammations developed after traumatic injuries. He considers it unjustified to ascribe such posttraumatic forms of arteritides chiefly to constitutional factors. He concedes that such factors may be involved but he emphasizes that the trauma is the most important factor, just as the infection is the most important factor in the forms of arteritides that develop after infectious diseases.

Scarlet Fever Blanching Phenomenon — Gerth and Trautmann, in their discussion of the scarlet fever blanching phenomenon, show that this sign is produced by injecting intracutaneously from 3 to 5 cc. of blanching serum at a

suitable site within the region of the scarlet fever exanthem and watching the results after from six to eight hours. If the outcome is positive, the exanthem disappears over an area varying in size from that of a quarter dollar (24 mm) to that of the palm of the hand. There is evidence that the scarlet fever blanching phenomenon is caused by an immunologic property of the injected blood serum. Although the specificity of the scarlet fever blanching phenomenon is generally accepted there are nevertheless certain aspects that induced the authors to make further investigations of its mechanism. They discuss the so called calcium blanching phenomenon and Glanzmann's assertion that the blanching phenomenon may be positive in exanthems that are not due to scarlet fever. The authors studied the phenomenon in fifty-eight cases, employing blanching serum as well as calcium and giving their attention also to the so-called pseudoblanching phenomenon. In summarizing their opinion of the present status of the scarlet fever blanching phenomenon they state that 1 The scarlet fever blanching phenomenon is a specific reaction. 2 The calcium blanching phenomenon is the result of vasomotor actions of the calcium salt, it is not suited to replace the serum blanching phenomenon. 3 In some instances, undesirable secondary effects of the blanching serum may produce a pseudoblanching phenomenon, that is, a nonspecific reaction in the form of a centrally slightly elevated erythema with a lighter peripheral zone. The authors describe a case in which a pseudoblanching phenomenon developed. In this woman scarlet fever could be excluded on the basis of the anamnesis, the onset and the course of the disease, and the absence of eosinophils from the blood at the most severe stage. The fact that the patient's serum produced blanching phenomena in scarlet fever exanthems was a further proof that the disorder was not scarlet fever; it was found to be a mercury dermatitis.

Circulatory Weakness Following Spinal Anesthesia

Preissecker points out that, although great care is taken to detect an impairment of the heart before spinal anesthesia is decided on there occur nevertheless cases of collapse. This type of collapse is not the result of cardiac failure but is caused by deficiencies in the peripheral circulation, that is it is a vascular shock. The author shows that this vascular shock is probably the result of sensitization to protein, for in women with diseased genitalia, parametritis, tumors of the adnexa, carcinoma or bleeding myomas, protein decomposition takes place, and sensitization and then an impairment of the peripheral circulatory system is quite likely. In such sensitized persons spinal anesthesia may prove to be too much of a tax on the circulation, particularly if in the course of the operation more decomposition products of protein enter the circulation. The author gives his attention to the forms of collapse that develop a number of hours or even several days after the operation. This form of collapse is not the result of the spinal anesthesia as such, for the effect of the anesthesia has completely disappeared after a few hours. He emphasizes that this type of collapse is the result of auto-intoxication or of an allergic condition. An increase in the temperature after operation indicates that decomposition of protein is taking place. That a collapse does not result in all cases the author ascribes to the fact that the sensitivity for parenteral protein digestion varies in the different patients; it is determined not only by the patient's constitution but also by the preoperative condition. The author shows that gynecologic operations more than most other interventions, involve the decomposition of enormous quantities of protein (great vascularity of the region, bruising of tissues with large clamps, ligation of stumps and so on), which enter the circulation

To be sure, he admits that other forms of anesthesia will probably not reduce the danger of a peripheral circulatory shock, but he thinks that the incidence and mortality of this type of shock might be reduced if there were a method for the early recognition of a latent tendency to collapse. He thinks that the preoperative determination of the amount of protein cleavage products in the blood, or the determination of the reaction capacity of the organism by means of the cantharidal blister, might be of value. He emphasizes that preoperative digitalization of the patients is without avail, for the prevention of central collapse does nothing to prevent peripheral collapse. He thinks, however, that the use of vascular tonics that favor a backflow to the heart will be of help. He warns against protein shock therapy in patients in whom a later operation is probable and he also advises that alkaloids and barbituric acid preparations should be used sparingly. It is essential that in the course of the operation bruising of tissue be avoided as much as possible.

Artificial Detachment of Placenta—Budimlic injected into fresh placentas through the umbilical vein solutions of various astringents and watched their action on the placenta. He obtained the best results with a 0.45 per cent solution of alum. He describes the method as he employs it to effect detachment of the placenta. In 1 liter of boiling distilled water he places 45 Gm of crude alum, lets the solution cool to 39 C and then injects at once 300 cc of this solution into the umbilical vein after it has been closed with a Péan clamp. If detachment of the placenta does not follow within fifteen minutes, which is rarely the case, an additional 50 or 80 cc of the solution is injected. As a rule it is possible to wait for an hour or even longer for the complete detachment of the placenta, because the uterine hemorrhage usually ceases following the injection. The author made the injection into the umbilical vein as a rule forty-five minutes after the delivery, but, in cases in which the hemorrhage threatened the mother's life, the injection was made immediately after the delivery. He employed the method successfully in nineteen cases, in eight of which manual detachment had been necessary in previous deliveries. He points out that if manual detachment becomes necessary in spite of the injection, the difference in the consistency of uterus and placenta (the placenta is harder as the result of the injection) facilitates the manipulation considerably. He emphasizes that the method is quite helpful for the practitioner, for all that is needed is a supply of 500 cc of alum solution, a syringe of 150 cc capacity and a Péan clamp. Because the solution is hypotonic, the injection is without danger and he considers it superior not only to the manual detachment but also to Crede's manipulation for the latter method may be followed by inversion of the uterus or by collapse.

Malignant Hypertension with Cerebral Complications A. M. Meerloo—p. 3868

Hypochromatic Anemia with Symptoms in Ocular Fundus—Daniels and Roelofs describe two cases of secondary hypochromatic anemia. Symptoms common to the two patients were inflammation of the optic papilla, temporary disturbances of voluntary movement, migraine and vomiting. The patients also showed marked changes in the fundus of the eyes resembling those found in brain tumor. The neurologic symptoms coincided with a symptomatic migraine and were considered the consequence of a spasm of the blood vessels caused by the anemia. The changes in the fundus of the eyes were explained as resulting from contractions of the retinal vessels owing to the direct influence of the anemia. The literature concerning similar cases is discussed and in many respects confirms the

hypothesis. The success of treatment of the anemia on the other symptoms supported the theory that the anemia alone was the primary cause.

Treatment of Parkinsonism—Wuite describes the technique of the Hirsau sanatorium treatment of parkinsonism as reported by Anna Kleemann. The patient is placed in a luke warm bath in the morning, during which time passive movements are made with the limbs. After the bath, the limbs are massaged and the patient rests. In the evening he is given 0.25 mg of atropine sulphate in 0.5 per cent solution. The second day the dose is doubled and the third day tripled. After the third day the dose is given every three hours, preferably at 6 a. m., 2 p. m. and 10 p. m. Dryness in the throat is no contraindication to an increase in dosage. If disturbances, such as vertigo, sensations of heat, palpitation of the heart and gastric complications, occur, the dosage remains the same until these symptoms disappear. The maximal dose varies according to the individual. When the limit of tolerance has been reached it is indicated by such symptoms as dulness, headache, apathy and sleeplessness. Physical treatment simultaneously administered consists in daily baths, massage, active and passive movements of the limbs and physical labor. The first symptoms to disappear during treatment are vegetative symptoms, such as excessive salivation, tear flow and secretion of sebum, along with disturbances of the muscular tonus, such as stiffness, slowness and defects of speech and ambulation. The last to disappear are the involuntary movements (tics and tremors) and the psychic disturbances (slowness, apathy, blocking of thought and depressive psychoses). According to the author the optimal atropine dosage should be determined by the disappearance of the symptoms of the motor sphere, particularly those of the muscular tonus. Treatment should be administered in an institution with all facilities at hand.

*Experiences with Treatment of Diabetes with Insulin-Epinephrine V. Clausen and M. C. Lottrup—p. 747

*Insulin-Epinephrine Treatment According to Clausen T. T. Andersen—p. 751

Tabetic Arthropathy of Column Two Cases C. Krebs—p. 752

Treatment of Diabetes with Insulin-Epinephrine—Clausen and Lottrup, who found that the addition to insulin of minimal amounts of epinephrine causes a protracted resorption of insulin injected subcutaneously without otherwise changing the effect of the insulin and without unpleasant by-effects, illustrate the advantages of the method in five of the twenty-five cases in which this treatment was used. The first two patients, whose blood sugar varied greatly with two injections of insulin daily and who were often at the point of hypoglycemia, improved on the use of insulin epinephrine 1:50,000 for both injections and still more when insulin epinephrine 1:25,000 was used for the evening injection. For such patients the authors give most of the carbohydrate from three to four hours after the morning injection and a moderately small amount with the evening meal. So far as is feasible an interval of twelve hours between injections is advised. The next two cases show that with insulin epinephrine it may in some instances be possible to change from two injections to one daily. As little carbohydrate as possible is then given with the evening meal. The fifth case shows that with insulin epinephrine good results may sometimes be attained in a few days.

Insulin-Epinephrine Treatment According to Clausen—Andersen says that of seventeen diabetic patients under ambulant treatment since January 1935, all given insulin epinephrine, four are unchanged and thirteen improved. In seven of the thirteen glycosuria has largely or wholly disappeared, nine patients, who before the treatment had hypoglycemic attacks, have since the start of this treatment been free from hypoglycemic symptoms. The only patient still presenting symptoms of hypoglycemia is suffering from epilepsy. The author considers Clausen's method advantageous and well worth using until slowly resorbable insulin is available, and possibly even then if the new insulin proves too expensive.

FUNCTIONAL NEUROSES AS COMPLICATIONS OF ORGANIC DISEASE

AN "OFFICE" TECHNIC OF APPROACH, WITH
SPECIAL REFERENCE TO THE NEURO-
DERMATOSES

JOHN H. STOKES, M.D.
PHILADELPHIA

For the past fifteen years a special interest in the functional neuroses and in behavior problems has led me to develop, from a variety of sources, a technic of "office" analysis and treatment of this now recognized element among the many causes of cutaneous disease. A sufficient number of patients have considered this feature of the management of their cases at my hands as an important element in their permanent recovery or satisfactory adjustment to encourage me to present the mode of approach for trial in cases in which circumstances do not permit or justify the calling of a neuropsychiatric consultation and special or sanatorium treatment. With apologies, under the pressure of condensation, a highly didactic form is used, without citation of case illustrations or discussion of percentage results.

DERMATOSES

The dermatoses to which the technic is applicable include neurodermitis in the broad sense and special forms of this disturbance, such as cervical erythema and acute exudative neurodermitis, flexural neurodermitis, prurigo of Besnier, the cutaneous phase of the eczema-asthma-hay fever complex and extensive lichen simplex chronicus, chronic urticaria, the rosacea complex, "neurogenous" pruritus, cutaneous infections showing a close relation to the sweat-vascular mechanism, such as "dyshidrotic" eruptions of the hands and feet, and the mycotic-pyogenic-allergic syndromes, such as the "levarids" and "eczematids" and the psoriasiform parakeratosis of Brocq. The principles outlined are applicable also to the neurogenous phase of asthma and to the neurogenous aspect of the allergic background in general and to dermatoses complicated by excoriative injury.

THE PERSONALITY TYPES INCLUDED

It is not intended that the method here presented shall apply to the pronounced grades of warping of the personality amounting to actual hysteria or the recognized psychoses, as an office procedure for patients with neurasthenic and psychasthenic collapse, for malingerers, or for patients with severe grades of conduct disorder demanding the use of the full psychoanalytic

procedure. This is essentially a plan of assisting the patient who is "up and around" to recognize and correct the functional nervous background of his dermatosis. The nervous states susceptible of benefit by this form of management are the so-called vagus-sympathetic imbalance, especially "vagotonia", neuro-circulatory instability of Becker, the "tension frame of mind" of my own writings, and the simpler personality disturbances, including elementary sex problems, exclusive of homosexuality and actual perversions, such as sadism or masochism, the commoner maladjustments of the personal life under the strain of domestic load and incompatibility, finance, relatives-in-law, employment and the like, and anxieties, simple phobias, fixations, repressions and exhaustion.

RECOGNITION OF THE NEUROGENOUS SUBSTRATE, ESTIMATION OF THE PERSONALITY

The following steps and earmarks are employed in recognizing the type of patient and of situation in which the subsequently described methods are applicable. Some experience with the etiologic analysis of urticaria and the rosacea complex has led to the belief that the type of personality rather than the adventitious circumstances is the essential factor underlying the cutaneous outbreak. The isolated circumstance merely pulls the trigger, so to speak. The discharge comes from the gun and its load. Hence, first, an estimation of the personality is necessary. This requires the taking of a routine history of the hereditary elements, not alone of insanity, neuroticism and breakdown, irritability and eccentricity, though these are essential but also of allergic trends, urticaria, the eczema-asthma-hay fever complex, vasomotor reactivity, migraine and hyperthyroidism, which are all closely related phenomena. An understanding of the personality background of the family and relations is at times a necessity. Occupation or occupational predisposition furnishes clues to the personality make-up, as for example in the trend toward excessive altruism seen in members of the medical, teaching ("a hereditary neurosis"—Plummer), nursing and social service professions, the identification of trouble bearers and responsibility hounds, the dray horses of their families and communities, and those engaged in or yearning toward highly competitive careers with marked "spotlight" leanings, such as literature, drama and public speaking (das liebe Ich). Achievement also requires early appraisal for its outlet value, the completeness with which it satisfies or the degree to which it has overrewarded or overstimulated the personality trend. Leaders, drivers, tyrants and hypereffectives in general explode into the cutaneous neurogenous field under stress, excess or frustration. Stability, reactivity and stamina must be estimated by the history of ability or inability of the whole personality and of the individual organic systems, such as the

From the Department of Dermatology and Syphilology University of Pennsylvania School of Medicine.
Read before the Section on Dermatology and Syphilology at the Eighty-Sixth Annual Session of the American Medical Association Atlantic City N. J. June 12, 1935.

gastro-intestinal tract, to perform continuously and effectively under load. The patient whose eyes give out, whose stomach fails him, who has an "American bowel" (mucous colitis) falls within this field quite as much as the chronic changer of occupation or the too persistent essayer of one goal. Becker insists that an inborn inadequacy akin to the probable basis of neuro-circulatory asthenia underlies the collapse of the neuro-vascular mechanism in the skin of many of these patients. They are the subjects of a perpetual disposition to exceed the speed which their chassis will permit without rattling to pieces. For the appraisal of these elements, two sessions may be required.

THE RECOGNITION OF TENSION

As far as the identification of something with a large intuitive element can be reduced to words, the estimation of the tension of the individual involves these elements. One must learn early to differentiate the open and the closed types (not necessarily extrovert and introvert), the former in a constant tremulous flutter, the latter seen from behind a mask, darkly—the "poker face" of American parlance. An early opportunity should be taken to appraise the neuromuscular state by carefully but unobtrusively observing the posture, movement and enunciation. Almost perfect imitations of relaxation in pose may be observed in the closed or repressed type, but the intent gaze and occasional betraying diaphragmatic sigh as an unconscious release may disclose the internal tension. The mobile or open type is easily recognized by the fidgets, constant movement and jerkiness of action and enunciation, but it may be necessary to have the less obvious type of patient lie on the examining table to observe the elevation of the chin, the thrown-back tendency and rigidity of the neck, the tense abdominal wall, the arched lumbar spine and the thrust-out feet. I have even had reason to suspect the unwillingness of a woman to lay both buttocks on the table as suggesting a sex substrate or repressive trend. The clipping enunciation and heightened tone of voice of the vagotonic type and the jerk that he gives to his shoes and shoestrings are evidences of the high output of central energy that is constantly bombarding his peripheral structure, so to speak. The facies is a material aid in estimating tensions. The veil of impassiveness of the closed type may be lifted by the eyes, which have an intentness, a dark reserve or a birdlike alertness combined with impenetrability. The open type of patient blinks, shies, suffuses, or simply looks about. Unwinking eyes may express an excessive internal pressure under excessive control, while "blinkers" have at least discharge, but not release of tension or relaxation. The eyebrows and forehead are of interest, the brows lifted toward the hairline mean anxious concern—either the situation has overwhelmed the patient or he fears that it will. This is a totally different state of tension from that of frowning preoccupation, in which the patient still feels himself in command of the problem. The behavior of the small muscles about the lips and chin is a very sensitive index of inward tension, and the twisting lip, the wry smile, the tremor, lip licking and biting and the tremulous or puckered chin under questioning should be closely watched.

I have thought that the characteristics of sleep or sleeplessness assisted materially in gaining insight into the nervous state. The late retiring hour of the person too tired to make the effort to undress, who simply goes on and on and on, the patient who lies awake after

going to bed, a victim of too much thought and too little exercise, the insomnia of the small hours, due to worry and characterized by the revolving wheel or cycle of recurring small problems or minor crises and vexations overlying either hunger or some great unrecognized lack or strain, the early rising of the sex hungry with its burst of morning walking or calisthenics. The respiration of patients should be watched not only for rate and depth but also for the characteristic instinctive release of diaphragmatic tension already mentioned—the full breath and sigh interpolated into a period of sitting inactivity. The reactions of patients in all these particulars should be watched during routine questioning as well as during the "cathartic" approach to be described. Often a verbal description of the sensation of being wound up at the back of the neck and of carrying the diaphragm high in the chest brings an instant confirmatory reply from the patient, who there upon, recognizing your comprehension of his state, proceeds to "open up." Finally, a sixth sense, gained by experience must be brought to bear on these patients, an instinct which, after about so long a period of failure to reach a result by attention to the ordinary medical considerations, tracks directly toward a sensed psychogenous factor and by an intuitive touch directs the shaft of a question straight at the heart of the matter.

APPRAISAL OF THE VASOMOTOR STATUS

The come and go of color, the flushing of the dermatologically involved area under observation and stress of waiting, questioning or examination, the bluing of the hands and feet in a dependent position or when the circulation is at all impeded, as on sitting over an edge (table, toilet seat or bathtub edge), the striking blanching of the flushed hand on elevation, the occurrence of acroparesthesias and the prickling of "going to sleep" when the arms are raised above the shoulder level in bed, "dead finger," the vasomotor blanching of one or more fingers without apparent cause, the flushing of the rosacea area are all useful indexes of the reduction of vasomotor tone, resilience and response that accompanies prolonged stress and seems at times to have a relation to the state of the intestinal tract, perhaps with respect to histamine or acetylcholine-forming flora. In this connection patients will often notice that their shoes or wrist watch straps have become tight even before the circulatory stasis becomes visible as a result of a change in color. Dermographism should always be tested but will vary from the pale stich to wheal formation without necessary correlation with a mental state. Vagotonic persons show preponderantly marked red dermographism, however.

THE SWEAT MECHANISM

Anomalies of sweating are not usually recognized as having specific application to the state of mind, though Brill¹ mentions the views of Schwenkenbecher and Spitta. I have, however, seen enough examples of palmar hyperhidrosis associated solely with the meeting of strangers, with sex neuroses and with office visits or school examinations to recognize the profusely sweating palm as a warning sign of a neurogenous substrate. To a lesser degree this applies to axillary, vulvar and scrotal sweating as well as to the sweating of the elbow flexure observed in neurodermitic patients under stress. The whole problem of flexural, palmar

¹ Brill, E. Die experimentellen und klinischen Grundlagen zum neuropathischen Typ des Ekzems. Arch. f. Dermat. u. Syph. 150: 580 1926.

and plantar sweating as a functional neurosis providing part of the background, together with vasomotor changes, for the cutaneous mycoses, surely deserves the most serious study

THE GASTRO-INTESTINAL SYMPTOMATOLOGY

In cases of neurocutaneous functional disease the symptoms tend to follow the hypochlorhydric rather than the hyperchlorhydric pattern. The physiologic decline, so to speak, of hydrochloric acid secretion in later years the nervous irritability associated with accumulated load and stress and the depressant effects of chronic worry and shock on the gastro-intestinal secretion all tend to make the patient with a cutaneous accompaniment of a functional neurosis the victim of (1) pain due to spasm, (2) spastic constipation often alternating with periods of diarrhea or fermentative reaction due to a relatively undefended intestinal tract (3) aerophagia with eructation of relatively nonacid material, (4) flatulence associated with a gas-producing flora of the Welch and *Bacillus mucosus* types, encouraged theoretically by a high intestinal p_H , (5) low blood pressure, flushing of the face depression and peripheral vasodilatation, as parts perhaps of a histamine and acetylcholine absorption syndrome and (6) a tendency to urticarial and other ingestion allergic manifestations from abnormal split product absorption secondary to the deficiency of hydrochloric acid and a tendency to chronic low grade gastro-enteritis. This semicharacteristic symptomatology should be elicited by much more detailed questioning than is usually employed, and a mere test meal is no substitute for such an inquiry. The correction of the underlying neurosis as well as of the physiologic changes is a necessity for lasting therapeutic results.

TREATMENT OF THE NEUROGENOUS FACTOR, RAPPORT

The establishing of a proper but not excessive or relaxed degree of intimacy with the patient is the first and a generally familiar essential to command of the psychoneurogenous situation. Contrary to a common impression, physical surroundings need not be—in fact should not be—too impressive. Intellectual and professional prestige is more useful, even the psychotherapy of warts was said to be more effective in Bloch's hands as professor than in those of physically more impressive associates. Age is only superficially important at the outset, but there can be no substitute for an extended and well digested life experience. Without it, it seems to me, psychiatric effort tends to be directed by the head without the heart, a skeleton science of mind without flesh of human nature. The degree with which the examiner shares himself and his own life experience with the patient varies from case to case and should not be overdone. Resort to the third person and the citation of parallel cases may give the necessary detachment, but at critical moments the confessor who is not too afflicted with the self-confessional impulse will know by instinct how to make the patient understand that his physician knows too, and not from books. De Schweinitz has very skilfully brought out this sharing aspect of the constructive act of helping a person out of trouble. I am satisfied that there are occasions when no degree of serene detachment takes the place of an ability to make the patient feel, even though by indirection that his guide has personal knowledge of the trouble he is seek-

ing to adjust. As physical surroundings for the examination, almost anything will be usable by the expert, and even the interruptions of an office staff serve a purpose in reminding all concerned that time flies and that the examiner is in demand. On the other hand, complete relaxation on the part of the examiner during the conversation is absolutely essential. His grasp of the situation vanishes the moment the patient senses that his new friend is in a hurry, troubled, preoccupied, tense, rushed or disturbed. Even the informal attitudes of the examiner, stretched out in his chair, hands in hair or draped over some convenient standing object, may open a whole path of investigation in some cases, while a little more form, but never pose, is useful in others. Finally, a sense on the part of the patient that he has been completely examined is essential. It is difficult as well as unwise to impress the claim of the mind until the body has had its due.

Stripped examination provides the often invaluable posture relation of the patient lying on the examining table, helpless and disrobed but covered, in imitation of the bedside tradition, while the physician in office regalia performs both his medical and his priestly function. Twilight, quiet and a fixation equipment of

Commoner Nervous Factors

	Urticaria 100 Cases	Rosacea 81 Cases	Controls Psoriasis 100 Cases
High tension (tension frame of mind)	41		13
Overwork excessive mental exertion being driven late hours	33	25	2

Shock	12	2	1
Financial worries bad business conditions	11	5	3
Emotional stress	8		
Marked repressions and inferiorities	3	4	1

sounds and lights are not called for in the technique I have employed. The estimation of the case and a certain matter-of-factness in the approach, devoid of mystical trappings, have seemed sometimes to be better secured in the purely technically equipped dermatologic examining and treatment room than in the carpeted, book and diploma lined office. Perhaps the surprise with which the patient finds his spiritual troubles being taken into account in the midst of desiccating machinery, x-ray tubes and lamps has a shock therapy value in breaking down his reserve. A good light too is necessary for an accurate appraisal of the mental as well as the physical status.

CATHARSIS AND THE CONFESSIONAL APPROACH

After the identification of a neuropsychogenous substrate has been accomplished in one or several inspections and interviews, an effort may be made to relieve the patient of his load. This does not necessarily call for a forced confessional or even for a directly answered question. An understanding glance of the eye and a hint may be quite enough to open the way for therapeutic suggestion. Getting the patient to talk, while tempting as an evidence of one's gift and flattering to one's ego, is often followed by a reaction against the whole situation and a sense of shame on the part of the patient, which ends one's usefulness in the case. Extended confession is a morbid desire in some patients

and a needless time consumer in others. Studies of the rosacea² and urticarial³ complexes have suggested a pattern of common factors as a guide to intuition in psychoneurogenous cases, which with the relative weights of the items is given in the accompanying table.

The direct question is often necessary and must be made matter of fact on sex matters, relatives-in-law, finance, defeat, antagonisms, conflicts and fears, among which last "marriageability," the threat or approach of old age and domination by another or by a situation (the Watsonian basic fear of being bound or helpless?) seem quite as common as fear of illness, incapacity or death. I have also found useful, as a species of outline both for questioning and for describing to the patient his own plight, the following insight leads along which the troubles that underlie cutaneous explosions seem to concentrate.

THE COMMON INSIGHT LEADS

What to Look for in the Patient's State of Mind

- 1 The sense of "must" or obligation, the unending stretch of things ahead that simply have to be done.
- 2 The impasse or "insoluble" problem, most often somebody who won't die.
- 3 The conflict of duty and desire. Often it is the family "midchannel."
- 4 The sense of absolute contradiction—the impossible has happened, water has run uphill, the dykes have failed, our trust is betrayed—the beginning of the buried complex and hysteria.
- 5 The last straw. "I stood it until that."
- 6 "Defeatism"—the mental attitude of "it can't be done," sometimes a combination of constipation and exhaustion.
- 7 Self pity.
- 8 The "might have been." The backward looker.
- 9 The sense of futility and uselessness, of being no longer needed, of being set aside, superseded, passe, especially important in persons over 50, mothers of families with grown children, men who have "retired" without cultural resource.
- 10 The reaction to domination. This is the "electric relation" between the prurigo or diathetic eczema personality and the antagonistic parent, teacher or relative.
- 11 Fear, fixation (the blaming of the body for a mental pain), inferiority, repression and defense. These are the psychiatric *grenzgebiete*.

By direct question, by skilful inference, but always with a certain shrewdness, one may with these guides feel oneself into the depths of a personality with a surprising degree of success. It is important not to make too many misses, a tendency to which is the commonest result of hurry or pressure and of failure to consider the history and personality "front" of the patient carefully in its entirety before attempting to open the door.

REASSURANCE AND READJUSTMENT

Having formed by the foregoing methods a picture of the patient's problems and of his spontaneous reaction to them, one is wise first of all to resist the desire to give direct personal advice or to enter into a discussion of specific courses of action, especially those that are past. The position of detachment, which is after all the controlling one here and which it is wished the patient himself should attain, is not favored by a rostrum delivery of advice. To overcome this tendency, to broaden the base and to impersonalize the

myopic egocentricity of the patient's outlook, I have found it worth while to present to him, perhaps better to remind him, somewhat in the manner of the Greek chorus chanting the flow of life from the wings, of some further general principles which he can use in relieving the tension and conflict within him. Not necessarily in the order of their exposition in the particular case, the patient is to be told or reminded

1 Of the assurance of recovery, optimistically but not unqualifiedly presented.

2 Of the remarkable self-righting power of the mind and of the mechanism of mental recovery by bringing the problem to the surface and naming it, frankly and straightforwardly. Several sessions may be needed to teach him this "fishing and labeling" process.

3 Of his right to a legitimate self confidence and self esteem. "Never blame unless you also praise."

4 Of the influence of the "stream of consciousness," the self conducted mental commentary that, for good or ill, gathers our rills of thought into the river of personality. "What you call a thing it is—what you let your mind say about it, you do."

5 Of the resolving power of time. No lesson is harder to learn, but none more salutary than that all things, and above all peace, come to those who know how to wait.

6 Of getting around what one cannot get through or over, some suggestions for a technique of evasion or sidestepping.

7 Of the serenity of the mature. "Not as good, or as evil, but as life." Hyperreaction is childish.

8 Of the value of detachment and the power of noninterference—especially important to impress on the overzealous parent confronted by the rebellious child.

9 That "It won't last—nothing does"—an impression of the mutability and transience even of the worst.

10 Of the vice of continuous effort even in a good cause and the exhaustion that comes to the perpetual striver who never grants a moratorium to himself or others or indulges in purposeful uselessness, masterly inactivity or conscientious laziness.

11 That he is not alone—a need of human beings voiced in the range of expressions from "Misery loves company" and the "Somebody cares" of the relief campaigns to the unforgettable. Not a sparrow falleth.

12 Of the relief of large thoughts—a looking out over the universe a hilltop perspective. In this form of impersonalization a planetarium, a volume of popular astronomy and an opera glass may be life saving.

13 What to do about solitude, isolation and companionship.

14 What to do about a change of scene.

15 What to do about drugs.

16 What to do about rest.

It must be evident that a purely homiletic delivery of these parcels of worldly wisdom and spiritual admonition may deservedly fall flat. None the less, it is remarkable how a sorely pressed and battered individual rallies at the sound of some seemingly commonplace slogan uttered by his physician or moves forward behind some more stirring, white-plumed symbolic thought. One is often astonished at the regained self possession, lessened pruritus and decreased vasomotor irritability that follow a single session based on stereotyped patterns such as these. The problems involved in solitude and isolation, companionship and change of scene are contrary to common conception, highly individual. In general, solitude builds the stronger and sounder recoveries but is the harder medicine to take. Change of scene is invoked too much in a routine way but is life saving for major troubles in strong personalities. I am a determined opponent, within my field of observation, of the too ready resort to sedative drugs, except atropine and calcium. The problem of rest is so important as to absorb the remainder of this paper.

A TECHNIC FOR REST THE SIX-POINT ATTACK

It is understood that this paper is concerned with those who must keep going, it describes an office, not a sanatorium, approach, though perhaps applicable in "rest house" conditions too. As I present it to the patient, the method revolves about six principles as follows:

1 A temporary repudiation of responsibility and a defense against overload obtained by one or all of four methods:

(a) The adopting of a DGAD (don't-give-a-damn) attitude. To those who find this way of phrasing it unpalatable, other angles or alternatives may be offered, ranging from "Let the other fellow do the worrying," and the conscious shifting of the burden of the seemingly unadjustable on to the shoulders of the Infinite, as in the "Divine Mind" of certain religious groups. The release of some forms of prayer may be a proper variant on this mode of tension reduction, the upper end of the spectrum of *Fiat lux*, so to speak.

(b) The sloganization of the casual and the ephemeral as opposed to the enduring and purposeful, a temporary fatalism expressed in the phrase "A hundred years, ten years from now, what will this matter?"

(c) An attack on the procession of "musts" by an outright resigning from blocks of obligations and the temporary repudiation of others. Only the completely egocentric person suffers from the delusion that his world cannot go on without him.

(d) An attack on "destinationism," the worship of the goal and disregard of the method, the excess purposefulness, usually competitive and designed to beat the other fellow, which marks the pillar and victim of our American type of civilization. This is the distinctive inability to play for the sake of the game instead of the victory that mars our sport and makes our virulently score-counting golfer quite as much as our business man an object of pity rather than respect.

2 A discipline in objective self analysis by the deliberate division of the personality into overmind and undermind. This is sloganized as the "Big and Little Mary" device, in which the wiser oversoul talks soothingly and illuminatingly to Little Mary, the perverse and mischievous sprite whose rebellious leavings and gyrations keep the personality in a state of turmoil.

3 A reeducation in impersonal detachment by an attack on *das liebe Ich*, the "Beloved I" of the competitive egocentric striving, achieving personality, which cannot bear defeat or brook second place. The sense of the personal unjustness of life and fate is an often unrecognized phase of this personality trend.

4 A technic of neuromuscular tension detection and release. Even so-called rest in bed may fail to provide it unless special instruction is given.

5 A technic of neuromuscular tension discharge. This is the objective of occupational therapy broadly conceived.

6 Invocation of the sense of the ridiculous. Like love and hate, anger and laughter are the obverse and reverse of the same discharge pattern, so to speak. The conception is valuable in detoxifying chronic or recurring as well as acute exasperations. It acts, as has been said, through the sense of the ludicrous which even a hard-pressed personality is slow to lose. "Smile, damn you smile."

The aggregate effect of bringing several of these conceptions to bear on the patient's problem is to put a disturbed personality to rest, and I believe that valuable though physical or bed rest when ordered may be its usefulness is often defeated by insufficient attention to the detail of mental and nervous rest. My earlier experience with hospitalization and the later need for producing the same results under ambulatory and office conditions in patients who positively could not without financial and personal disaster seek their beds or submit to a full neuropsychiatric procedure have convinced me not only of the very fair proportion of effectiveness but also of the positive advantages of this approach in the dermatoneuroses. The patient recovers

by a positive process of adjustment to his environment rather than by isolation and segregation from it. It is, of course, granted that there are patients who cannot recover in their usual environment, but they are fewer than is generally conceived. The patient managed by this technic is, moreover, armed in a positive way by reeducation for the future, rather than merely tided over the present situation by his rest.

It may be argued that there is a positively unmoral quality to the fatalism and repudiation, the outright enjoyment of irresponsibility to be taught the patient under caption 1. Patients will usually make this objection to the view advocated. They may be assured of the harmlessness of the procedure for their type, which is so constructed at birth that it can never adopt hedonism as a lifelong philosophy. They will return to their responsibilities all too soon and all too personally, for their egocentricity will propel them willy-nilly. They should be told of the analogy of muscular fatigue and the delayed recovery after once passing the fatigue limit, and impressed with the four thousand year old words of the Ancient Wisdom attributed to Ptah Hotep, whose couplets should be on the desk of every neurodermotic subject:

The archer striketh the target,
Partly by pulling, partly by letting go,
The boatman reacheth the landing,
Partly by pulling, partly by letting go.

It is a test of nonreception by the patient and his need to profit by this point of view, when, after its presentation he replies eagerly "Doctor, I'll try to do what you say!" He is at once reproved for again bringing effort to bear on what can and should be done only by a shrug, a gesture of dismissal. The rapidity and extent of the relief of mental tension afforded by the question "A hundred years from now" is a constant surprise. It is grasped like a straw by a drowning man, and often nothing more than a little training in the Jacobson technic of relaxation is necessary to start recovery. The attack on the procession of "musts" can well begin with the order to stay in bed for breakfast and to have the telephone answered by some one who will say in almost joyous accents "The doctor says Mrs. X is ill and must not be disturbed. She regrets that she must present her resignation, under his orders from your committee." This invocation of the sickness defense, perhaps dangerous when self adopted, is quite harmless under supervision, in my experience. The cancellation of the business lunch, a device of the devil in the American technic of living, reading at the table instead of correcting the children or being agreeable and the noonday break and rest on a couch while the telephone is plugged are useful details that are much more practical than the taking of long vacations away from home. The mere description of destinationism usually suffices to induce the patient to try the casual and episodic as a relief. He can appreciate the reminder of his bent-pin fishing days when a subsistence catch or less was enough, and the surroundings, not the fish alone, made the fishing memorable. Stopping all forms of score counting is literally the first step in this readjustment and often requires the withholding of daily papers, business reports and visits from partners, wives and husbands. The discipline in objective self analysis sounds like child's play, but it is not. Its systematic practice leads to a remarkable recovery of balance and perspective. The turbulent, weak and unstable elements in anything approaching a normal personality, secrete-

gated in this way, slowly become controllable rather than merely stamped on and suppressed. This is decidedly preferable to the false front of the "poker face," hiding a scratching, kicking child beneath her apron, so to speak. It disarms Little Mary to view her sympathetically but with detachment as a brat common to all of us. To the charge of egocentricity most human beings react instantly with a defense, followed by retreat and readjustment, so that it is comparatively easy to get the patient to see the point in caption 3. This is notably an element in the prurigo-asthma-hay fever personality in which intense egocentricity appears now in competition for marks in school, now in violent antagonism to a particular teacher, now in conflict with a "don'ting" parent and again in an impenetrable *chevaux de frise* of negativism and inaccessibility. The guidance of these patients into outlets in which their best finds expression with comparative smoothness of flow, instead of a perpetual clatter over stones, is a task for the behavior specialist and the mental hygienist.

A distinction is drawn between neuromuscular tension release and neuromuscular discharge by muscular work. It is explained to the patient that all thought translates itself instinctively into one or another form of muscular effort which, if it does not result in gross movement, at least puts muscles under tension, exhausts energy, heightens irritability and makes constant demands on the nervous, endocrine and vasomotor systems. A reversible relation exists in the equation representing this process ("no affect without effect"), so that it is possible to reduce the activity of the mind, calm it, rest it, by learning to recognize the tension of groups of muscles and by issuing to them an order to relax. To train himself in letting go, the patient must, as Jacobson⁴ has so beautifully pointed out, learn to detect the feel of tension in his back, his neck, his arms, his diaphragm, his fingers and feet, his very supra-orbital and ocular muscles. In the technic that I describe to the patient, he begins on retiring. As he lies with his eyes closed, he makes the round of his musculature, like Diogenes with his lantern, looking for a tight member. When found, the muscle group is ordered to let go. In a surprising way, when it is part of the general reassurance and adjustment process that I have described, patients learn to transfer the ability to detect tension and to give the order to relax, to the conditions of their working and, what is more important, their worrying day. In the midst of pre-occupation they can thus introduce periods of invisible rest, calming the mind, reducing the stream of motor impulse and the needless friction of conflict to a minimum. By a process of reversal, the ordering of the discharge pattern of a laugh to replace the contorted visage and tense muscles of rage unblasts the lightning, so to speak, and, though the laugh may in its incipience be a risus sardonicus, practice in time makes it a genial saver of the day.

As I have observed it, tension release is not usually sufficient. A technic of motor discharge devoid of the defects incident on the competitive, the destinational and the obligatory must be taught. To secure this essential point of view toward the matter, the patient is told to make craftsmanship, the well doing of some work for its own sake, his motive, rather than success involving comparisons. Thus, in a way, an artist loses

caste in this field if he exhibits or tries to sell, the poet if he seeks publication, the woodcarver if he calls in all his friends to sit or see. Excess routinization and mechanical performance of the selected work must be difficult or impossible, hence the worthlessness of mechanically performed housework and dishwashing as relief or discharge. Use of the small muscles of the hand and the eye in movements of precision gives the patient his sense of personal achievement. Of all commonly available devices the cross-country walk, the swim and the handicraft (which includes household tinkering) seem most available and serviceable. The essential in these discharge devices is, as I have said, a lack of specific time of completion, of destination and of stereotyped method. They must have a wandering casual quality, enjoyment for the present without thought of the past or future, without scheduled arrival, departure or route. The eyes, mental if not physical, must be on distant, impersonal gods, clouds, trees, the contest with and adaptation to the primitive—water, sun, wind, the earth. I have had diathetic persons repeatedly tell me that they have recovered while strolling in this way over hills that must have been green with the very plants to which they were cutaneously sensitive. Thus lowering of the threshold of nervous, perhaps sympathetic, irritability is a now recognized aid in the treatment of allergic processes, including asthma, and can very properly be applied to the treatment of the skin. We are all, and our patients too, familiar in theory with its virtues. The neurodermitic often only need to be reminded, albeit repeatedly, of its worth to them.

The use of the sense of humor or, better, of the ludicrous is more widely applicable than one is apt to believe as one views the dour or despairing countenance of the scratcher before him. The habit of taking himself seriously, the mistake of expecting personal justice and recognition in a world only a minute sector of whose horizon he is capable of perceiving, to say nothing of interpreting, accentuates, acutely or chronically, the vexation and irritability that underlies the cutaneous neuroses. By a flick as of an electric switch many patients can be brought to see the joke of it all, the scurvy joke, to be sure, but none the less the ludicrousness of expecting the universe to tune in on them and their miseries. Once convinced that, as with Will of the Mill, the stars do not jiggle at his shout, he settles down to something outside himself as more interesting and laughs off his itch. This is, in all seriousness, an important step in the recovery from and the prevention of secondary lichenification in the urticarial and neurodermitic subject. If, when the patient feels the peculiar pinging itch of which he complains, he can be induced to shrug and laugh and say "Hello, old boy, back again, sorry, too busy," and turn away amused, instead of digging in in rage and fear, half the battle is won.

CONCLUSION

The concluding paragraph of this presentation should be one of caution. This has been a description of a method for dealing with one factor, under everyday conditions, in the clinical background of the neurodermatoses. It is not offered as a substitute for a proper testing for allergic excitants, for focal infection studies, for the icterus index or for the numerous other avenues of approach to the multiple causal background in each case. It simply presents a technic of neuropsychiatric reeducation in the environment, usable by

⁴ Jacobson Edmund. *Progressive Relaxation. A Physiological and Clinical Investigation of Muscular States and Their Significance in Psychology and Medical Practice.* Chicago: University of Chicago Press 1929.

the humanely interested and reasonably experienced physician in his office. Of its worth in displacing phenol, menthol, the barbituric acid derivatives and expensive and unattainable rest prescriptions from dermatologic practice, I can personally testify

3800 Chestnut Street

ABSTRACT OF DISCUSSION

DR. EARL D. BOND, Philadelphia. I am glad that dermatologists do not think that they have to take over psychiatric terms in dealing with the practical emotional problems that occur in practice. Dr. Stokes has used his own original, practical methods, but he has worked on correct psychiatric principles. It has been recognized that the mental factors in most diseases are best handled by the doctor who gets there first; he has a chance to turn back the nervous symptoms when they are forming. With the right word or the right attitude he can discourage unwholesome emotional expression. The psychiatrist, keeping on his intensive treatment of difficult cases in his own field, can get ideas and learn lessons from his patients which he can pass on to practitioners in other fields. The dermatologist must often be the second doctor, the case being passed on to him by the family physician. For that very reason he must lose some chances for early recognition and the easiest treatment of mental and other factors, but he can much more easily than the psychiatrist, who must at the very best be the third consultant in the case, open wide the consideration of the patient's whole personality. The thing that psychiatrists have learned to do lately (and it has helped them more than anything else) is to listen. I often hear patients tell me "The other doctor just as soon as I opened my mouth to tell him how I felt put a tongue depressor in it." When advice and reassurance are needed Dr. Stokes gives six points which are effective and which are also general. This is supportive treatment. It doesn't take the place of the other pharmacologic and dietetic treatments. He avoids the danger of giving definite advice, of entering too much into the specific mental problem that the patient has. He leaves the patient to work out much of his own salvation. It is good for physicians to be told often how much "the skin is a loudspeaker of the soul."

DR. S. WILLIAMS BECKER, Chicago. The author's method of approach is ideal and will produce a high percentage of favorable results in skilled hands, but, like the teaching to patients of Jacobson's progressive relaxation, may not be efficiently utilized by the average physician. I have evolved a method of approach by the average practitioner the simplicity and applicability of which make it the most valuable part of the therapeutic armamentarium. I wish to emphasize the author's insistence on the avoidance of all semblance of hurry, since it is obviously difficult for a rushing physician to convince a patient that she must slow down, and this type of therapy requires longer sessions than are necessary in other instances. With the patient draped on the examining table, the physician fortified by physical observations, quietly informs the patient that she has a common, harmless condition that is rather easy to remedy, provided her cooperation can be obtained. The physician thus capitalizes on the marked suggestibility of these patients. She is told that the simplest, most easily understood explanation is that the dermatosis represents perverted fatigue. Instead of her feeling tired, her skin has broken out. Treatment will be followed by an appreciation of a feeling of fatigue and the dermatosis will improve. Therapy is directed first toward predisposing factors, such as overwork and disagreeable surroundings, and secondarily toward relief of the underlying exhaustion, by daily naps, daily sunshine exposure and temporary sedation by phenobarbital which I consider indispensable in children and temporarily advisable in adults. I have obtained almost unbelievable improvement by hospitalization and sedation similar to that used in treating the psychoses. The patient must learn the virtue of patience, tolerance and selflessness. Attention must be directed toward the sensory portion of the high-powered brain by telling the patient that she is the victim of exaggerated impulses, especially initial impulses which exert greater power over her than the precipitating causes warrant. While certain parts of this simplified procedure may require special ability, insistence on a daily nap and daily sunshine

exposure, along with temporary sedation by phenobarbital, can be prescribed by any physician and literally save the patient from herself.

DR. ELMORE B. TAUBER, Cincinnati. There is one thought that should be brought out here that is very pertinent and germane in these times of laboratory stress. This is a return, to clinical medicine, and Dr. Stokes has laid a splendid foundation to the pioneer back-trail to the art of medicine.

DR. JOHN H. STOKES, Philadelphia. It is a pleasure to hear Dr. Becker's simplification of the technic. In Chicago probably they don't have the desperations that they have in Philadelphia. My situation has been unfortunate in that I have had to deal with desperate men and desperate women who could not possibly take a daily sun bath or allow any time for a lamp treatment, or at least by no amount of mere argument could be led to believe that they could. That being the situation, I was forced to do it all in my office and this is the result of fifteen years of it.

FAT EMBOLISM

CANADIAN CHAIRMAN'S ADDRESS

R. I. HARRIS, F.R.C.S. (C)
Associate Surgeon, Toronto General Hospital
TORONTO

Fat embolism is one of the tragedies that haunt the efforts of the orthopedic surgeon. True, it occurs but rarely, but the dramatic suddenness of its onset and the fatality of its outcome create a profound impression.

Fat embolism occurs when fluid fat occludes the capillaries of important organs. The fat may come from any of the fat depots of the body, but for mechanical reasons, which will be discussed later, the fat contained in bone marrow is the commonest source. Normally, fat is stored in the form of globules, fluid at body temperature, within the cell envelopes of fat cells. Before fat embolism can occur, this fat must be set free by rupture of the cell membranes. Accidental or operative trauma is the usual agent that ruptures the cell membranes and sets free a quantity of fluid fat. Since bone marrow is the common source of the fat that gives rise to fat embolism, fractures and, to a less extent, orthopedic operations on bones are the usual antecedents of fat embolism. Though it is a rare complication of orthopedic operations, it probably is more frequent than is realized, since it is not readily recognized. This fact, in addition to its serious nature, justifies consideration of it on this occasion.

MECHANISM WHEREBY FAT EMBOLISM ARISES

It seems curious that such a normal constituent of the body as fat can give rise to fatal embolism. Some consideration of the complex mechanism whereby it occurs is essential to a clear understanding of the lesion. In lipemia, fat may be present in the blood stream in large amounts without embolism occurring. Lipemic fat, however, is finely emulsified and the finely divided particles easily pass through the capillaries. In fat embolism the fat is present in globules sufficiently large to fill the capillaries completely. Once this has occurred, the viscosity of the fat may be so great as to prevent the blood pressure behind from driving it through the capillaries. It is evident that fat embolism can occur only when fluid fat is set free in considerable amounts and under circumstances that will permit its easy entrance into the blood stream.

The cell membranes of fat cells are easily ruptured. Any trauma that involves adipose tissue results in the

Read before the Section on Orthopedic Surgery at the Eighty-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., June 13, 1935.

freeing of considerable quantities of fat, which at body temperature is quite fluid. The briefest observation will reveal how surprising is the amount of fluid fat that may be set free during an operation. From such a simple procedure as removal of a bone graft from the tibia there may accumulate as much as an ounce of fluid fat. When bones are injured, therefore, there is no lack of free fat for the potential production of emboli.

The mechanism whereby this free fat enters the blood stream is less evident. Though veins may be cut across or torn by operations or trauma, which at the same time free fat from its cell envelop, it is unusual for fat to enter the venous system. The sectioned veins collapse and the pressure of venous blood causes slow outpouring from the veins until such time as spontaneous clotting occurs. Fat can enter the venous system only under circumstances that will prevent the open ends of the veins from collapsing and permit the fluid fat to accumulate at a pressure greater than venous pressure. Three things are necessary before fat embolism can occur: (1) free, fluid fat, (2) accumulated under a tension that is greater than venous pressure and (3) open veins, the open ends of which do not collapse. Only under very special circumstances, fortunately, may one expect to see fat embolism.

Injuries to bones provide exactly the factors necessary for the production of fat embolism. There is abundance of fat in the bone marrow, readily set free by trauma or operation. The veins are held open by their attachment to the bony Haversian canals in which they run. It is not difficult for the wound exudate to accumulate under considerable tension. In operations on soft tissue the reverse is the case. Though there is abundance of adipose tissue and though much fat may be freed, entrance into the venous system is prevented by collapse of the veins. Wound exudate is less likely to accumulate under tension, more often it seeps out along the line of suture. There is less opportunity for the application of firm dressings than in operations on the extremities and hence less sealing of the exudate within the wound. Hence fractures and orthopedic operations constitute the most frequent antecedents of fat embolism.

PATHOLOGY OF FAT EMBOLISM

Once the fluid fat has been forced into the venous system, it is carried by the blood stream to the capillaries of the lung. The extent of the pulmonary embolism that thus arises is dependent on the amount of fat which enters the blood stream and the length of time during which entry is occurring. A large amount of fat forced rapidly into the venous system will produce the maximum effect, while a small amount, especially if forced in slowly, may cause no symptoms whatever. Extensive pulmonary embolism with fat gives rise to a definite clinical picture, the outcome of which is often fatal. Obstruction of the pulmonary capillaries interferes with oxygenation of the blood, hence cyanosis is a prominent symptom. The peripheral blood pressure falls from failure of an adequate amount of blood to reach the left side of the heart. Damming back of the pulmonary circulation results in great dilatation and ultimate failure of the right side of the heart.

If the right side of the heart is sufficiently powerful it may force some of the fat emboli through the pulmonary capillaries into the peripheral circulation. There it again comes to rest in the capillaries of any part of the body. The resultant symptoms are dependent on the nature and importance of the organ involved. Cere-

bral embolism is the most common, most important and most serious manifestation. This occurs, naturally, at a time subsequent to the pulmonary manifestations and it also is often fatal. The cerebral lesions that result are focal areas of necrosis, centered on the occluded artery and surrounded by a zone of hemorrhagic exudate.

Though the cerebral lesions are the most important of the peripheral manifestations, emboli may occur in any organ. Of the fat emboli that reach the kidney, a considerable quantity are excreted in the urine. This is of importance, since it constitutes one of the few exact means by which the condition can be recognized.

CLINICAL MANIFESTATIONS

From a consideration of the pathology of fat embolism it is evident that the lesion will manifest itself clinically in two principal ways, corresponding to the involvement of lung and of brain. Though many other organs than these may be involved, the conspicuous symptoms are related to the pulmonary and to the cerebral lesions.

Pulmonary Form—Symptoms of pulmonary fat embolism appear shortly after the fracture or operation. They may be so severe as to cause death in a few hours, or so mild as not to be recognized. It is obvious that the severity of the symptoms will depend on the amount of fat that has occluded the pulmonary capillaries. Within a few hours the patient becomes cyanosed, complains of a sense of constriction about the chest and suffers air hunger. The pulse becomes rapid, feeble and irregular. The blood pressure falls. Death occurs from cardiac and respiratory failure. As Warthin¹ pointed out in his classic monograph, the distended capillaries may rupture and pour into the alveoli some of their contained fat. The sputum then contains free fat globules and fat-containing alveolar endothelial cells.

Cerebral Form—This appears later than the pulmonary form, usually after the lapse of two or more days from the accident. In this interval the patient is free from any cerebral symptoms. Then follow restlessness, delirium, drowsiness and coma. Death may follow but recovery may take place. As this is a manifestation of systemic fat embolism, the evidences of involvement of other organs may be present. Most important of these, from the point of view of diagnosis, is the presence of fat in the urine as the result of kidney involvement.

DIAGNOSIS

The diagnosis of fat embolism is not easy. Since most cases occur in patients who have suffered severe injuries or have undergone extensive operation, it is not unnatural to regard their symptoms as due to cerebral concussion or shock. Even at postmortem recognition may be difficult, since the emboli are dissolved by the ordinary preparation of specimens in graded alcohols. Fat emboli can be demonstrated only by fat stains on frozen sections. It is altogether likely that mild degrees of fat embolism are common. An appreciation of this will be the most important aid to diagnosis. The knowledge that fractures and orthopedic operations are frequently followed by fat embolism will lead one to regard any pulmonary, cardiac or cerebral symptoms that may supervene as possible evidences of the condition. Definite and certain tests to determine the presence of fat embolism are lacking.

¹ Warthin, A. S. Traumatic Lipemia and Fatty Embolism. Internat. Clin. 4: 171, 1913.

Warthin, who first noticed the fat in the sputum, was inclined to think it was present in every case, but many writers have not been able to confirm this. The presence of free fat in the urine, when it occurs, is an extremely valuable aid to diagnosis. It cannot occur, of course, until systemic invasion has occurred, and sometimes is not then present. To date the diagnosis of most of the cases is based on postmortem evidence. With increasing recognition of the importance of fat embolism, more cases are being diagnosed on the basis of clinical symptoms.

FAT EMBOLISM COMPLICATING ORTHOPEDIC SURGERY

The occurrence of fat embolism as a complication of orthopedic operations is a matter worthy of serious consideration. Many fatal cases, proved by postmortem, have been reported in the literature. It is more than probable that many fatal cases have occurred without the true diagnosis being made and that recovery has occurred in innumerable milder cases without the suspicion of fat embolism. As Bissell² observes the falling arterial pressure and rising venous pressure of fat embolism closely resemble postoperative shock, and not unnaturally the death of a patient within a day or two of operation with a rapid feeble pulse is usually attributed to shock. The usual methods of examining tissues removed at postmortem fail to reveal fat embolism. Frozen sections and fat stains are necessary. Hence many cases almost certainly are missed. An interest in the problem frequently reveals a series of cases that otherwise would not have been recognized.

My own interest in fat embolism commenced with the loss of a patient following an operation for arthrodesis of a tuberculous hip.

A. G., a French-Canadian boy, aged 17 years was admitted to Weston Sanitarium June 27, 1934, for the treatment of tuberculosis of the hip. The history was characteristic and the physical and roentgen examinations gave equally characteristic results. November 22 an operation for arthrodesis of the hip was performed. This involved exposure of the hip through a Smith-Peterson incision, the removal of carious bone and the placement of a large graft across the line of the joint from the acetabulum to the neck of the femur. The operation was expeditiously performed and did not give rise to shock. A transfusion of 500 cc. of blood followed the operation as a routine measure. Two hours after the operation the boy was in good condition except for a rapid pulse. Six hours after the operation he became cyanosed and complained of a sense of constriction about the chest. The cyanosis steadily increased, the pulse became rapid and feeble, and the temperature rose to 103. He died twenty hours after operation. Postmortem examination revealed extensive fat embolism of the lung and slight fatty infiltration of the heart muscle.

I am indebted to Dr. K. G. McKenzie for the opportunity of reporting the following case.

H. L., a man aged 35, sustained a fracture of the tibia April 2, 1935. There was no head injury and he was not unconscious. The fracture was treated by open reduction and plating on April 3. He remained conscious and perfectly clear mentally until April 5. April 6 he became restless and would not respond to questions or cooperate in examination. Though he had had no sedative, he could be roused only with difficulty. He would not talk. There was no paralysis. Lumbar puncture revealed a clear fluid under increased pressure (17 cm.). The pupils were equal and small. There was early choking of the disks. On this day he commenced to cough up some frothy, bloody sputum. The temperature was 102 F and the pulse 120. The succeeding day he remained stuporous with intervals of restlessness. He remained restless and irrational until April 12 and then slowly improved. By April 19 he had apparently

recovered completely from the cerebral lesion. The urine collected on April 7 contained fat. The sputum was not examined for fat. April 16 he developed a patch of pleurisy on the right side, which cleared up in two days, and on April 23 a similar transient pleurisy occurred on the left side.

This is a clear example of cerebral fat embolism with recovery. The history of fracture and operation, the late appearance of cerebral symptoms and the presence of fat in the urine are all characteristic features. The late pleurisy probably represents the cyclic embolism of the lung described by Warthin.

The following two cases are included as probable examples of fat embolism, though definite evidence is lacking.

A boy, aged 10 years, was operated on for the removal of sequestra from osteomyelitis of the tibia. Toward the end of a rather long operation his respiration became embarrassed, cyanosis supervened and he stopped breathing. After an interval of artificial respiration, respiration recommenced but was irregular. Finally death occurred in half an hour. Postmortem examination failed to reveal any clear reason for death. Fat embolism was not suspected and was not specifically sought.

A man, aged 40, was operated on for the purpose of fusing a tuberculous hip. As the operation was being completed his respiration became embarrassed. In spite of artificial respiration he died on the table. Postmortem examination did not reveal any clear cause of death. Fat embolism was not suspected and not sought for.

These two cases resemble closely the proved cases quoted by Timmer³ in which death followed operation and postmortem examination revealed fat embolism of the lung and the brain. They are unusual in the rapidity of onset and the severity of the symptoms and the early death. They suggest that sudden death during operations may sometimes be caused by fat embolism.

TREATMENT OF FAT EMBOLISM

Unfortunately there is no adequate treatment of fat embolism. Much can be done to prevent it by the careful handling of fractures. The more the site of fracture is traumatized by unnecessary handling, the greater will be the amount of fat set free and the greater will be the tendency to drive it into the venous system. It may well be that fat embolism following orthopedic operations might be prevented by draining the wound for twenty-four hours. This would permit any free fat to drain away and would prevent the accumulation of wound secretions under the tension necessary to drive them into the veins. Ryerson's suggestion that a tourniquet will prevent the occurrence of fat embolism is probably a valuable one. Certainly while the tourniquet is on no embolism can occur and during this interval the opened veins have an opportunity to develop occluding thrombi.

Once established, fat embolism can be treated only by symptomatic measures. Venesection to relieve the distended right heart is probably of value. The administration of saline solution intravenously may facilitate the passage through capillaries and aid in freeing some of them of their fatty emboli. An oxygen tent should be used for the treatment of cyanosis.

CONCLUSIONS

1. Fat embolism is a serious complication of injuries to and operations on bone.
2. Its occurrence is probably more common than is realized, since the symptoms may easily be mistaken

³ Timmer, H. Epileptiform Convulsions and Fat Embolism After Nonsurgical Orthopedic Intervention. Nederl. tijdschr. v. geneesk. 2: 173 (July 19) 1919. abstr. J. A. M. A. 73: 1403 (Nov. 11) 1919.

for shock and the lesion will not be found post mortem unless special methods of examination are used

3 Clinically it manifests itself in a pulmonary and a cerebral form

4 The occurrence of fat in the sputum and in the urine are valuable diagnostic signs

5 The possibility that pulmonary embolism may complicate orthopedic operations should be borne in mind and such preventive measures taken as seem valuable. A tourniquet should be used in operations on the extremities. Drainage of wounds of bone for twenty-four hours probably would prevent at least some cases of fat embolism

THE PEDIATRIC VIEW OF OTOLARYNGOLOGY

EDWARD CLAY MITCHELL M.D.
MEMPHIS, TENN.

The pediatrician has been defined as a general practitioner who limits his field of practice within the boundaries of the ages of childhood

Pediatrics has been defined as that branch of medicine which has as its purpose the making of a better next generation. Infancy and childhood constitute the period of rapid growth, of perfect or imperfect development, of habit formation. Metabolism differs in the child. The reactions to various stimuli are intensified. Not only must the pediatrician be a well trained doctor but for the reasons mentioned special training is deemed necessary for proper diagnosis and the care of the child. The particular preparation necessary for the pediatrician is that of a specially trained "internist" with an age limitation. In actual practice his responsibilities extend from the birth of the baby until the child has reached the age of puberty and are all inclusive not only of illnesses and accidents but also of diet, prophylaxis and general care. In these responsibilities and relationships the pediatrician more closely than any other medical specialist approximates the varied practice and independence of the "old family physician."

Although the pediatrician thus accepts responsibility for the well being of the child, he often finds himself in need of advice and assistance by specialists. The most frequent and continuing necessity for such consultation and assistance is dictated by the dominant role of the upper respiratory tract in the early life cycle of the child. It is the relationship between pediatrician and otolaryngologist that I shall undertake to analyze. Four considerations are of primary concern.

First, and possibly most important, the care and immunization of the well child.

Second, acute conditions involving the upper respiratory tract.

Third chronic infection that affects nutrition and general health.

Fourth, coordination in study for the advancement of mutual knowledge. Physicians, particularly specialists, are too often satisfied with, and rely too largely on, their own experience. One of our medical philosophers, Dr. Abraham Jacoby has said "A man may do the same thing wrong for fifty years and call it experience."

THE CARE AND IMMUNIZATION OF THE WELL CHILD

(a) *Heredity*—Many of the mental and physical characteristics that affect the life of the child are inherited. Shea¹ believes that the sinuses follow closely, not only in conformation but also in their life history, the developmental cycle of the sinuses of the parent the child most resembles facially. Heredity is also a considerable factor in the shape of the bones of the face, particularly the dental arches. Allergy, another hereditary character, is increasingly important. Of the various allergic manifestations seen in the infant and child, from 75 to 80 per cent are now thought to be hereditary.

(b) *Antepartum Care*—The care of the child should begin with the care of the mother during, and even before, pregnancy. Numerous considerations dictate the importance of such antepartum control. For example, fetal rickets with its deformities is now recognized as a well defined entity. Calcification of the teeth begins about the one hundred and fortieth day of life, and at birth the deciduous teeth are fully calcified and the permanent teeth partially so. What is true of the teeth is true of the entire bony structure of the body. Again contagious and infectious conditions occurring during the fetal period may be responsible for deformities that materially influence function throughout postnatal life. With syphilis, if treatment is begun immediately after conception and continued throughout pregnancy, the course of the disease will be favorably influenced even if a cure is not accomplished. A careful family history and thorough physical examination are the first essentials.

(c) *Management of Nutrition*—The undernourished child is less resistant to infection and fails to grow and develop normally. The child whose parents are weaklings, who has a bad home environment or is poorly fed is sometimes described as constitutionally inferior, for want of a better term. This is the type so commonly seen in free clinics. In many such cases the nutrition problem is the only one to be solved.

Pediatricians have long recognized that breast milk is generally the optimum food. However, even breast milk sometimes does not serve all the requirements, depending often on the diet and habits of the mother. There is no uniformly perfect food. Each child is a separate problem. As a growing organism that doubles in weight during the first six months, triples in weight in one year and continues to grow rapidly until after puberty development must keep pace with growth. If certain fundamental nutritional factors are kept in mind and carefully and conscientiously observed, with proper care good results may be had with almost any rational food mixture. The young infant must have sufficient of the energy producing and structure forming foodstuffs, that is, carbohydrates, fats, proteins, mineral salts, and water. Its diet must also include the accessory foodstuffs the vitamins. Plenty of sunshine, fresh air and proper clothing must be provided. Elementary as these requirements may appear, they must be strictly observed to avoid imperfect nutrition and development with resultant deformities. No matter how well balanced the diet, proper nutrition cannot be accomplished without normal assimilation and metabolism. At no other period of life do the secretions from the ductless glands play so important a part.

From the Department of Pediatrics University of Tennessee College of Medicine.

Read before the Section on Laryngology, Otolaryngology and Rhinology at the Eighty-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., June 13, 1935.

¹ Shea, J. J. Normal and Pathologic Development of the Sinuses. Pennsylvania M. J. 37: 270 (Jan.) 1934.

Much has been written about the benefits of special diets for the so-called lymphoid type of child. It has been claimed that a high carbohydrate intake predisposes to hypertrophy of the lymphoid tissues of the upper respiratory tract. The scope of this paper will not permit further discussion than to reiterate that the diet should be balanced in respect of all known nutritional essentials and then fitted to the individual child, frequently by the method of trial and error.

(d) *Immunization*—Since whooping cough, diphtheria and scarlet fever are responsible for many otolaryngologic complications, immunization of the normal child against these three diseases will be discussed.

Whooping Cough There is probably no inherited immunity to whooping cough. It occurs even in the extremely young child. Within the last two or three years immunization against whooping cough has been increasingly undertaken. Sauer² has recently attempted the immunization of a series of young infants at the Cradle, in Evanston, with seemingly good results. Sufficient time has not yet elapsed to permit a conclusive opinion. This method is not dangerous, appears to have considerable value, and deserves further trial.

Diphtheria There is a natural immunity to diphtheria, which seems to persist until about the sixth month. If all infants are immunized at this age and controlled by the Schick test, diphtheria may be eradicated as effectively as yellow fever.

Scarlet Fever Much has been written by the Dicks and others concerning active immunization to scarlet fever. The present general opinion is that scarlet fever immunization is not as effective as is the toxoid for diphtheria.

ACUTE INFECTIONS OF THE CHILD INVOLVING THE UPPER RESPIRATORY TRACT

Brennemann³ has written

Why should a pediatrician, who is a general practitioner to the young, presume to discuss a subject that might seem to belong to a regional specialist? The answer is evident. In the first place, it is because he is a general practitioner and must therefore be usefully informed on one of the most common and most important diseases of childhood. The pediatrician as a rule sees the patients for the underlying throat infection before the ear is involved. If he is a good pediatrician he has long ago found his otoscope as indispensable as his stethoscope and in some cases even more so. By examining all ears in as routine a fashion as he does the chest, he becomes familiar with the normal and with the abnormal through all the stages from the simple redness and congestion, which accompany nearly all nasopharyngeal infections, to the bulging ear that cries for surgical relief. Finally, he is in a position that the otologist cannot occupy—that of being able to size up the whole clinical setting, of which the otitis may be only a very minor part.

On the other hand, in the fully developed otitis and in all complications the otologist has a technical knowledge and skill that the practitioner does not possess. The practitioner must acquire the ability to examine and to evaluate with reasonable accuracy an ordinary otitis media. He will treat it so long as he feels sure that surgical measures are not indicated. If the drum has ruptured and there is free discharge, the experienced pediatrician will not worry because of that fact. Rather, he will be happy to be able to spare the child the pain and psychic trauma of a paracentesis, without adding to the hazard. If the paracentesis seems indicated I have myself always called in an otologist, both as a matter of protection in case of a subsequent serious complication and to give the parents the benefit and the solace of a specialist.

Brennemann has summed up this phase of the subject admirably. A pain in the ear does not necessarily mean suppurative otitis media. The younger the child, the greater the likelihood of infection of adenoids and sinuses with ear involvement. As the child grows older, the tonsil is more frequently involved.

An adequate paracentesis seems to me to be not altogether a minor procedure. Some paracenteses never require repetition, in others, repetition is regularly necessary. Free and proper surgical drainage is essential. Considerable difference of opinion exists as to whether early paracentesis prevents or increases the incidence of mastoid complications. In 1922 I visited two European clinics, in one of which it was the practice to open no acutely involved ears, in the other, paracentesis was performed early. The mastoid incidence was somewhat lower in the clinic where the ears ruptured spontaneously. Whether this fact was due to differences in infection cannot, of course, be stated, but, undoubtedly infection is spread and prolonged in some instances by opening drums unnecessarily, and particularly if aseptic technique is not employed.

Brennemann has also said

In recent years the mastoid antrum without external evidence of involvement but with otoscopic evidence of "sagging of the posterior wall" of the canal has been advanced as a common cause or initiator of severe gastro-intestinal symptoms and intoxications, with striking and fairly constant therapeutic results from antrotomy. That some including myself, have failed to get that therapeutic result may be the result, in part, of timidity based on a priori incredulity, or of a strange vagary of that ever varying and fickle thing we call the genius epidemicus of disease which may have led to a peculiar heaping of favorably reacting cases in one locality or another.

My experience does not agree with that of Brennemann. I have had many cases in which antrotomy has produced definite results.

Recently, a child was admitted to the Baptist Memorial Hospital with a marked condition of pyloric stenosis. A Ramstedt operation was performed. Vomiting stopped. The child began to gain weight. Just about the time the patient was to be discharged an infection of the upper respiratory tract with vomiting developed. The condition became quite precarious. A double otitis media now developed. Roentgen examination of the mastoids showed that both were cloudy. They were drained surgically under local anesthesia. Considerable pus was found. Recovery was prompt and complete.

That the condition of the mastoid as a focal infection of the upper respiratory tract may be very difficult to diagnose is evidenced by the following case.

A boy, aged 2½ years, was admitted to the Baptist Memorial Hospital with from twenty-five to fifty bloody stools daily, marked dehydration, vomiting and high fever. The interesting feature of this case was that it came from the town of Osceola, Ark., from a levee camp where there were at this time numerous cases of true Shiga dysentery. There had been one death in the family, and two others in the family were suffering with dysentery. At the time the child was admitted to the hospital a diagnosis of Shiga dysentery was made clinically and treatment was instituted. Stool cultures sent to the laboratory were negative on three occasions. On the fourth day after admission the child showed a red pharynx and increased nasal discharge. Examination of the ears showed both drums bulging. The mother then on being questioned stated that six months previously the child had had double otitis media following what was called "flu". Roentgen analysis showed both mastoids involved. The mastoids were drained. The child was put on a full diet. No further treatment for the bowel condition was instituted. The child recovered rapidly and gained 9 pounds (4 Kg.) in nineteen days.

² Sauer, L. W. Immunization Against Whooping Cough, *Am J Dis Child*, 49: 69 (Jan.) 1935.

³ Brennemann, Joseph. Otitis Media as a Pediatrician Sees It, *J. A. M. A.* 87: 449 (Aug. 15) 1931.

In a survey of the acute illnesses in the Memphis General Hospital, both in the new-born and in the children's services, covering a period of three years, it was demonstrated that 65 per cent of the infections were upper respiratory in type. A recent epidemic in the new-born service of this institution was characterized by coryza, swelling of the mucous membrane of the nose and throat, marked dehydration, and death in several cases. The portal of infection was undoubtedly the nose. The organism demonstrated was *Streptococcus haemolyticus*. Similar epidemics have been reported in other cities.

Vaccines—Before the discussion of the acute infections is closed, a word may not be amiss as to the value in children of vaccines that are used by some with reported good results in both the acute and chronic types of infection. The value of the vaccines, both autogenous and stock, has been exploited. I believe that an autogenous vaccine is of greater value than stock vaccines. I am using a vaccine designated as the seasonal vaccine. The laboratory isolates the predominating organism from the culture of the infection current in our city. The vaccine prepared from this organism is added to an autogenous vaccine, the mixture being administered in exceedingly small doses. In the chronic cases, vaccination is repeated three times during the year, in the fall, winter, and spring seasons. Five injections constitute a series. In the severe cases of acute and chronic infections, in which the hemoglobin and red cells are low and the child seems to lack resistance, transfusion of fresh blood is indicated, particularly in those instances in which operative procedure is imminent. Comparative results over a period of several years convince me of the value of this procedure in my practice.

CHRONIC INFECTIONS AFFECTING NUTRITION AND GENERAL HEALTH

(a) **Tonsils and Adenoids**—Opinion has changed within the past few years as to the status of the tonsils and adenoids. Only a few years ago I heard a prominent member of this section state that the only good tonsil was the tonsil in the bottle. Since then he has retracted that opinion. Twice within the last year I have heard Dean express the belief that the tonsil has a function, which possibly is to act in some manner not yet demonstrated as a barrier against infection. The life cycle of the tonsil supports this concept of function in that the adenoid or pharyngeal tonsil is most active in the infant, as evidenced by its hypertrophy during this period. Later the faucial tonsil takes over the burden and is most hypertrophied during the period of childhood. The lingual tonsil plays a minor rôle until adult life. The fact that first the pharyngeal and later the faucial tonsil atrophies in the normal child is also significant.

If the tonsil has the suggested function, its removal when healthy in the young child is contraindicated. It has been the experience of Shea and Mitchell that paranasal sinusitis has been much more frequent and more severe in the child who has been tonsillectomized early in life.

Dean⁴ states that the removal of the tonsil should be decided by a history of repeated attacks of tonsillitis or based on definite evidence that the tonsil is acting as a focus of infection, that hypertrophied tonsils and adenoids should be removed only when they obstruct

breathing. A thorough physical examination should be made, including blood clotting time, red blood cell and hemoglobin estimation, and urinalysis. Many bad results will be avoided by this routine. No child should be operated on who shows any evidence of acute infection, whose clotting time is not normal or who evidences any severe degree of secondary anemia. It has been my practice in recent years to give a fresh blood transfusion before operating on a child whose hemoglobin is 65 per cent or less and in whom the indications are that not sufficient time can be allowed to build up the blood condition by other means. I have followed the same procedure prior to operating on chronically infected mastoids in patients who exhibit anemia.

Postoperative Care—Care during convalescence prevents complications. All tonsillectomized children are kept in bed for one week. Kaiser⁵ has shown that the sedimentation time is markedly increased following tonsillectomy.

(b) **Paranasal Sinuses**—Paranasal sinus infection is a condition that interests the pediatrician as much as the otolaryngologist. Most of the chronic sinus sufferers, indeed, are not examined for conditions referable to the upper respiratory tract; the sinus condition is disclosed only in the course of a thorough physical examination. The question may be asked "How is the differentiation made between acutely and chronically infected sinuses?" It has been demonstrated that the paranasal sinuses in a healthy child have a regular cycle of development. I believe that disease inhibits this growth, that chronically infected sinuses do not develop until proper treatment is instituted, that diagnosis of chronic paranasal sinusitis depends on the topography of the sinuses rather than on the degree of cloudiness disclosed by the x-rays. I believe that the child with chronically diseased sinuses is a sinus sufferer throughout life, that unless these sinuses are influenced by proper treatment to grow the individual never becomes entirely normal. I believe further that even up to the age of 9 years, chronically affected sinuses when properly treated will grow and become entirely normal by young adult life. These observations are based on clinical investigation continued over a period of twenty years. If these convictions are true, the time to effect a complete cure is during the period of childhood, that is, the growing period.

My experience has been that the diseased paranasal sinuses do act as foci of infection which are responsible for many chronic complications and that often failure to improve after tonsillectomy is attributed to sinuses that were diseased at the time or subsequently became diseased.

(c) **Allergy**—Allergy undoubtedly plays a prominent rôle in paranasal sinus disease. The allergic individual may have poorly developed sinuses without evidence of other pathologic conditions. In many instances the sinuses of an allergic individual have been drained unnecessarily when the removal of the offending allergic factor would have benefited the patient. On the other hand, in some cases removing the allergic substance alone has not been sufficient to clear up the condition. I have improved the patient only after the infected sinuses were drained in addition to proper allergic treatment.

It has long been recognized that in many children allergy appears after infectious diseases when the resistance of the patient is low. For the same reason, raising

⁴ Dean, L. W. The Tonsils Their Function and Indications for Their Removal. J. A. M. A. 103: 1044 (Oct. 6) 1934.

⁵ Kaiser, A. D. The Relation of the Tonsils and Adenoids to Infections. Am. J. Dis. Child. 41: 568 (March) 1931.

the resistance of an allergic patient suffering from an additional chronic infection will undoubtedly assist in clearing up the allergic manifestations

The father of a boy, aged 8 years, was a sufferer from hay fever, the grandmother on the maternal side had asthma. The child had eczema when an infant. He began asthmatic attacks at the age of 4 years. These attacks were more severe during the spring and summer months. An allergic survey showed that the child was sensitive to all the spring grasses and particularly both types of ragweed. The pollens of several trees also produced a mild reaction. He was likewise sensitive to quite a number of foods, particularly milk, wheat and eggs. An extract was made of the offending pollens. The articles of diet to which he was sensitive were also eliminated. This treatment was continued for three years with little or no improvement. He was first seen by me last winter, when he developed a mild case of scarlet fever followed by one of the most severe attacks of asthma he had ever had. His tonsils had been removed at the age of 3 years. Following his attack of scarlet fever, a roentgenogram of the paranasal sinuses was made. The ethmoids and maxillary and frontal sinuses were found to be poorly developed. The maxillary sinuses were cloudy. A diagnosis of chronic paranasal sinusitis was made. The sinuses were drained in February of this year. The pollen injections and diet regulations were continued as previously. The mother stated that the child has had no asthma since the drainage of the sinuses, and he is in better health now than he has been in years.

Dr J. C. Price,⁶ chief of the tuberculosis service of the institutions connected with the University of Tennessee, states that by far the larger percentage of children diagnosed as having pulmonary tuberculosis are not tuberculous but are chronic sinus sufferers wrongly diagnosed and can be cured only by proper attention to the paranasal sinuses.

(d) *Chronic Mastoid Infection*—This is of particular importance because the presenting symptoms are not always referable to the mastoid. In many instances even a history of mastoid involvement is denied or forgotten. There is no tenderness behind the ear. The canal shows a droop. The drum has a dull, parchment-like appearance. Disease can best be determined by comparison of the two ears when only one is involved. Examination is verified by roentgenology.

In September of last year two brothers, one 14 and the other 9 years of age, were admitted to the charity service of the Baptist Memorial Hospital. The older child was very edematous, with marked ascites. The urine showed four plus albumin and a variety of casts. The blood nonprotein nitrogen was normal, and the blood pressure was not elevated. The child was very anemic. A diagnosis was made of chronic nephritis of the parenchymatous type, or nephrosis. The history was of an otitis media two years previously, and a chronic discharging ear since that time on one side, the other ear suppurated whenever the child developed a cold. The paranasal sinuses were cloudy and poorly developed. The tonsils had been removed. Roentgen examination showed marked involvement of both mastoids. The mastoids were drained and marked destruction found. The child did not improve. This was a case in which neglected diagnosis of the upper respiratory tract as a focus of infection was undoubtedly responsible. The younger brother had had scarlet fever two months prior to coming to the hospital. His face was swollen and edematous, there was no ascites, some puffiness and edema of the extremities were present. The urine was bloody and much reduced in amount, with many red cells and pus cells. The blood pressure and blood nonprotein nitrogen were elevated. The tonsils were enlarged. The paranasal sinuses were poorly developed and markedly cloudy. A diagnosis was made of acute glomerular nephritis with pyelitis. The kidney condition was treated. The child improved, and the amount of urine increased. It was decided to drain the paranasal sinuses and to postpone tonsil-

lectomy. After drainage of the sinuses the child returned home in good condition. Following a second cold some months later he returned to the hospital with a recurrence of the kidney condition. When the acute infection had subsided the tonsils were removed and his condition improved. Undoubtedly in this case the upper respiratory tract was responsible for the kidney infection, and the focus was eradicated in time, before the kidney substance was destroyed.

These two cases are typical of a very large number that could be cited to support my thesis.

COORDINATION IN STUDY FOR THE ADVANCEMENT OF MUTUAL KNOWLEDGE

A recent survey disclosed that 90 per cent of the children in the state of Tennessee were being treated by the general practitioner. I do not have statistics to show what proportion of infections of the upper respiratory tract are being handled by the family physician; undoubtedly, the proportion is large. In somewhat smaller degree the same conditions prevail in the North, East and other sections.

The general practitioner cannot be blamed entirely for the poor pediatric and otolaryngologic care frequently provided. The tendency in recent years to specialize without proper general medical training and experience is largely at fault. With establishment of the National Board of Medical Examiners to qualify specialists and to inform both the profession and the public of those qualified, improvement in this condition may be anticipated.

The general practitioner welcomes the round table discussions conducted by men who are competent because of their clinical experience. The public is now greatly interested in all phases of the care and well being of the child. It is receiving much misinformation, and, in its zeal to do something, is sponsoring movements and programs that are not only useless but actually detrimental.

A campaign of education outlined and conducted by men of standing and experience would be acclaimed and would displace propaganda which the medical profession is now criticizing. As physicians we indict outside organizations for usurping what we consider our privileges. In many instances we have only ourselves to blame for lack of interest and energy. The public has been educated to the point that it now demands certain information, advice and care. In addition to a campaign of education, the medical profession should certainly supervise operative and nutritional clinics for the child. At least one prompt result would be elimination of mass tonsillectomies done without reason and often productive of harm.

CONCLUSION

As a pediatrician, devoted to that branch of medicine which has for its ideal the making of a better next generation, I have often needed, and shall often need, the help of the otolaryngologist.

1073 Madison Avenue

ABSTRACT OF DISCUSSION

DR PERCY WRIGHT, Montreal. Children of the wealthy and of the indigent who become hospitalized receive the best that medical science offers. Those of the middle classes are often denied consultants in protracted cases. With the hospitalized child, intimate correlation of work between the pediatrician and the specialists is maintained. Regarding the four classifications for the first, the otologist is little concerned, for the last three, intimately so. My experience with blood transfusions is good, my vaccine experience is not outstanding. I classify as urgent and give precedence to patients presenting

⁶ Price, J. C. Personal communications to the author.

large infected tonsils, when associated with complications. The hypertrophic tonsil patient and the class referred from routine examinations, with little to warrant tonsillectomy from the laryngologist's point of view, report at intervals for check-up. Confinement of three days for the healthy child is sufficient after tonsillectomy, for the debilitated child, a week may be too short. Paranasal sinus infection and pulmonary disease may have the closest relationship and demand strict coordination between the pediatrician, the surgeon, the radiologist and the bronchoscopist. That the condition of the mastoid and middle ear as a focal infection of the upper respiratory tract is difficult to diagnose is evident. The pediatrician and the otologist must be dependent on each other. Note the cases of improvement after simple myringotomy, and, conversely, the disappointment after a mastoidectomy. No dogmatic rule can be laid down for performing myringotomy, each case should be studied from the pediatrician's and the otologist's point of view better in consultation. I am opposed to incising the injected drum head and to temporizing with a bulging drum. Hospitals demand bacteriologic examination in every case of myringotomy, owing to the prevalence of pneumococcus type III. Cholesteatomatous ears are not infrequent in children.

DR H MARSHALL TAYLOR, Jacksonville, Fla. Dr Mitchell lays special emphasis on the importance of antepartum care and its relationship to the normal development of the child. I predict that within the next few years the subject of antepartum influence and antepartum care will receive more attention than ever before for the profession seems to be awakening to the fact that too many things happen to the unborn child. I agree that the care of the child should begin with the care of the mother during or even before pregnancy. Dr Mitchell says that rickets in the fetus with its deformities is now a well defined entity. From the dentists it is learned that, if there is a deficiency of calcium at the time the tooth buds are formed in the fetus, the teeth will rapidly decay in early childhood and no amount of good dentistry will stop it because the foundation was not properly laid for good teeth before birth. Many of the research workers in the field of otosclerosis are of the opinion that it develops during intra-uterine life owing to deficiency in the food of the mother and to various toxemias and focal infections in the pregnant mother yet up to this time little attention has been paid to the prospective mother who has otosclerosis with the idea of preventing otosclerosis in the offspring. Dr R A Hetler has written about the interrelationship between the concentration of minerals, vitamins and proteins of the diet and its influence on the metabolic normality. The sooner the pediatrician and the otolaryngologist pay due attention to this line of thought in relationship to the mother and the unborn child the sooner may some light be thrown on the dark chapter of otosclerosis. It now seems to be recognized that much of the thyroid dysfunction most often called goiter, in many regions of this country, is due to a dietary deficiency of iodine on the part of the mother before the birth of the child. The conditions that have been mentioned seem to call for a closer cooperation between the pediatrician and the otolaryngologist. If more attention is focused on the diet and care of the prospective mother, steps will be taken toward the laying of the proper foundation for the various structures before birth. If this is done in years to come less may be heard of rickets, dental caries, sinus disease in infants and the lymphoid tendency that predisposes to aural disease.

DR SIMON L. RUSKIN, New York. Children, particularly those who lose a great deal of nasal secretion or any secretions from the mucous membranes, lose nucleoproteins primarily and after a period of time this loss of nucleoprotein manifests itself in the form of a disturbance of water metabolism. Whether it is a nephrosis or an allergy, there is a pronounced influence on the water metabolism through these losses of nucleoprotein. They manifest themselves primarily as a loss of nucleic acid. The protein elements are apparently restored readily, but the nucleic acid elements are not restored except through the diet. In children in whom there is a deficiency of nucleic acid in the diet, disturbances in water metabolism, such as nephrosis and allergy apparently appear. Possibly one of the reasons why patients are seen who do badly after tonsillectomy and adenoidectomy or who develop severe attacks of sinusitis after the removal of tonsils and

adenoids may be bound up with nucleic acid loss. Deficiency of nucleic acid must be considered before tonsillectomy. Since one of the functions of the reticulo endothelial system, the lymph glandular system, the spleen and the thymus is apparently the production of an adequate amount of nucleic acid for the growth and development of the child, it appears important to investigate carefully the question of the loss of nucleic acid prior to any surgical attack on the tonsils or adenoids and to consider this loss carefully in all cases in which there is a continuous secretion of mucous membrane, such as sinusitis, chronic nasopharyngitis, rhinitis, an already established allergic condition or gastro intestinal condition.

DR. EDWARD CLAY MITCHELL, Memphis, Tenn. Regarding the controversy on paranasal sinus infection when I was in the army I had a soldier who persistently stated that the rest of the company was out of step. Perhaps Dr Shea and I resemble that soldier, but our experience obtained by following closely some of these cases for twenty years still leads us to believe that we are right, at least until more definite proof to the contrary is obtained.

GIANT-CELL BONE TUMOR OF COSTAL ORIGIN

PAUL C SAMSON, MD

AND

CAMERON HAIGHT, MD

ANN ARBOR, MICH

Since reference to only nine cases of giant-cell tumors of the rib has been found, the following additional case of this relatively rare lesion is being reported.

C S, a white woman aged 31, admitted to the University of Michigan Hospital in February 1934, complained of an enlarging tumor of the second rib close to the right costochondral junction. Two years previous to admission, the patient noticed a small hard nodule in this region. The tumor slowly progressed in size and became more prominent, especially during the six months prior to admission. There was no history of trauma and there had been no pain or tenderness. Examination showed a hard, nodular tumor, 2.5 cm. in diameter, involving the second rib immediately lateral to the costochondral junction and extending into the first and second intercostal spaces. The overlying skin was elevated about 0.5 cm and was not fixed to the mass. There was no tenderness or redness.

The routine laboratory examination gave normal results and the Kahn test was negative. Detail roentgenographic studies of the rib were reported by Dr Carleton B Perce: "Expanding tumor of second rib, right, proximal to costochondral junction. This proximity suggests probable osteochondroma. Trabeculation and the persistent differentiation of the chondral junction indicates the possibility of a giant-cell bone tumor" (fig 1).

February 28, the tumor was completely excised under local anesthesia. The costal cartilage was divided 1 cm mesial to the tumor, and the rib 1.5 cm lateral to the tumor. The adjacent intercostal muscles were removed with the mass. The tumor was hard and encapsulated and measured 2 by 3.5 cm (fig 2). Convalescence was uneventful. Postoperative irradiation was not given, because the excision was considered complete.

A microscopic examination of the tumor was made by Dr C V Weller. He reported: "After decalcification. Benign giant cell tumor with marked formation of atypical fibrous connective tissue and osteoid tissue. Many multinucleate giant cells of the usual type. This new growth does not invade the costal cartilage and is not sufficiently cellular to be considered sarcomatous. The cartilage itself shows some proliferation which is probably not neoplastic. The adjacent muscles and fascia show no neoplasm. If there is any doubt as to the complete removal of the tumor, irradiation is advisable" (fig 3).

A physical examination and a roentgenogram were made ten months after operation. There was no evidence of recurrence.

From the Department of Surgery, University of Michigan Medical School.

PREVIOUSLY REPORTED CASES

Only nine other cases of giant-cell tumor of the rib have been collected. Six of these have been reported by the surgeons or physicians in whose clinics the patients were treated.¹ Christensen² has collected seven cases, of which three are included among the nine known cases. Two of these three cases are on file

Fig. 1—Roentgen appearance of expanded tumor of second right rib just lateral to the costochondral junction

with the Registry of Bone Sarcoma³ (the unreported cases of Neil, and of the Memorial Hospital Clinic New York), and one is reported only as a listed case, since the record has been lost. Two of Christensen's collected seven cases are those of Fort and of Gatewood; the remaining two were subsequently reclassified as osteogenic sarcoma.⁴ Geschickter and Copeland have mentioned two

cases of giant-cell tumor of the rib, one being the case of Fort and the other that of Hedblom. Clinical abstracts of seven of the nine cases were available and are summarized in the present report.

CASE 1⁵—A B, a white boy aged 11 years, had an eight months' history of tumor of the first left rib and clavicle. The tumor had been previously partly excised. July 23 1913, the first rib, clavicle and a portion of the sternum were removed. Recovery was uneventful. The boy, at the time of the report, had been free from evidence of recurrence for a period of seven years.

CASE 2¹—S M, a white boy, aged 9 years, had a small tumor near the angle of the fourth left rib. There was a history of trauma, and a persistent aching pain had been present in the left shoulder for two months. June 13 1923, exploratory operation and biopsy were done because the neoplasm was believed to be malignant. Postoperatively a "total of 20 gram hours of radium" is said to have been applied within and outside the wound. The patient was examined eleven years after operation and no evidence of recurrence was found.

CASE 3⁶—C H, a white girl aged 14 years had a left posterior subcostal pain for one year. A scoliosis had recently developed. A tumor of the left twelfth rib was palpable. Roentgenograms showed an oval enlargement of the rib with

central destruction and thinned cortex. Oct. 11, 1921, the entire twelfth rib was removed. Radium was placed in the incision and over the skin for a total of 1,800 milligram hours. The patient showed no signs of recurrence when examined thirteen years after operation.

CASE 4⁹—H M, a white girl aged 16 years had had dull pain in the left shoulder for one year. On examination there was dullness at the left apex. Roentgenograms showed an enlarged cystic first rib from the undersurface of which a bony tumor appeared to extend into the thorax. The treatment consisted of three applications of "radium packs." Coley's toxins were injected. Subsequent roentgenograms revealed progressive diminution in the size of the rib and tumor, and recalcification, all active destruction of bone ceased. The patient was examined seventeen years later and was symptom free. No tumor was palpable.

CASE 5¹⁰—Hedblom has cited a single personal case in his collected series of tumors of the bony thoracic wall. The abstract was furnished posthumously through the courtesy of his associate Van Hazel.¹¹ Sister A. white, aged 38, had had severe intercostal pain on the right side for three years, only temporarily relieved by resection of the eighth intercostal nerve. Roentgenographic examination showed a localized destructive lesion of the proximal end of the eighth rib. May 19 1922, a portion of the rib including the tumor was removed. There was no evidence of recurrence after eleven years.

CASE 6⁷—Peirce¹ of the University of Michigan Hospital, has reported the only case in which there was an apparent malignant change in a giant-cell bone tumor of the rib. H N, a white youth aged 17, was struck in the left lower part of the chest posteriorly while playing basketball nine months before admission. One month after the trauma there were increased swelling and pain. Later there was a loss of 20 pounds (9 Kg.), and a dry cough developed. A tumor was palpable over the tenth and eleventh ribs posteriorly. Roentgenograms showed a destructive lesion of the tenth left rib. Irradiation totaling 600 roentgens was given during a four-day period and was repeated one month later. Two weeks after the last treatment the tumor was widely excised, together with the posterior portions of the eighth to the twelfth ribs inclusive and a portion of the lung which had become adherent to the tumor. Death occurred forty hours after operation. Necropsy showed no evidence of metastases. The pathologic diagnosis was given

Fig. 2—Longitudinal section of the tumor removed at operation in author's case. The costal cartilage is at the cipher end of the centimeter scale. The costal cortex is thinned but intact. The central portion of the tumor is soft and glistening in appearance and contains small irregular calcified islands.

by Dr. A. S. Warthin: "A combination of osteogenic sarcoma and giant-cell sarcoma arising in a giant-cell tumor. After decalcification, chondro-osteogenic sarcoma arising in a giant-cell tumor of the rib infiltrating surrounding tissue."

10 Hedblom⁵ Geschickter and Copeland⁴.

11 Van Hazel¹¹ Personal communication to the authors Jan. 22, 1935.

CASE 7¹²—O B, a man, aged 48, had noticed a hard painless swelling of the fifth rib at the costochondral junction six months before examination. Roentgen studies showed an expanded tumor with a well defined thinned cortex. The density was not uniform. The mass was completely excised at operation. There was no evidence of recurrence eleven years later.

CASE 8—Codman¹ has reported the presence of a specimen of giant-cell tumor of the rib in the Warren Museum, Harvard Medical School. The diagnosis was made by microscopic examination. No history is available.

CASE 9—The original record of Christensen's seventh case has been lost and so no details are available.

COMMENT

Clinical data on only eight cases including the present report are available for discussion. Geschickter¹³ has suggested that the rarity of giant-cell tumors of costal origin is perhaps due to the extremely small and relatively inactive epiphyses of the ribs. Giant-cell

Fig. 3—Microscopic appearance of the tumor. Section shows the costochondral junction. The cartilage with a proliferating border is seen at the right. The neoplasm shows a fibrous stroma rich in spindle cells. Osteoid tissue is present. Many large irregular deeply staining multinucleate giant cells are seen at the periphery of the tumor. (Hemalum eosin stain. Zeiss Planar 20 mm lens.)

tumors of the vertebrae are also apparently rare, a total of only twenty-three cases in all having been collected by Lewis¹⁴ and Santos¹⁵. In the majority of the vertebral cases, cure has followed partial excision. The average age in the rib and vertebra groups is less than that of giant-cell tumors in other localities. Five of the eight patients with costal giant-cell tumors (62.5 per cent) and eleven of the twenty patients with vertebral giant-cell tumors (55 per cent) were less than 20 years of age. Geschickter and Copeland⁶ reported that 37 per cent of all their giant-cell tumors in various parts of the body occurred in persons less than 20 years

of age. 34 per cent of Coley's¹⁶ patients were less than 20 years of age, as were 31 per cent of Christensen's and 23 per cent of Gross's¹⁷.

In the group of giant-cell tumors of the rib, diagnosis was made by microscopic examination in seven of the eight cases reviewed. In case 4 the diagnosis was made by roentgen examination and by the response of the tumor to irradiation.

In four cases the tumor was posterior to the costal angle. In two the entire first rib was apparently involved and in two the tumor was at the costochondral junction.

Treatment has been by complete surgical excision in six cases, irradiation in one case, and partial excision and irradiation in one case. The one operative death followed an extensive resection of the thoracic wall for a malignant neoplasm, which apparently arose in a giant-cell tumor. No recurrences have been noted in any of the eight cases, regardless of the type of treatment, the patient with a frank sarcoma, however, died before a possible recurrence could have occurred.

A possible explanation for the absence of recurrence may lie in the histopathologic changes of the neoplasm. Microscopic examination in four cases including our own has shown a fibroblastic stroma predominantly spindle-cell in type. Geschickter and Copeland⁶ have found the predominance of such cells to be usual among giant-cell tumors occurring in the small flat bones, they have designated the type as the "spindle-cell variant." Explaining this stroma as the result of a heightened defense reaction on the part of cortical bone, they point out that it occurs early and nearly circumferentially in the small and flat bones. In giant-cell tumors in various other locations, Geschickter and Copeland⁶ have reported 20 per cent recurrences.

Opinions differ as to the choice of treatment. If a presumptive diagnosis of giant-cell tumor can be made on the history and roentgen examinations, a carefully regulated series of radiation treatments is perhaps the method of choice¹⁸. The restraint of growth rather than the complete destruction of the tumor by lethal irradiation is desirable. Such treatment has usually been successful with giant-cell tumors in other locations. Roentgenograms taken during the course of treatment will usually show a decrease in the size of the tumor, cessation of active bone destruction, and recalcification.

Operative intervention may be indicated if the diagnosis remains in doubt or if the prominence of the tumor is sufficiently deforming to require its removal. Chondromas should, if possible, be completely removed since they usually do not respond to irradiation and since they may become sarcomatous. There is no agreement as to the best treatment of primary sarcoma of the rib. Many roentgenologists believe that irradiation is the method of choice. Many surgeons (Hedblom¹ among others), however, believe that a sarcoma should, if possible, be removed. In three of the cases of benign giant-cell tumor of the rib (Gatewood, Fort, Neil), a malignant growth had been diagnosed before operation. In our case the preoperative diagnosis was "probable chondroma," although the possibility of giant-cell tumor was suggested. Operation was undertaken because of

the likelihood of future sarcomatous degeneration of the presumed chondroma and because of the disfigurement caused by the enlarging tumor

SUMMARY

Giant-cell tumors are much rarer in the ribs than in other bones. Only ten cases, including our own case, are known to us. At present it appears that irradiation is the treatment of choice if the diagnosis can be established with certainty. Conspicuous deformity may indicate the surgical removal of the tumor. In the reported series no case of recurrence has been found whether treatment was by surgical excision, irradiation or both. The prognosis for cure should therefore be good.

THE HAZARD OF THE AUTOMOBILE DOOR HANDLE

REPORT OF SIX SERIOUS INJURIES

SAMUEL McLANAHAN, M.D.

BALTIMORE

Motor vehicles and their annual toll of injuries to pedestrian and passenger alike have received widespread attention. Drastic means have been and are being employed to remedy the many traffic hazards that have in the past contributed so largely to such accidents. Less attention, however, has been paid to the individual vehicle and the mechanism of each injury as it actually occurs. It is true of course that such a thing as "breakable glass" has received legislative condemnation in many states and is rapidly being supplanted by the more dependable "safety glass" and that emphasis has been placed on the use of "blow out-proof" tires. It is also true that attention has been directed in the medical literature toward certain specific fractures, and that these fractures have been named for their association with the automobile. Most noteworthy is the "chauffeur's fracture" of the radius, less often seen in these self-starter days. In addition, reference is occasionally made to the "bumper fractures" of the tibia and fibula sustained by the pedestrian, and two years ago an article appeared by Topping¹ reporting a number of cases of "traffic fracture of the elbow," a serious injury usually befalling the driver whose protruding left elbow is struck by a passing vehicle.

While attention has been directed occasionally to the types of injury just enumerated, little emphasis has been placed on another group of injuries, those resulting from the hazard of projecting objects on an automobile. Such objects include certain types of lights, ornaments, license plates and, most serious of all, the door handles. Most physicians who have attended numbers of people injured by automobiles can readily recall instances of injury caused solely by these objects, and especially by the door handles. It is my purpose in this communication to direct attention to the present automobile door handle as a very real factor in producing serious and often fatal injury, and to make a plea in the interest of public safety and accident prevention that the automobile industry adopt such changes as may reduce this hazard to a minimum. I report briefly six rather striking cases that have come to my immediate attention, four of which have at some time been under my care. In each instance it is to be noted that the door handle of an automobile has been the agent finally responsible for the gravity of the trauma.

REPORT OF CASES

CASE 1—J. F., a white man, aged 25, was admitted to the Union Memorial Hospital on the night of May 1, 1930, seriously injured. While riding a motorcycle he had collided with an automobile, and the door handle of the car had been driven through his skull, burying itself within his head. It had broken off cleanly from its attachment at the door. When examined, he was conscious and mentally alert. There was a wound in the left frontal region from which could be seen to emerge the end of a shiny piece of metal. There was some bleeding from the wound. The left eyeball was ruptured and there was marked extravasation of blood beneath the lids. Roentgenograms (figs 1 and 2) showed the door handle lying almost completely within the cranial cavity. Operation was performed by Dr. J. A. Weinberg, at that time resident surgeon. The foreign body was extracted and the wound was thoroughly irrigated, debrided and closed with drainage. On the following day, enucleation of the left eye was performed by Dr. Cecil Bagley. The post-operative course was uneventful except for some elevation of temperature during the first week and prolonged drainage of serous material from the scalp wound. The patient was dis-

Fig. 1 (case 1).—Position of automobile door handle after it had been driven through the frontal bone.

charged June 23 with the wound completely healed. There were no neurologic changes. Today he is living and able to work regularly, though, of course, markedly disfigured and without the sight of one eye.

CASE 2—M. S., a white girl, aged 11 years, while at play Sept. 16, 1934, rushed out into the street and collided with the side of a passing taxicab. She was thrown to the ground and both she and the cab driver believed that the door handle was responsible for the long deep gash across her chest. A short time later at the Union Memorial Hospital a long wide-open deep laceration was found extending from the left border of the sternum at the level of the third rib across the left side of the chest into the upper portion of the axilla. Wide flaps had been raised on each side. The laceration not only extended through the skin and subcutaneous tissues but included the pectoral muscles and fascia down to the ribs. There was considerable bleeding. Under general anesthesia the wound was thoroughly cleansed and then closed in three layers. Healing was delayed by some slough in the devitalized tissues at the ends of the wound but after four weeks was practically complete. There has remained a rather wide disfiguring scar (fig. 3), which can eventually be excised.

¹ Topping, M. C. Traffic Fracture of the Elbow. J. Indiana M. A. 26: 609-611 (Oct.) 1933.

CASE 3—J C, a white man aged 52, was admitted to the Union Memorial Hospital during the night of Aug 29, 1932 complaining of an injury to his right elbow. He had been walking along a highway on the left side of the road facing traffic. A car passed him traveling at rapid speed, and as it did so the door handle alone struck him, embedding itself in his arm and, needless to say, breaking off from its attachment at the door. Examination at the hospital revealed the right arm in semiflexion and the door handle projecting from the anterolateral surface. It was apparently firmly embedded in the elbow joint. Roentgenograms showed the foreign body wedged between the humerus and the ulna (fig 4). Subsequent films demonstrated a fracture of the internal condyle of the humerus with some displacement. Under general anesthesia the handle was extracted from the elbow but not without the application of considerable force, illustrating well the force that must have placed it there and caused the steel to break off. The wound was closed with drainage. Convalescence was complicated only by considerable swelling and return of function was slow but steady. There remained finally some limitation of flexion at the elbow.

CASE 4²—P K, a Negro aged 28 was crossing the street when he was struck by a passing car. He believed that the door handle of the car caught him in the upper part of the abdomen and tore his flesh. He was taken at once to the accident department of the Johns Hopkins Hospital, where examination revealed a laceration 7 inches long situated in the upper left quadrant of the abdomen. In depth it extended through the skin and subcutaneous fat exposing the thick fascia beneath. The wound was repaired by Dr Erle Henriksen by means of buried sutures of plain catgut and silk in the skin. Some infection occurred in the wound and drainage persisted for several months. At the conclusion of this time the patient was reported as healed and well.

CASE 5²—K B, a white man, aged 22, and a resident of West Virginia was admitted to the Johns Hopkins Hospital April 2, 1935, complaining of a nerve injury in his arm. Nov 23, 1934, while walking in the street he was struck by a passing car, which knocked him over and at the same time

the lower portion of his arm. Examination of the right arm showed muscle atrophy throughout. The hand was rather cyanotic. There were two large scars along the dorsal and ulnar aspects of the forearm, the latter extending down to the ulnar styloid, where the bone was markedly thickened. There was a paralysis of the posterior portion of the deltoid and of

Fig 3 (case 2)—Appearance of scar on chest resulting from laceration by door handle.

all the muscles of the upper arm, forearm and hand. The biceps, triceps and finger reflexes were lost. Sensation was completely gone below the middle of the deltoid on the outer aspect of the arm, and below the elbow on the inner aspect. A diagnosis was made of brachial plexus injury, involving all the roots but sparing the cervical sympathetic nerve. No operative treatment was deemed advisable at this time. The patient had sustained an injury that may well mean the permanent loss of the use of his arm.

CASE 6—W T V, a white boy, aged 16 years, was injured May 12, 1935, while crossing a roadway on a bridge. He was sideswiped by a passing automobile, and his right hand was badly torn by some sharp object. Blood was subsequently noted on the door handle of the car. He was taken at once to the Union Memorial Hospital. Examination of the right hand showed an extensive laceration running from the base of the palm at the wrist throughout the length of the palm and on the middle finger. Two shorter lacerations extended from the original point one running up on each side of the hand. Large flaps were raised between these lacerations exposing the tendons, but no tendons were seen to be cut. Repair was carried out under general anesthesia by Dr A C Dick. After a week there was some slough at the base of the hand because of deficient circulation in the points of the flaps. By June 8 the granulating wound at this point was ready for small deep grafts, which were placed on it. There had been a marked tenosynovitis throughout which caused rather acute pain and limitation of motion. With the aid of physical therapeutic measures, function is gradually being restored, and it is anticipated that the boy will have a useful hand, though a markedly disfigured one.

COMMENT

These six cases illustrate well the bizarre possibilities of such injuries, and the disfigurement and disability that are possible. Ogilvie³ has recently reported six other cases of door handle injuries, two of them fatal puncture wounds of the skull. He has well pointed

Fig 2 (case 1)—Lateral view.

injured his right arm. He was unable to move the forearm or the wrist of the right arm and found that the door handle of the car had torn two gashes in his forearm, probably wedging itself between the bones temporarily. The wounds were sutured at once by his physician, who also splinted his wrist, which was said to be fractured. The laceration and the wrist healed satisfactorily, but the patient was still unable to move his forearm or hand. In addition he had lost sensation, he said, over

² I am indebted to Dr. Dean Lewis for permission to report cases 4 and 5 from the Johns Hopkins Hospital.

³ Ogilvie H. H. Automobile Door Handle Injuries. Texas State J. Med. 31: 910 (May) 1935.

out that the elimination of this one source of danger might reduce materially the annual toll of 35,000 deaths caused by automobiles in this country. A casual glance at a row of passing cars cannot but convince one of the potential danger of this projecting piece of metal. In the recent streamlined models it is to be seen many a door handle that is little short of a spear—truly a vicious weapon—directed toward any victim who may chance to be in its path. The possibilities of mutilation are easily imagined. It is true that many of the handles are directed toward the rear of the car, because the hinges of the door lie in that direction and are thus rendered less menacing though still dangerous projections. Improvements must finally come from automotive engineers. However, there seem to be two requisites for safety: first, a handle (if there must be a handle) without sharp projections, as instanced in the oval ones on certain obsolete models and second a

Fig. 4 (case 3).—Door handle forcibly wedged into elbow joint and broken off from its attachment at the door.

handle that lies either close against or is countersunk within the side of the door. The whole matter has recently been brought to the attention of executives of one of the large automobile manufacturing companies, who have expressed a deep interest and promised earnest consideration. The safety of the person inside the car has been repeatedly emphasized. Now it is time to think more seriously about the person outside the car.

Cardiac Patients—Syphilis should be considered in any case of aortic insufficiency or of heart block developing in an adult. It is not good practice willingly to allow a cardiac patient to call forth his full reserve and consequently to suffer from undue breathlessness or fatigue. Those acts, strenuous or leisurely, which bring distress are to be condemned. A cardiac patient is unfit to be on his feet if, when up, he becomes breathless. Lewis, quoted by Fisher, Alexander. Aphorisms in Clinical Medicine. *Canad J Med & Surg* 77:166 (June) 1935.

ACUTE SUPPURATIVE GONOCOCCIC TENOSYNOVITIS

WALTER BIRNBAUM, M.D.

AND

C. LATIMER CALLANDER, M.D.

SAN FRANCISCO

Gonorrhea manifests itself in many sites remote from its usual portal of entry, the genito-urinary tract. In the literature there are reports of cases of gonococcal thyroiditis, infection of surgical wounds, laryngitis tonsillitis, otitis media, dacryocystitis, parotitis and other conditions. One of the most common focal involvements is that of the joints and less frequently of the related bursae and tendon sheaths.

The only references in English to suppurative gonococcal tenosynovitis, especially that involving the flexor tendons of the hand, are brief notations in textbooks. The condition is recorded by Keen,¹ Howard and Perry,² Da Costa,³ Graham,⁴ Boyd,⁵ and others merely in its relation to inflammation of the tendon sheaths in general. There are a few articles in German⁶ and in French.⁷

Kanavel⁸ has seen only the two patients with gonococcal tenosynovitis mentioned in his book, but he has expressed the opinion that many cases are not recognized or, if diagnosed, are not reported.

It is our purpose in this paper to review the literature concerning acute suppurative gonococcal tenosynovitis and to report two cases. One of these cases was proved and the other was probably of gonococcal etiology.

ETIOLOGY

The primary foci of infection may be the urethra, Bartholin's or Skene's glands, the cervical glands, prostate, seminal vesicles or conjunctiva. It is impossible to determine which of several primary foci acts as the source of dissemination into the blood stream. Focal sepsis without a clinically generalized infection of the blood stream is very characteristic of gonorrhea, the commonest focal infection being so-called gonorrheal rheumatism.⁹ This term includes arthritis,

fibrositis, tenosynovitis, bursitis, myositis and perineuritis. By careful technic the gonococcus in many cases can be isolated.¹⁰ In chronic cases, however, it may be so difficult to isolate the gonococcus that the rheumatic condition may be attributed to a so-called gonococcotoxic manifestation, as described by Villard⁷ and his associates.

Fritz Meyer⁶ cultured gonococci from a flexor tendon sheath of a finger which had been directly infected. The portal of entry was a traumatic lesion.

Acute tenosynovitis may arise also from the direct invasion by many organisms other than gonococci, overaction in working or in sports, metastatic pyogenic infection, influenza, some of the long continued fevers, syphilis, tuberculosis and gout.

More men are affected by this disease than women, the ratio being three to one (Rauschenberger⁹), cases

threads. The walls of the sheath were covered with fungous granulations. A similar case was observed by Macaigne and Finet⁷ in 1894.

Gonococcic tenosynovitis may occur in either acute or chronic forms. Acute gonococcic infection in the tendon sheaths usually is characterized by a mild inflammatory reaction with or without effusion. The severe forms produce frank suppuration. With the production of an exudate, an elongated fusiform swelling of the tendon sheaths may appear.

Jacobi and Goldmann⁶ and others found that the tendon sheaths were filled with thick hemorrhagic pus. The parietal sheaths were red, moist and velvety. Microscopically there was complete absence of the endothelial layer, in its place was a purulent hemorrhagic network that reached to the tendon. Near the inner surface of the sheath was an areola of blood-filled capillaries. There was diffuse infiltration of the synovial membrane by polymorphonuclear leukocytes and intensive proliferation of various connective tissue elements. The gonococci were found only in the phagocytes close to the inner wall of the sheath.

The tendons may show punctate hemorrhages but rarely are destroyed, as they may be in streptococcic and staphylococcic infections. Complete absorption, formation of adhesions and deformation as well as severe disturbances of function may occur following the serous, seropurulent or phlegmonous processes of the inflammation.

DIAGNOSIS

The diagnosis of gonococcic tenosynovitis is made on the basis of a history of venereal disease and the clinical and laboratory observations. It may be difficult to obtain a history of venereal disease because the patient is unable to appreciate any connection between a venereal infection and a distant manifestation. Kanavel¹¹ stressed the importance of considering a hematogenous gonococcic infection in cases of tenosynovitis of obscure origin.

The signs of acute suppurative tenosynovitis are essentially the same as those found in staphylococcic and streptococcic infections: swelling, redness, tenderness along the course of the tendon sheath and limitation of motion. Usually neither the local symptoms (such as pain) nor the general reactions (such as fever and leukocytosis) are as great as in the pyogenic type. In all cases spontaneous or provoked pain is extreme and voluntary movements are difficult or impossible. In our cases there was not the board-like rigidity of the affected fingers, but a five to ten degree range of motion was possible before pain was elicited.

In mild cases without evidence of bacteremia it is so difficult to isolate the gonococci that the question arises as to whether the organism is present in a focal lesion or whether the reaction is toxic. The organisms may be present in the recesses of the joints or tendon sheaths and not be obtained by diagnostic puncture.

Twenty-four hours after the onset of tenosynovitis it may not be possible to demonstrate the gonococci by direct smear, but a positive culture may be obtained. After a few days even a culture may fail to show gonococci. Immediate bacteriologic examination is therefore imperative.

Jundell⁶ of Stockholm in 1894 investigated an infection involving the extensor tendons of the wrist and ankle. He made a diagnosis of gonococcic teno-

Fig. 1 (case 1).—The infected tendon sheath. The tense swelling of the sheath, the lines of incision and the branch of the median nerve supplying the adductor muscles of the thumb are shown.

in children are rare. Dupre⁶ in 1888 reported the case of a 2½ year old girl with gonococcic vaginitis and infection of the extensor tendons of both hands. Diagnostic puncture yielded intracellular diplococci which failed to grow on ordinary culture mediums. Hocheisen⁹ isolated gonococci from the joints as well as from a purulent exudate in the tendon sheaths of an infant with gonococcic ophthalmia.

PATHOLOGY

The sheaths of the extensor tendons, especially those of the common extensor tendons of the fingers, thumbs and toes, are affected most frequently. Pollosson's⁷ case in 1899 was one of gonococcic tenosynovitis of a tendon sheath in the ankle. There the exudate consisted of a purulent discharge in which floated mucous

synovitis by cultivating gonococci obtained from the affected site. He proved it by introducing some of the material into the navicular fossa of the penis of a patient with a brain tumor, thereby producing gonococcal urethritis. A similar procedure was carried out by Aehman⁶ in 1897. Blood from a girl suffering from purulent gonococcal tenosynovitis of the anterior tibial tendon sheath was injected into the urethra of a healthy young man. Not only gonorrhea but also gonococcal arthritis of the left foot and right wrist and tenosynovitis of the common extensor tendon sheath of the toes resulted. The pus obtained from this sheath contained many gonococci.

TREATMENT

The treatment of acute suppurative gonococcal tenosynovitis is surgical and consists of establishing adequate drainage. The reports in the German literature of successful results with vaccines and Bier's hyperemia do not warrant withholding surgical treatment. Hecht⁶ reported a probable case of gonococcal tenosynovitis in which surgical treatment was not given and healing occurred after injections of vaccine. Duncker⁶ presented eighty cases of gonococcal infection of the joints in which there were two infections of the tendon sheaths. These infections were acute and were treated successfully with vaccines. The histories are convincing as to the origin of the tenosynovitis but neither case was proved.

REPORT OF CASES

Two patients with acute suppurative gonococcal tenosynovitis were treated in the University of California Surgical Service of the San Francisco Hospital. Unfortunately, we were unable to obtain complete cultural studies in either case.

CASE 1—F O., aged 20 years, was seen on Dec 31 1933. One week before admission she began work as an usherette in a local theater. This entailed the constant use of a flashlight during working hours so that she repeatedly flexed the right thumb in pressing the lever. Three days before admission she had progressively severe pain and tenderness in the thumb. On the day of entry the thumb became markedly swollen.

Examination showed swelling of the right thumb, the thenar eminence and the radial side of the wrist. These areas were exquisitely tender to the slightest pressure. Motion of the thumb produced pain, extension more than flexion. The tip of the thumb was not tender. The lumbrical spaces were not swollen. Extreme extension of the other fingers caused some pain. There was no evidence of involvement of the ulnar bursa or of the midpalmar space. The dorsum of the hand was edematous. There was no evidence of the presence of a lesion of the skin.

The patient's temperature was 102 F. The white blood cell count was 13,200 with 85 per cent polymorphonuclear cells. An acute hematogenous infection producing acute tenosynovitis was suspected.

After the application of a tourniquet an incision was made as shown in the accompanying drawing (fig 1). When the tendon sheath was opened, about 15 cc. of cloudy, thin, purulent material spurted from it. Cultures were taken but became desiccated before bacteriologic studies could be made. An incision was made on the radial side of the wrist, and more purulent material was found. Petrolatum packs were inserted and a plaster splint was applied.

Later a pelvic examination was made for the first time and revealed the presence of urethritis, Bartholinitis and endocervicitis. The cervical and urethral smears were loaded with typical gram negative intracellular diplococci. The patient had an uneventful postoperative course in the hospital and left with the wound granulating well. She received physical therapy over a period of about two months since which time she has

not reported for treatment. A recent letter informed us that she had regained complete function of the thumb.

CASE 2—E F., aged 23 years, entered the hospital on May 25 1934. Five days before entry the lid of a cake box had fallen on her right index finger but had caused no external lesion or any particular pain at the time. Two days later the proximal phalanx became painful and swollen. Later the dorsum of the hand became edematous, and shortly before entry the right arm up to the elbow became painful and showed lymphangitic streaks.

On examination the proximal phalanx of the index finger was found to be swollen, red and tender, but the middle phalanx appeared normal. The lumbrical space proximal to the index finger was swollen and tender. Slight motion of the finger was possible without pain but further motion caused great distress. Pelvic examination revealed the presence of moderate endocervicitis with evidence of a pathologic pelvic condition on the right side. The urethral smear was positive for gonococci. The patient's temperature ranged from 101 to

Fig 2 (case 2)—The infected tendon sheath of the forefinger. The fusiform swelling and the line of incision are shown. The arrows represent the paths of the pus as it escaped through the perforations in the tendon sheath.

102 F., and the white blood cell count was 11,000 with 88 per cent polymorphonuclear cells.

After the application of a tourniquet an incision was made as shown in figure 2. When the lumbrical space was opened about 3 cc of greenish yellow pus was found. At the proximal end of the tendon sheath were small perforations. Smears and cultures were taken. The smears were positive for gonococci.

The postoperative course was uneventful. The patient was discharged from the hospital four days after entry. In about two weeks the wound had healed completely. The patient because of some legal entanglement, did not have the benefit of physical therapy. When she was seen on July 23, 1934, the wound was healed there was a firm scar and the finger was held in rigid extension with almost no active or passive motion obtainable.

SUMMARY AND CONCLUSIONS

Acute suppurative gonococcal tenosynovitis is one of the less frequent metastatic complications of gonorrhea. It is probable, however, that many cases are not reported.

The infection usually is hematogenous and the possibility of a gonococcic origin should be considered in a case of tenosynovitis of obscure origin

The clinical manifestations are similar to those of the common pyogenic type except that the tendon itself usually is not destroyed

450 Sutter Street

THE MEDICAL TREATMENT OF EARLY PELLAGRA

TOM D SPIES, M D
CLEVELAND

Great interest has been centered in the etiology and treatment of pellagra since its initial description some 200 years ago. Literally dozens of specific materials have been recommended as definite cures for this disease, but through the years there has been no uniform agreement as to either its cause or the best method of treatment. There are two main theories of the cause of pellagra. First, that pellagra is caused by a bacterium. However, no one has been able to isolate any specific bacterium and reproduce the disease. The second theory is that it is caused by the lack of a specific chemical substance present in food. Again, no one has been able to isolate this substance and show its lack to be the cause of the disease. One fact, how-

Fig 1—Well demarcated characteristic pellagrous lesions of the hands. Note swelling areas of desquamation and higher extension of the lesions along the radial portions of the forearm.

ever, is generally accepted, namely, that the mortality rate of severe pellagra is extremely high. For instance, in the Lakeside Hospital, from 1926 to 1930, 54 per cent of seventy-three pellagrins died despite the fact

that they were given the best of hospital care.¹ This high death rate is consistent with reports from other hospitals admitting the severe cases.

During the past five years my associates and I have found certain methods which, when rigidly applied, will reduce the mortality rate in severe pellagra to 5 per cent or less. In deriving this percentage we counted a patient as having died of pellagra even though, in addition to the pellagrous lesions, he had bilateral lobar

Fig 2—Pellagrous dermatitis over the fingers and knuckles and around the vulva and anus. Note the symmetry, clear demarcation of the lesions from the adjacent normal skin and the characteristic roughening of the skin in the lesion.

pneumonia, uremia, carcinoma or some other usually accepted fatal disease. A description of these methods of treatment has recently been published and, while they are effective for the mild or moderately severe case, they are very time consuming and expensive. Here I shall confine my discussion to the treatment of the less severely diseased individual, that is, one without intractable diarrhea, central nervous system changes, or persistent vomiting. After all, the very severely diseased pellagrin is not often seen, for if the disease is recognized early and treated properly it rarely becomes severe. Lay persons must learn that loss of weight and appetite, insomnia and the symptoms of neurasthenia are sufficient grounds to bring one so affected to the physician. At that time the doctor may or may not be able to find diagnostic skin or oral lesions, but an adequate diet, supplemented preferably by at least an ounce of dry brewers' yeast, liver extract or 2 ounces of wheat germ daily, is excellent treatment. These medications, given by mouth, are easily taken and definitely shorten the period of convalescence. It is essential to realize that the yeast and liver extract preparations may vary tremendously in therapeutic efficacy, and for that reason I recommend only the highest grade brewers' yeast purified, assayed, and made highly

1 Spies T. D. and DeWolf H. F. *Am J M. Sc.* 186: 521 (Oct) 1933.
2 Spies T. D. *The Treatment of Pellagra* J. A. M. A. 104: 1377 (April 20) 1935.

palatable and digestible by reputable laboratories. Likewise, the liver extract should be of known strength made and assayed by reputable concerns. The use of an inferior therapeutic material may fail to remit the disease. Prompt treatment of prodromal symptoms is followed by a desire to eat, the ability to sleep and a general feeling of well being.

Oftentimes, however the patient is not seen by the doctor until definite lesions of pellagra are obvious. Some of the early cutaneous manifestations of the disease can be seen in the accompanying illustrations. As I have shown, early recognition of such lesions, good general care of the patient, and the specific use of antipellagic agents produce rapid amelioration of the signs and symptoms. Patients whose symptoms have been progressing for some time but who have not developed the persistent vomiting, the intractable diarrhea or the central nervous system changes of severe pellagra can be treated effectively by a well balanced diet of 4,000 calories or more each day and adequate rest. At times such patients recover with this care alone but it is always wise to supplement the diet with a good brewers' yeast, wheat germ or liver extract. Each must be given in large doses, and only the good products should be used. The wheat germ and yeast have the advantage of being much cheaper than the liver extract. The various yeast products are not equally efficacious, some of them being more potent and more palatable than others. Any one of these agents is best given in doses of from 10 to 20 Gm in a glass of iced milk or iced eggnog, at intervals of three or four hours until the patient receives a total of 75 to 100 Gm daily. The specific care of pellagra is most successful when one resorts to parenteral injection of liver extract, from three to five doses of 20 cc daily, and the simultaneous oral administration of large amounts of brewers' yeast or wheat germ. When stomatitis and glossitis are present and adequate therapy has been administered the condition of the mouth rapidly improves.

Although tincture of opium, 2 cc up to 5 or 6 cc daily may be used in the treatment of diarrhea it is not usually efficacious. Diarrhea ceases only when the patient is cured of pellagra. Treatment must be carried on despite abdominal pain or vomiting. Sometimes a large sedative relieves these conditions and enables the patient to rest better. If the disease has not progressed too far, the involvement of the nervous system is relieved without specific therapy. The skin lesions of pellagra improve rapidly whenever suitable general therapeutic measures are applied. Mild antiseptics, such as potassium permanganate in 1:5,000 solution, used as soaks are often beneficial.

When the patient looks and feels better, gains weight, has a desire to eat and ingests a large and well balanced diet he is on the road to recovery. It is important, however that he be watched for a period of at least two to three weeks to make certain that there is not a relapse. Even after that, special attention must be given to afford protection to these patients, who have such predisposing conditions as poverty, chronic alcoholism, acute and chronic infectious diseases, poor teeth, diabetes, dietary idiosyncrasies, and diseases of the gastrointestinal tract.

SUMMARY

I have shown some methods that have been proved effective in the treatment of mild and moderately severe pellagra. For the best results it is essential that the

physician pay careful attention to the general hygiene and food intake of the patient, and that he employ judicious care in the selection and use of specific therapeutic agents.

2065 Adelbert Road

ABSTRACT OF DISCUSSION

DR. HENRY L. BOCKUS, Philadelphia. In the few cases of pellagra that I have seen in Philadelphia there is usually evidence of some other deficiency in addition to the pellagroid syndrome. I have reviewed the last six cases admitted to the Graduate Hospital. The common factor was alcohol and a pellagroid syndrome. Three of these patients had a true achylia after a histamine test meal, two an achlorhydria without histamine and one a marked hypochlorhydria, so that in the alcoholic pellagrins a deficiency in gastric secretion is to be expected and may be partially responsible for the multiple manifestations of deficiency so often present. In one case there was an associated scurvy, in another extreme hypoproteinemia and polyneuritis. The onset in a third case was ushered in with gastro-enteritis and there was a concomitant hypochromic anemia and portal cirrhosis. The fourth case presented dysphagia, hypochromic anemia and achylia, closely resembling the so called Plummer-Vinson syndrome. The initial phenomena in the fifth case were extreme diffuse inflammation of the mucous membranes and nervous manifestations. The sixth case was complicated by an alcoholic neuritis and wrist drop. A survey of this small series of alcoholic pellagrins indicates a difference in the character of onset and in the systems primarily involved, although the pellagroid syndrome eventually emerged and seemed predominant. I would make a plea for individualization in management, supplying in each case ample utilizable agents to bolster up the various deficient factors that are encountered—vitamin, liver, desiccated hog stomach, hydrochloric acid, proteins, calcium, iron, and so on. Large doses of liver parenterally, as recommended by Dr. Spies and blood transfusions seem to be of most value in the extremely ill patient. A final word of caution concerning the development of pellagra in a nonalcoholic patient outside the pellagra belt: one must be sure to eliminate obstructing and ulcerating lesions in the gastro-intestinal tract.

DR. W. H. SEDRELL JR., Washington, D. C. It was first demonstrated in the laboratory in which I work, in experiments on dogs that liver extract contained the pellagra-preventive factor. There have been several workers in this country who have reported almost uniformly successful results with the use of liver extract in the treatment of pellagra. I think, however, that Dr. Spies has studied this phase of the subject more thoroughly perhaps than any other man in the country. There are just one or two things that I should like to emphasize about the treatment of pellagra with liver extract. One is the cost of treatment by using the large amounts of liver extract recommended by Dr. Spies. That is a factor to be considered. I do not mean to say that one should not use liver extract. If the patient can afford it, it is very good to use. However, dried yeast is very effective and relatively cheap and should I think be given serious consideration. In addition to this as Dr. Spies himself has emphasized, the diet should be improved at the same time. After all, that is the essential point. If the patients leave the hospital and go back to the deficient diet on which they develop pellagra, they will more than likely have pellagra again the next year. The individualization of treatment is another very important point, which Dr. Spies also mentioned. The patient must be watched closely and the physician himself must see to it that he actually gets the prescribed diet and medication.

DR. L. K. RIGGS, New Brunswick, N. J. There seems to be rather a wide margin between the observations of the experimental laboratory and the clinical application. I think that the reason for this is the rather sudden, dramatic effects that can be obtained in all sorts of deficiency conditions which are produced in the laboratory, because the essentials in the laboratory experiment are generally controlled, while various clinical factors which are contributing to the laxness of certain vitamins are frequently due to the fact that the controlling

factor has been either neglected or forgotten, the great factor of the otherwise adequate diet. I don't suppose that any subject of vitamins has been given more general discussion or more conflicting opinions than the so-called vitamin B or vitamin D. This whole thing has been made cloudy by the too general use of the word pellagra. To evaluate clinically or otherwise one of the vitamins, there is one great, important thing which must be taken into account, the remainder of the diet. It has recently been shown in my own laboratory that animals which develop vestibular disturbance due to lack of vitamin B₁ are readily cured by doses of a certain amount of a vitamin B₁ preparation. If, however, those animals were previously on a very low, minimal amount of vitamin B or B₁, it takes a larger amount of vitamin B to cure that condition. But if the reverse is true, that amount of the animal fat which is necessary to effect amelioration depends on the remainder of the dietary requirements.

DR. A. A. HEROLD, Shreveport, La. I am glad to hear Dr. Bockus refer to the "syndrome of pellagra," in Louisiana where a great deal of it existed a number of years ago, it came to be called a "symptom complex" rather than a disease, by that I mean that some patients have one manifestation and some another while others have several, and I have seen it develop as a terminal stage of wasting diseases. It is known that through the education which has been carried on, if the milder cases are treated with the proper food, including the vitamins that are missing they can be cured easily. But what is one going to do for the patient who is bedridden, whose tongue looks like raw beef whose saliva is constantly dribbling because the throat is so swollen that he cannot swallow, and whose bowels are acting twenty, thirty or forty times a day? There were many such cases as these about twenty years ago in our territory comprising certain portions of Louisiana. At that time the late Dr. Goldberger of the U. S. Public Health Service was making his investigations; he told me that there was something lacking in the diet. He did not know exactly what it was, but he thought that it was of a protein nature. About that time I had such a case. The patient wouldn't or couldn't swallow, she was practically hopeless. I figured that there was something needed and needed quickly. Investigators had shown that the coagulation time of the blood is lengthened in pellagra. In trying to find something that would supply protein quickly and at the same time accelerate the coagulability of the blood I decided to use normal horse serum which can always be readily secured. I obtained surprisingly favorable results in this and other cases and I reported this method, which is now used in some hospitals, in a paper read before the Louisiana State Medical Society. I do not claim that this is a specific for pellagra but I do claim that it will tide over patients who are severely ill.

DR. RUSSELL L. HADEN, Cleveland. Dr. Spies has shown me from time to time his interesting patients discussed here today, so I can testify from first-hand observation as to the dramatic results he has obtained. I should like to emphasize that Dr. Spies has dealt with these patients in large numbers and has reduced the mortality in one single hospital from 54 per cent to 5 per cent. Nothing could prove better the value of the treatment that he has instituted.

DR. TOM D. SPIES, Cleveland. I have nothing to add to what has been said. I think that probably one of the most significant things, from the standpoint of the future in the work, is brought out in the statement by Dr. Riggs about the difference between the laboratory observations and the clinics. I hope I did succeed in what I am trying to portray today. I trust that it will be accepted as something worthy of consideration and that these methods will be applied to the mild cases. In regard to the severe cases, I would appreciate very much having a reprint of Dr. Herold's article, for I don't know whether horse serum is better or not, I have never used it. If it is better I am all for having it.

Materials Rich in Vitamin B—Wheat germ and yeast are perhaps the richest in vitamin B of the materials ordinarily available.—Sherman, H. C. Food and Health. New York: Macmillan Company, 1934.

Clinical Notes, Suggestions and New Instruments

A NEW METHOD OF STAINING BLOOD PLATELETS

R. B. H. GRADWOHL, M.D.
Pathologist to St. Louis County Hospital
St. Louis

The method described here is a modification of that described by Fonio. Reagents used in the technic are as follows:

Fourteen per cent magnesium sulphate solution. Dissolve 14 Gm. of chemically pure magnesium sulphate in enough distilled water to make a total of 100 cc. Filter through filter paper.

Methyl alcohol. Uniformly good success has been obtained with the methyl alcohol furnished by the National Aniline Company, and other brands now on the market have failed to give equal success. It is for that reason that I specify the use of National Aniline Company methyl alcohol. The alcohol used in fixing blood platelet smears should be labeled "for blood platelet counting." It must not be used for fixing blood films.

Giemsa stain. I recommend the Giemsa stain that the Gradwohl Laboratories have prepared for this purpose, following Professor Giemsa's original formula.¹

Neutral distilled water. For the testing of neutral distilled water the following method is advised:

Pick up a few crystals of hematoxylin with a pair of metal forceps and place in a glass test tube. The tube should be neutral and contain no traces of acid or alkalis.

Add about 5 cc. of the distilled water to be tested to the hematoxylin crystals.

The water will turn yellow, pink, or a deep purple.

If it turns to a pink color between two and five minutes, the water is neutral.

If it becomes pink before one or two minutes, the water is alkaline.

If it remains yellow for five minutes or longer, it is acid.

In neutralizing acid water use 1 per cent sodium or potassium carbonate solution.

In neutralizing alkaline water use 1 per cent hydrochloric or acetic acid solution.

The neutralizing agent is added to the water a drop at a time, the mixture is shaken after the addition of each drop, and then the water is tested with hematoxylin crystals.

About 2 liters of water may be neutralized at a time.

It is well to test water each day since sometimes it becomes acid or alkaline on standing.

Fresh distilled water should be prepared every few days to insure good results.

Rubber connections on the water bottle should not be used since the rubber from the tubing causes changes in the water that interfere with the staining.

TECHNIC

Immerse the patient's hand in a pan of hot water to produce hyperemia. Wipe the skin dry with a clean piece of sterile gauze. Place 1 drop of magnesium sulphate solution on the end of the finger and puncture through the drop. Allow the blood to ooze through the magnesium sulphate solution until there is a mixture of about 1 part of blood and 9 parts of magnesium sulphate. Mix with the needle point. Pick up a drop of the mixture and place on a fat-free slide. Smear with a cover glass as for a blood film. The cover glass should be narrower than the slide so as to obtain margin-free smears. Fix in methyl alcohol for five minutes (in a Koplun jar).

Wash thoroughly in neutral distilled water to remove any remaining traces of magnesium sulphate solution.

Prepare diluted Giemsa stain by adding 5 drops of Giemsa stain to 5 cc. of neutral distilled water, shaking slightly after the addition of each drop. Do not shake too vigorously.

Flood the slide with the stain on a staining bridge for thirty minutes.

Wash in neutral distilled water
Flood the slide with dilute fresh Giemsa stain and restrain
for thirty minutes
Wash in tap water, dry and examine

METHOD OF MAKING COUNT

Count all the erythrocytes and blood platelets in consecutive fields until 250 erythrocytes have been counted. Count four such fields after the four-field meridian method.

Calculate the number of blood platelets in 1 cu mm of blood by the following formula:

$$\frac{\text{Patient's red count}}{1000} \times \text{number of blood platelets counted} = \text{number of blood platelets in 1 cu mm of blood}$$

EXAMPLE

One thousand red blood cells are counted. Sixty-five blood platelets are counted. Patient's erythrocyte count 5,000,000.

$$\frac{5,000,000 \times 65}{1,000} = 325,000 \text{ blood platelets in 1 cu mm of blood}$$

Normal, from 250,000 to 300,000 per cubic millimeter.

With the Fomo method there is often precipitation of the Giemsa stain, which constitutes a confusing factor in making this count. With the method described, I have eliminated this precipitate and have no difficulty in making a blood platelet count.

This method of staining also gives a deeper stain of the blood platelets, which is highly advantageous in this procedure.

TRAUMATIC FRACTURE OF PENIS

HAMILTON W. MCKAY, M.D. AND G. AUDREY HAWES, M.D.
CHARLOTTE, N. C.

In reviewing the literature of penile injuries, one is greatly impressed with the paucity of case reports, which indicates that either the penis is seldom injured or that physicians do not consider such cases important enough to report. In the World War Young recorded only forty-three penile wounds among the American forces. This is an astounding statement when one considers the exposure of the penis to accidents, vicious attacks, and occasional perversions. Many of the recent text books on urology merely refer to fracture of the penis without discussing its diagnosis, treatment and prognosis. Traumatic rupture of the corpora cavernosa is considered ridiculous and unheard of by many members of the medical profession. Rupture is rare but can cause serious complications. The gravity of the injury depends on whether the urethra is injured or compressed by a blood clot causing urinary retention, or whether extensive rupture of the erectile tissue has taken place. If the rupture is extensive, the resultant scar tissue and contraction may cause a lateral deformity of the penis which causes pain and interference with coitus.

PATHOLOGY AND ANATOMY

The lesion consists of a tear in the fibrous sheath of the corpora cavernosa. The tunica albuginea is a tough dense fibro-elastic sheath, which encircles the corpora cavernosa. This sheath is composed of two layers of fibers: an inner concentric layer and an outer longitudinal layer. From the inner layer arise numerous fibrous septums forming irregular spaces or areolae, which form the supporting framework for the blood vessels. The erectile tissue of the penis is known as the corpus spongiosum and consists of the bulb body and glans. External to the corpora cavernosa is Buck's fascia which binds all the structures together.

DIAGNOSIS

Diagnosis is not difficult as a rule. The patient usually gives a history of an unusual penile injury during erection. On physical examination there is marked edema and bluish discoloration, which extends to the scrotum and a lateral deformity of the penis opposite the injured side. One can usually palpate the tear in the fibrous sheath.

TREATMENT

The consensus is that conservatism rather than radical procedures should be employed. First the patient should be catheterized to determine whether the urethra has been injured and if so, whether a blood clot has occluded the lumen. If the urethra is injured, one should proceed in the usual manner for treatment of urethral trauma, which is not considered in this report. On the other hand, if a blood clot is obstructing the lumen of the urethra a small incision should be made, the clot removed and the bleeding points ligated.

When the urethra is not injured, either cold or hot compresses and sedatives usually suffice. If the effusion continues, the bleeding vessels should be ligated and the sheath sutured.

PROGNOSIS

The prognosis depends on the extent of the rupture. If the urethra is not damaged and the rent in the sheath is small, the parts usually return to normal. If more extensive, the prognosis should be guarded, in view of the resultant cicatrix and deformity.

REPORT OF CASE

C. G., a white man, aged 30, married, was seen Nov. 3, 1934, in an excited, worried state. At 7 a. m. he awoke with an erection of the penis. When he turned over in bed, the penis stuck in the mattress and he thought that it "broke" because

Reproduction of drawing from photograph as the penis and scrotum appeared when patient was first seen showing marked edema of the entire penis especially the foreskin also the firm swollen area on the left lateral surface of the base of the penis. The inset is a cross section through the fracture area showing the accumulation of old blood in the left corpus cavernosum.

it sounded like the breaking of a corn stalk and was followed immediately by severe pain. The entire penis soon became edematous and assumed a bluish red discoloration, which extended throughout the scrotum. There was no history of gonorrhea or syphilis.

Physical examination was essentially negative, except for the external genitalia. The penis was enormously swollen and edematous and was bent to the patient's right. The organ was bluish red, which coloration had extended throughout the entire scrotum, owing to the escape of blood into the subcutaneous tissue.

The patient voided urine with some difficulty but no macroscopic or microscopic blood was present, indicating that the urethra was intact. On palpation one could feel a hard nodular mass unquestionably a blood clot, located in the left corpus.

Examination of the urine gave negative results throughout. Blood counts gave normal results except that the leukocytes numbered 11,250. Hemoglobin was 95 per cent.

Since the patient was able to void urine and there was no hematuria present, catheterization was not deemed necessary. For the first two days, treatment consisted of hot boracic acid steams to the penis and scrotum. On the third day a small incision was made over the blood clot and the clot partially

removed. During the next week the treatment consisted of hot boric acid steams for thirty minutes twice a day.

Ten days after the patient was first seen the penis and scrotum had practically returned to normal, only a slight bluish discoloration remaining. He states that when an erection occurs there is no lateral deformity and very little pain at the site of injury.

NONSURGICAL REATTACHMENT OF IRIS IN A CASE OF TRAUMATIC IRIDODIALYSIS

VIRGIL J. SCHWARTZ, M.D., MINNEAPOLIS

S. K., a boy, aged 12, suffered an injury to the left eye on July 4, 1929. A small torpedo exploded, causing a large iridodialysis above. The iris was torn from its attachment superiorly to the ciliary body for a distance of 6 or 7 millimeters forming the customary D shaped pupil the flat side being, of course, above. There was some blood at the bottom of the anterior chamber. The fundus was not visible and the visual acuity was reduced to light perception. Instillations of atropine 0.15 Gm., cocaine 0.5 Gm., in distilled water 15 cc., were given. In addition, the eye was bandaged, the patient was put to bed and warm applications were ordered. The pupil responded promptly by dilating well, the iris being pushed well toward the periphery of the anterior chamber immediately. After

Iris completely reattached to ciliary body. The separation extended a distance of 6 or 7 mm across the upper part of the anterior chamber.

forty-eight hours the dilatation was not so complete as desired, therefore, a 2 per cent solution of atropine was substituted for the first, and this was used only twice a day, because the patient was having considerable pain and the instillations aggravated this discomfort.

On the night of July 7 the patient experienced a sudden severe pain in the left eye and on inspection it was found that a fresh hemorrhage had filled the anterior chamber. It was a question whether or not there was a hemorrhage in the posterior segment, since it was impossible to see behind the lens from the beginning. For this reason it was not known whether there was a hemorrhage into the vitreous, a detachment of the retina, or whatever else may have transpired. July 8 the blood in the anterior chamber became largely absorbed, and during the succeeding week all the extravasation disappeared. A red reflex began to appear in the interior of the eyeball on illumination although the fundus could not be distinctly made out. Some days later the patient was able to count fingers but it was also becoming apparent that one edge of the lens had been ruptured by the original injury and that opacification was beginning. This gradually increased. July 30 it was possible to make out a fairly large dark hemorrhagic mass below and nasally in the vitreous. This probably represented the remains of a former vitreous hemorrhage. August 23 long after atropine had been discontinued it was evident that the iris had become completely reattached where it had been torn away from the ciliary body above. This condition has not changed since that time. It might be well to mention, although it is not pertinent to the subject in question, that a complete cataract

developed. This was needed in July 1934, and the patient now has a clear pupil, clear media and a normal fundus.

Considerable importance attaches to this case because of the fact that reattachment of an iris once torn away from the ciliary body has usually been regarded impossible. Fuchs and other authorities have held this view. Operations have been devised for drawing the torn iris margin outward and suturing it in such a manner as to reunite the separated edges, but I believe this is a difficult and not altogether satisfactory procedure. However, I can readily see how it might sometimes be advisable if spontaneous reattachment does not occur, and if the dialysis is in a zone that is not covered by the lids when the eyes are open. Monocular diplopia is apt to be a very distressing symptom in such conditions, and for this reason some operative procedure may have to be attempted. A few years ago Shedlov¹ reported a similar case of spontaneous reattachment. Aside from this I know of no other authentic instance, although there may be some.

CINCHOPHEN POISONING WITH AUTOPSY

REPORT OF A CASE DUE TO CINSAVESS

SAMUEL PELUSE, M.D., CHICAGO

Fatal cinchophen poisonings due to various proprietary preparations have been reported quite extensively by Johnson,¹ Weir and Comfort,² Parsons and Harding,³ and others in the recent literature. The case I am reporting is prompted by the peculiar circumstances involved in the patient's death, and by the fact that the preparation consumed is a rather recent addition to the proprietary cinchophen compounds.

Cinsa-Vess, an effervescent tablet containing as its essential ingredients 5 grains (0.3 Gm.) of cinchophen and $\frac{1}{200}$ grain (0.0003 Gm.) of colchicine, appeared for the first time on record in the files of the Council on Pharmacy and Chemistry in November 1930.⁴ The patient consumed thirty tablets of this product over a period of three months prior to the first signs of jaundice, a quantity equivalent to 150 grains (10 Gm.) of cinchophen and one-sixth grain (0.01 Gm.) of colchicine.

REPORT OF CASE

History—Mrs. N. B., aged 37, white, widowed, was admitted to the Mother Cabrini Hospital, Oct. 9, 1934, accompanied by her family physician, Dr. Salvatore Mirabella. The following history was obtained. For the past five weeks she had experienced cramplike pains in the right upper quadrant of the abdomen, and these attacks had become increasingly severe. Four weeks previously she became aware of a yellowish discoloration of her skin and this had progressively deepened in intensity. Her stools were gray at the time of admission, and the urine was very dark brown.

The past history was essentially negative, except for repeated attacks of epigastric distress, especially after eating fatty foods. The physical examination revealed that the patient was well developed and well nourished, and intensely jaundiced with icteric sclerae, and that there was marked tenderness in the upper right quadrant of the abdomen on palpation. The temperature was 97.6 F., the pulse 92 and the respiration rate 24.

The routine laboratory work done on admission was as follows: hemoglobin, 80 per cent, erythrocyte count, 4,210,000, color index, 0.9, white blood count, 12,000, differential white count: small lymphocytes 10 per cent, large lymphocytes 2 per cent, and polymorphonuclear leukocytes 88 per cent. Coagulation time, with a modified Sabrazes method, revealed no coagulation in sixty minutes. Bleeding time, with Duke's method, was complete in thirty minutes. The van den Bergh test resulted in an immediate indirect positive reaction. The blood

⁵ Communication from the Council on Pharmacy and Chemistry and the Bureau of Investigation.

Wassermann reaction was negative. The urine showed a moderate amount of albumin, bile was present in large quantities there were many pus casts, many pus cells and many renal epithelial cells.

The treatment instituted was symptomatic with the addition of intravenous administration on alternating days of calcium gluconate 10 cc of a 10 per cent solution, and 50 cc of a 50 per cent solution of dextrose. Under this regimen after a period of four weeks, the coagulation time had dropped to fifteen minutes and the bleeding time to twelve minutes.

Clinical Course—During the first week in the hospital the patient was seized with daily paroxysms of pain in the right upper quadrant of the abdomen, associated with abdominal distention but these were relieved readily by the usual therapy. The jaundice progressively increased in intensity.

In the second week definite signs of ascites were elicited. The jaundice at this time, when viewed in good daylight took on a peculiar, golden yellow shade, quite different from any jaundice with which we were familiar. This golden tint was most pronounced on the forehead and upper eyelids.

During the third week a progressive edema of the lower extremities developed, extending to the hips, this persisted to the end.

In the fourth week the ascites was marked, causing the patient respiratory distress, while the paroxysms were more intense and increasing in number. In this week on November 6, we were accompanied by one of our colleagues, Dr Andrew Sullivan, on our ward-walk, and he immediately recognized the patient's clinical picture as one due to cinchophen poisoning.⁵ The patient admitted, for the first time, that she had consumed Cinsa-Vess, giving us our first clue to the possible etiologic factor.

On November 11, in the fifth hospital week I gave the patient a transfusion of whole blood, using the Scannell apparatus. After 200 cc had been administered the patient started to cough and showed signs of distress. The transfusion was stopped immediately. The patient, however, became practically pulseless almost at once and failed to rally in spite of the stimulants and restoratives administered.

Autopsy—On examination the body was about 5 feet 2 inches (157.5 cm.) in length, weighed about 140 pounds (63.5 Kg.), and was not in rigor mortis. There was hypostasis in the dependent portion and pitting edema of the lower extremities up to and including both hips.

In the chest there was found about 1 quart of heavily bile-stained, serous fluid in each pleural cavity. In the abdominal cavity there was about 10 quarts of a similar fluid.

The liver weighed 580 Gm. On gross examination the external surface was irregular, due to variously sized elevated yellow brown nodules. A cut section showed variation in color, periphery of yellowish brown and central portions of purplish red. Microscopic examination showed a marked absence of hepatic cells, the areas being replaced by a granular debris, in which were interspersed many biliary ducts. There was a general invasion of the tissue by polymorphonuclear leukocytes and lymphocytes. Areas of small nests of hepatic cells in various stages of degeneration were noted. Retention of bile pigment was present. Other areas showed a tendency of beginning fibrosis. The laboratory diagnosis was acute yellow atrophy of the liver.

COMMENT

The immediate cause of death in this case was, no doubt the effects of the blood transfusion. Clinically the patient presented the picture of "anaphylactoid shock" most likely due to the inability of the damaged liver to handle the serum protein of the donor.

The files of the Council on Pharmacy and Chemistry as well as those of the Bureau of Investigation⁴ up to the present time contain no record of any fatalities caused by Cinsa-Vess. This death, in all probability, is the first recorded from the effects of this compound.

1200 Gilpin Place

⁵ Dr Andrew Sullivan had recently survived a toxic jaundice due to cinchonism and was thoroughly conversant with the signs and symptoms of cinchonism poisoning as well as with the cinchonin proprietary preparations.

HEMOLYTIC ACTION OF CEVITAMIC (ASCORBIC) ACID

HAMILTON H ANDERSON M D AND C D LEAKE PH D
SAN FRANCISCO

It has been recommended¹ that cevitic acid, when administered parenterally be dissolved in distilled water and neutralized with one-half its quantity of sodium bicarbonate in order to avoid tissue sloughing. Another note of caution appears to be warranted in connection with its intravenous use. A patient was given 100 mg of cevitic acid N N R dissolved in 10 cc of sterile distilled water by vein and had a chill immediately after the injection, followed by fever and general discomfort. The reaction was thought to be due to the hemolytic effect of the acid, since blood aspirated into the syringe containing the drug solution was laked immediately. This prompted an inquiry into the hemolytic action of neutralized and unneutralized cevitic acid dissolved in either physiologic solution of sodium chloride or distilled water.

Briefly it was noted that concentrations of 1:1,000 or stronger of natural or synthetic cevitic acid in physiologic solution of sodium chloride or water cause human blood cells to hemolyze at once. Within thirty minutes acid hematin forms in these concentrations, which are acid to litmus. No hemolysis occurs within forty-eight hours in dilutions of 1:5,000 or weaker of the acid in 0.9 per cent sodium chloride solution. Red cells do not break down when in contact with 2 per cent or less sodium cevitamate dissolved in physiologic solution of sodium chloride. Water solutions of the sodium salt less than 3 per cent are hypotonic and thus may cause hemolysis.

On the basis of these observations it is suggested that for intravenous use solutions of the sodium salt of cevitic acid (ascorbic) acid approximate isotonicity, i. e., 1 per cent of the salt dissolved in physiologic solution of sodium chloride or 3 per cent in distilled water. If only the acid is available it should be neutralized with one-half its weight of sodium bicarbonate (sterile) in physiologic solution of sodium chloride or water before it is injected.

CLINICAL COMPARISON OF DRUM AND SPECIAL ETHERS

M S DOOLEY M D C J WELLS M D J C FREY M D F H
KNOFF M D W J GABEL M D J S MORDELL PH G J J
BUETTNER M D C E McELWAIN M D AND C D
BENTLEY M D SYRACUSE N Y

The Golds¹ have recently supplied data controverting the tradition that U S P ether undergoes rapid deterioration when exposed to the air. More recently, Hediger and Gold² have secured data from 702 clinical anesthetics substantiating the earlier laboratory results. These were given in routine manner except that the anesthetists were unaware of the type of ether given ("blind test"). Bulk (drum) ether U S P, freshly opened quarter pound cans of ether U S P and quarter pound can "special" ethers from different manufacturers were used. The only assurance the anesthetists had was that the presence of the supposedly deleterious substances (acids, aldehydes and peroxides) were always within the limits of tolerance of the U S P X. Such assurance was based on U S P and other tests (Nessler and potassium iodide) on each lot on the day used.

These results were of interest to us because our own experience had led us to the suspicion that in some cases at least

different brands of ether from the same manufacturer differed only in packaging, advertising and pricing

We were therefore interested in making independent clinical tests ("blind tests") at the suggestion of Dr Gold, using the same tests of purity as were employed by the Golds.¹ The small cans of "special" ethers were opened as usual at the time used, whereas some samples of bulk ether U S P were used one month after the container was first opened, so that any advantages of freshness were in favor of the former. The tests were in no way unlike the usual routine ether anesthetics of the hospital, save that the anesthetists filled in the special blanks provided for the tests and were ignorant of brands of ether involved. The blanks used were the same as those used by Hediger and Gold² with minor additions. The accompanying table shows the condensed results of 143 anesthetics.

Summary of One Hundred and Forty-Three Anesthetics

Type of Ether	Number of Cases	Male	Female	Anesthesia		
				Satisfactory	Fair	Unsatisfactory
Mallinckrodt for anesthesia 1/4 pound can (white label)	49	24	25	41	1 + 1 (no record) uneven (alcoholic)	0 2 uneven suffocation (1 alcoholic) 2 uneven coughing (1 neurotic) 1 uneven slow induction 1 uneven coughing partial suffocation (alcoholic obese)
Mallinckrodt U S P 1/4 pound can (blue label)	19	8	10	17	1 + 1 (no record) uneven at first periods shallow breathing and dusky color—atelectasis (nervous)	0
Mallinckrodt U S P bulk	63	16	47	3	3 + 1 (anesthetic chloroform ether ethyl chloride mixture) 1 respirations shallow 1 uneven dusky color 1 uneven (large amount 120 cc from 9 to 10 to 11 50 removal of tonsils and adenoids)	2 + 1 (no report) 1 uneven coughing tendency to vomit 1 induction difficult 1 coughing spasm cyanosis 1 induction difficult carbon dioxide oxygen ethyl chloride 1 coughing and suffocation
Merek for anesthesia 1/4 pound can	1		1	1		
Squibb 1/4 pound can	11	6	5	4	1 uneven induction suffocation (210 cc used)	0 5 uneven coughing anesthetic—chloroform ether ethyl chloride mixture 1 uneven anesthetic—chloroform ether ethyl chloride mixture
Totals	143			116	0	18

We are indebted to the surgical and nursing staffs of the University Hospital and the Syracuse Memorial Hospital for their cooperation during these tests.

The results show that bulk ether was satisfactory in 84.1 per cent, and quarter pound cans of ether in 78.7 per cent, any advantage shown being in favor of bulk ether. These results are confirmatory of the recent results of Hediger and Gold.²

No unusual complications were observed. There was one case of postanesthetic massive collapse of the lung (atelectasis). Reference to the table shows that not drum ether but U S P quarter pound can ether was employed in this case. No significance is attached to this happening, since it occurs about as often during intraspinal as during inhalation anesthesia and is apparently due, in both types to very shallow breathing.

From these results it seems evident that small can special ethers at a high cost offer no advantages over bulk ether U S P either in safety or in efficiency.

THE FOUNDATIONS OF DIET THERAPY

CLINICAL LECTURE AT ATLANTIC CITY SESSION

L. H. NEWBURGH, M.D.

ANN ARBOR, MICH.

Unlike the machine, the activity of the living organism is regulated from within. Its metabolism from hour to hour and from day to day proceeds in a manner largely independent of the supply of nutritive materials. Because of this inherent quality of the organism, its structure is injured when it is unable to obtain materials at the rate at which they are utilized or excreted. It may also be harmed when the intake of certain materials is excessive. But the degree of injury and the rate of its development vary greatly with the type of deprivation or excess.

It is a matter of only half a century since the importance of this point of view began to be realized. Then abruptly under the leadership of Carl Voit there was initiated a detailed study of the dietary requirements of the normal adult. Even though the problem is complicated, the knowledge already at hand is sufficient to inform us of most of the minimal requirements of the normal adult. In the case of the child much less has been established. Here an additional complexity is introduced by the necessity to provide for the formation of new tissue of ideal composition at an ideal rate. More recently realization has come that the diet of the pregnant woman, because of its effect on the fetus, needs a most careful consideration. During the first year the infant grows so rapidly that it cannot absorb from its digestive tract enough of the essential materials to produce new tissues of normal composition. As an example, certain facts concerning the growth of bone of small infants may be used, since they illustrate so vividly the dependence of normal skeletal development on the supply of calcium and phosphorus available to the fetus. At birth the bones of full term infants are filled with trabeculae. These trabeculae are absent from the bones of premature infants. Bauer and Aub,¹ working with kittens, observed the rapid disappearance of the trabeculae during the first weeks of extra-uterine life. McCollum and Simmonds report on experience from the Children's Hospital in Vienna, which leaves no doubt concerning the importance of the fetal store of calcium. Two full term infants were born on the same day, the first one of a healthy mother, the second of a woman whose bones were osteoporotic. Both infants were nursed by the healthy mother and each was given supplementary feedings of the same amount of cow's milk. Nevertheless, the infant of the woman who had received too little calcium during pregnancy developed severe rickets within six months while the other infant remained well. Nor does the inclusion of vitamin D in the diet guarantee normal growth of bone. Shohl² has given a clear demonstration of this fact. He writes "Rats on a normal diet retained about

From the Department of Internal Medicine University of Michigan Medical School.

Read before the General Scientific Meeting at the Eighty-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., June 11, 1935.

three times as much calcium and five times as much phosphorus as those on rachitogenic diets. This was true whether vitamin D was administered or not. The absolute amounts retained are dependent primarily upon the amounts in the diet.³

I hope that these few experiences give a conception of the goal sought by those workers who are striving to delineate the normal diet. Familiarity with the many facts already accumulated must be obtained by use of appropriate textbooks.²

But dietetics did not develop against such a background. The idea that disease could be ameliorated by forbidding the use of certain foods was acceptable to the physician from the earliest times. He unconcernedly omitted one food after another wholly oblivious of a far more important fact, namely, that the sick man should receive a sufficient amount of each of those substances which every normal person must have to avoid disease. The first requirement for the physician who proposes to employ diet therapy is a familiarity with the needs of the normal organism. In no other way can he assure himself that he is not producing a new disability or retarding recovery from the original one.

Next he must ask himself a second searching question. Does the disease under consideration make it necessary to increase or decrease the quantities of any of the constituents of the normal diet. For example, hyperthyroidism and fevers increase the expenditure of energy. The diet should accordingly contain increased amounts of fats and carbohydrates. Because of curtailment of activity, certain disabling diseases such as cardiac failure, act in the opposite direction. The work of the heart is proportional to the total metabolism. Therefore a sharp reduction of the energy value of the diet will lower the metabolic rate significantly. The burden on the incompetent heart may thus be lightened.

The diabetic patient can oxidize less dextrose than the normal person. In an effort to bring the dietary carbohydrate within the patient's capacity the error recently witnessed should not be repeated. A boy, aged 6 years, was brought to me because he was stunted, weak and irritable even though the urine was continuously free of sugar. The physician who had been in charge of the diet for several years had omitted all milk, because it contains sugar. In so doing he had also deprived the child of his chief source of calcium without making any other provision for the growth of bone. Rearrangement of the diet to include a pint of milk daily quickly caused a most gratifying improvement in the boy's general condition.

Students of nutrition have obtained much information concerning the requirement of protein, vitamins and inorganic salts, but it is often forgotten that water must be included among the essential dietary constituents. In the case of the normal individual one may usually rely on thirst to insure a sufficient intake, but in many abnormal states the physician either has curtailed the amount that the patient would otherwise drink or has failed to supply what the patient could not drink because of his disability. Such a restriction might have jeopardized even the health of a normal man.

Since no systematic study of water requirements had been made, my associates and I undertook such an

investigation. Some of our observations will be reported, because they are in sharp conflict with present beliefs.

In order to appreciate the water requirements of the human body, the physician must acquire some familiarity with the quantitative aspects of the loss of water. It is often forgotten that water vapor is continuously passing away from the skin and lungs as one means of carrying off the heat produced by the oxidative processes of the body. The normal adult of quiet occupation, living in a comfortable atmosphere, will lose from 900 to 1,400 Gm of water in that way each twenty-four hours. Either hot weather or muscular work may double or treble the output. The combination of the two, when the temperature is over 100 F and the air is dry, is sufficient to cause the evaporation of 10 liters of water a day. The other important loss of water is as urine. One of the major functions of the kidneys is to excrete in solution the solid end products of the metabolism. But the kidneys are sharply limited as to the amount of these products which they can excrete per unit of water. (This capacity may be expressed as the specific gravity of the urine, which in the case of healthy kidneys rises to 1.030 when the intake of fluid is sharply limited.) Appropriate studies⁴ have shown that normal kidneys need at least 500 Gm of water each twenty-four hours in order to eliminate the usual solid wastes of the period. When the water vapor is added to the urinary output and a small additional allowance is made for feces, it is seen that the normal man loses upward of 1,500 Gm of water daily. What will happen if his total intake of fluid is restricted to half that amount? Such studies⁵ have demonstrated that the loss by evaporation has a prior claim over the kidneys. The former is not lessened even though the water left over for the formation of urine is inadequate to prevent retention of wastes. The degree of the retention is, however, mitigated through a limited contribution of water by the body itself. Normal persons were subjected to the restricted intake of fluid for three or four days. During that interval the body grudgingly gave up from 3 to 4 liters of its own water. Then the symptoms of dehydration had become so disturbing that the experiments had to be stopped. Such observations have impressed us with the grave import of dehydration.

This minimal normal requirement of 1,500 Gm of water every twenty-four hours may be far too little to supply the demands of several pathologic states. None is more significant than nephritis, for diseased kidneys suffer a diminishing ability to form concentrated urine. In advanced stages of chronic nephritis it may take three times the normal amount of water to remove each gram of urinary solid. Under these circumstances the minimal intake that will prevent retention and dehydration is 2,500 Gm of water daily. Nevertheless the restriction of fluids in the management of nephritis is a widely spread practice based on the erroneous belief that diseased kidneys have difficulty in excreting water. In fact, it has been almost universally taught that blockage in the kidneys is the cause of nephritic edema. According to that doctrine, to get rid of the edema one must remove the water by other routes and at the same time one must permit as little water as possible to enter the body. Only a few simple experiments were needed

³ The book recently published by the author in collaboration with Frances Mackinnon (*The Practice of Dietetics* New York: Macmillan Company 1934) was designed to meet the practitioner's needs in this respect.

to show the utter fallacy of these earlier beliefs and to indicate the shocking amount of harm that their acceptance had worked

Examination of the accompanying table shows that the kidneys of the edematous subject were able to secrete a very large amount of urine containing a normal amount of solids as soon as he was permitted to drink a sufficient amount of water. The failure to

Water Requirements of Nephritic Patients

Subjects	Water Restricted for 24 Hours		Water as Desired for 24 Hours	
	Water In Urine Gm	Solids In Urine, Gm	Water In Urine Gm	Solids In Urine Gm
Normal	500	35	577	37
Nonedematous hypertensive nephritis	1,804	33	4,922	38
Edematous chronic nephritis	210	12	3,948	35

prevent retention on the preceding day could have been due only to insufficient water. Had he been able to mobilize body water on the day of restriction as the nonedematous nephritic patient did, he would have been able to avoid serious retention but at the expense of dehydration. One hesitates to make a choice between the two evils.

The recent studies of Maddock⁶ in a totally different field also emphasize the necessity of getting a sufficient amount of water into the bodies of certain patients. He writes:

A consideration of the sources of water and all the channels of its excretion is of incalculable value to the surgeon. Many diseases under his care are complicated by an interference with the normal intake of fluids and by abnormal outputs. Under these circumstances an adequate supply of water must be secured by parenteral administration. The problem is to know how much is needed. The administration of what seems to be a large amount may nevertheless fall far short of the needs, as the following experience illustrates. A youth entered the hospital with acute intestinal obstruction. Four hours later a colostomy was done. For several days after the operation he had rather persistent vomiting, watery diarrhea and moderate drainage from the colostomy tube. In order to meet these losses of fluid he had been given 3,500 cc. of fluid intravenously every day. However, in a few days the volume of urine had fallen to 250 cc per twenty-four hours. He was drowsy and the nonprotein nitrogen of the blood had risen to 57 mg per cent. A calculation of all the losses of water from the body was then made and it was found that the total amounted to about 4,500 cc each twenty-four hours. He had been dehydrating at the rate of 1,000 cc daily. The administration of sufficiently large volumes of fluid caused a rapid disappearance of symptoms, a great increase in the amount of urine and a return to normal of the blood N P N.

The diminishing output of urine was direct evidence of the inadequacy of the supply of water.

When man is studied as a mechanism he is found to obey the fundamental laws that govern the universe. His response to the energy of his environment is in no way different from that of an inanimate object. However, the physician appears to be less familiar with the significance of this relationship than with many other fields of nutrition. This is strange, because the transformation and expenditure of energy by mammals was the first phase of nutrition to be searchingly investigated. The great master Max Rubner built a solid

foundation for all subsequent studies of energy relations by demonstrating that the first law of thermodynamics, namely, that energy can neither be destroyed nor created, holds as rigidly for mammals as it does for the physical universe. This first principle may be recast into more familiar language by stating that all the energy released by the oxidations within the body will be dissipated at the rate at which it is produced, provided the internal temperature does not change. With the calorimeter this fundamental fact has been repeatedly confirmed and greatly elaborated in New York by Lusk and his pupils and in Boston by F. G. Benedict. Unfamiliarity with these fundamental laws has made the physician more willing to accept vitalistic explanations of disease. There could not have been the widespread acceptance of the contentions of several German professors if it had been generally known that man is an integral part of the universe and constrained to obey its basic laws. These men stated that there were two kinds of fat people: a small group that had become obese by merely eating too much, and a larger group of persons who were supposed to have laid down an increasing amount of adipose tissue without regard to what they had eaten. The latter statement was a flat denial of the law dealing with the conservation of energy. Attempts of many sorts were made to overcome this primary difficulty by offering bizarre and complicated metabolic abnormalities as causes of the adiposity. One such claim that has given satisfaction to many minds postulates that the fat man converts too much of the food to adipose tissue. Let us examine this statement. It is assumed that an obese individual of that hypothetical type who is not overfed receives daily 150 Gm of protein, 100 Gm of fat and 500 Gm of carbohydrate, making a total of 3,500 calories. The protein is utilized and thus yields 600 of the 3,500 calories expended. All the fat is deposited and all the carbohydrate is converted to fat and deposited. The total deposition of fat will then be the sum of the food fat (100 Gm) plus the fat derived from the carbohydrates (222 Gm), or 322 Gm. The subject will in that way have added 322 Gm daily to his weight. But, having stored the major portion of his diet, whence will he derive the 2,900 calories that he dissipated in addition to those afforded by the oxidation of protein? There can be only one answer: by oxidizing 322 Gm of body fat.

It seems to me that these false prophets made their mistake by paying too little heed to the self-regulatory nature of the living organism. They never recorded the total expenditure of energy of the individual under observation. They fed him a known amount of food and compared its calorific value with what they guessed he was expending. If he did not lose weight according to the expectation, it was assumed that he was the victim of some peculiar disease that made it possible for him to evade the laws that govern normal persons and the universe in general.

When, however, we had devised a technic⁷ that permitted us to record the expenditure of energy over long periods of time, we were gratified to find that the earlier conclusions concerning the energy relations of normal men applied in detail to all obese persons. There is but one fundamental cause⁸ of obesity. It is an inflow of energy that exceeds the outflow. The

outflow may be large or small. If the latter, a small amount of food may still contain as much energy as that expended by the patient. All adiposity can be reduced by a properly constituted diet.

SUMMARY

This paper consists of a plea to put diet therapy on a rational basis. Attempts to alleviate disease by manipulation of the intake of food are as old as medicine itself, but systematic efforts to discover the nutritional needs of man are very modern. In the absence of this new knowledge, the physician accomplished little through diet because he centered his attention on the omission of foods. He is urged to acquaint himself with the quality and quantity of the constituents of the normal diet. This is his only assurance that he will not prescribe for his patient a diet that is deficient in any respect. He must then decide whether the condition of the patient requires an increase or a decrease of any one or several of the dietary constituents so that he may modify the normal diet to meet the new requirements.

PAUL NICHOLAS LEECH, Secretary

SHOTGUN VITAMIN THERAPY

The American people have been made "vitamin-conscious." Clever advertising emphasis on the infinitesimal and not easily detectable amounts in which the vitamins occur in ordinary foodstuffs and further play on the startling results that appear in animals deprived of even these small amounts have stimulated a popular romance and mystery.

This popularization of the comparatively recently acquired and constantly growing knowledge of the various vitamins has resulted in many errors and misconceptions, largely to the benefit of the unscrupulous but sometimes also of the well intentioned manufacturers of products offered to the public. Among these misconceptions are the ideas that everybody needs to take supplements of all the vitamins all the time and that it is both therapeutically and chemically advisable to combine all or some of the vitamins, perhaps with some mineral or minerals, in one preparation. It has apparently been forgotten that no necessity has been found for administering preparations containing complex combinations for effective maintenance of health when a well balanced diet is taken. Clinically recognizable multiple vitamin deficiency diseases are certainly rare in this country.

It has been stated that about thirty-seven elements or substances are necessary in a complete diet; among these are vitamins. That they are grouped together under this name does not indicate that they are closely related chemically. For instance, vitamin C is closely related to the sugars while vitamin D is one of the sterols. From a physiologic standpoint it is just as irrational to prescribe a mixture of a number of the vitamins as a combination consisting of cystine, iodine, iron, and linoleic acid or any other combination of dietary essentials.

At the present time there seems to be no more logical basis for including all or a number of vitamins in one preparation than there is for combining a number of the other known dietary essentials in any one pharmaceutical product. The functions of the vitamins are as diverse and independent as their chemical constitution would indicate.

It is not perhaps surprising that efforts have been made to supplant the use of the various natural vitamin containing substances by preparations of highly potent concentrates either

singly or in combination, and also by their combination with minerals in mixtures, in tablets and in capsules. Having prepared such combinations, it is of course natural that manufacturers propagandize information regarding their need extensively to the medical profession through scientific journals and also to the lay world through the radio, the press and the mails. At first sight the combinations of vitamins offer the obvious advantage of simplicity of administration from the point of view of both the patient and the physician. From the standpoint of the manufacturing pharmacists they have the added advantage of ease of preparation, wide demand and ready marketability.

The fact that the vitamins are chemically active substances essential in all probability, for maintaining normal cell metabolism makes it necessary here to consider the bearing of the pharmacologic incompatibility of mixtures of drugs and their possible antagonistic action in the body. Sufficient attention perhaps has not been paid to the physiologic action of potent vitamin concentrates when they are combined and taken by man into the body in fixed amounts, that is, as to whether the action is the same as when the vitamins in their natural state are supplied to the organism, or whether it is different.

The voluminous literature reveals little information dealing directly with the subject of polypharmaceutic mixtures of vitamins. A few studies in which a combination of physiologically active concentrates has been administered indicate significant interactions between the vitamins and fail to show the anticipated beneficial results. There should be borne in mind the paucity of information in this field, and firms marketing such products should be reminded that the burden of proof for claims made for such mixtures rests entirely on the firms making them.

The question arises as to whether there may be an enhancing action of one vitamin concentrate when combined with another. There is practically no reference in the literature to such a phenomenon when the absence of a multiple deficiency disease is excluded critically. The impression is gained that, at best, the action of combined concentrates of vitamins would be the sum of the effects of each vitamin constituent. Commonly, the potency used of each concentrate for prophylaxis is that which has been adopted as the protective amount which, it should be remembered, has been determined according to its effect in different species of animals. The argument that certain vitamins exist together in nature is no guaranty that the action to be expected from these is brought about by administration of potent concentrates in which they are combined by various processes. When a specific vitamin in its natural state is administered, utilization in the normal human body is adjusted according to a nicely regulated mechanism, but when the vitamins are extracted or concentrated and given together in different mixtures in tablets and in capsules, it may be questioned whether or not there is an interference or enhancement of the specific effect of the different vitamin concentrates so combined. So far as can be found there is in the literature very little reference to that question.

Even if no harm results, it should not be forgotten that the giving of combined vitamin concentrates unnecessarily often proves to be an economic wastage. This is so especially in the use of such combinations in the treatment of a specific deficiency disease, when the better practice of medicine indicates the therapeutic use of the specific or of a single vitamin in adequate dosage without necessarily requiring an increase (or decrease) in dosage of the other vitamins. There is no direct evidence that vitamins have a supplemental effect on one another when in combination. It should be pointed out here that the administration of complex vitamin preparations is open to all of the objections that may be urged against the routine use of mixtures containing ingredients in fixed proportions.

It is well known that the commonly used vitamins are peculiarly susceptible to destructive effects when they are removed from their natural chemical environment, it does not therefore seem necessary to discuss in any detail the antagonistic action of the different factors in the destruction of each individual vitamin. Yet there are certain pertinent facts that may be of interest.

For instance, it has been shown that there is impairment in potencies of vitamins A and E when they are subjected to

aeration, especially in the presence of heat. As early as 1920, Hopkins showed that vitamin A in butter, although resistant to heat alone, is rapidly destroyed by heat plus aeration. Later, Mattill discovered that not only oxidation but rancidity developing in sources of vitamins A and E destroyed their specific action. Another procedure that decreases the availability and hence the effectiveness of vitamins A and E is admixture of mineral oil. Presumably this results from the solvent action of the oil, so that the vitamins escape absorption. The ease with which vitamin C potency is impaired by heat and by varying the pH of the solution in which it is contained has been repeatedly observed and is of practical significance in the canning of fruits and vegetables. The catalytic action of copper in such processing is well established as responsible for destruction of vitamin C.

Further evidences of the lessening of the potency of vitamin concentrates in mixtures are found in their combination with minerals. The references consulted are those concerned chiefly with iron, but there is some reason to suppose that iodine may destroy the potency of vitamins. McCollum was the first to note the destructive effect on vitamin A of diets containing iron salts, when fed to white rats. Subsequently, Jones showed that ferrous sulphate could so effectively destroy vitamin A that xerophthalmia might be produced (in rats). Mattill and also Waddell and Steenbock reported that vitamin E could be destroyed by the addition of iron salt to a stock ration.

It appears, therefore, that within recent years the contributing causes for the destruction or prevention of the characteristic effects of vitamins have received much attention, with the result that special efforts have been made in manufacturing such preparations to make them effective. In the case of some preparations this has been found possible. The use of antioxidants, the regulation of the pH and of the thermal conditions, and various other measures have been designed to aid in preventing the destructive action. It may be said that vitamin concentrates of vitamins A and D can be manufactured so that in the finished product the concentrate will meet the requirements of the recent U S P X-revised dosages for these vitamins. But it is very difficult to find any evidence whatever that a deterioration of the potency may not take place on standing or from the interaction of highly potent concentrates of other vitamins when combined. This holds true for combinations of vitamin concentrates in the form of capsules, in tablets and in liquid or oily mixtures, and of vitamin concentrates with minerals. Tablets and concentrates containing vitamins A and D have been quite stable for the period of years in which it has been possible to test them by biologic assay.

There is experimental evidence supporting the view that an antagonistic reaction exists between certain of the vitamins when given in combination. Certain investigators have advanced the belief that large amounts of vitamin A concentrate may be responsible for a disturbing effect on vitamin B. As early as 1922 it was reported by Mouriquand and Michel that, in a series of experiments on the interference with the curative action of vitamin C in the treatment of scurvy, they attributed the interference to the presence of vitamin A.

The Council's referee recently reviewed a considerable number of cases of scurvy occurring in an eastern hospital where there was practically an epidemic of scurvy. Nearly every year from forty to sixty children with scurvy are seen. Reviewing the number of cases in his service in the last ten years, the referee found something like 300 or 400. When asked, some of the mothers stated that their children had been fed orange juice. When asked how the orange juice was given, they stated that it had been mixed with cod liver oil preparations.

There have been numerous investigations on the toxicity of vitamin D concentrates in large quantities. A few of these are the investigations of Kreitmar and Moll, Pfannenstiel, Light, Miller and Frev, and Klein. In such experiments the addition of extra amounts of vitamin B complex has been shown to diminish the toxicity of excessive vitamin D dosage according to the work of Harris and Moore.

These are some of the better known examples of the interrelationship of the total quantities of vitamins to one another. It certainly would seem that one vitamin in varying propor-

tions, might render ineffective quantities of another vitamin that normally are adequate. Further investigation seems necessary before one is able to say just which vitamin concentrates may be safely mixed without impairment of the activity of the ingredients, how much of each is necessary in such mixtures, and what deleterious influences may result from the presence in such mixtures of various oils, oxidizing agents, mineral salts, and so on.

From this relatively short review concerning the combination of vitamin concentrates for prophylaxis and therapeutic effects, certain points stand out.

It has been brought out that there has been practically no experimental or clinical evidence which tends to show that vitamin concentrates are enhanced or have any supplementary action when given in combination, either for prophylaxis or for therapeutics. The best that may be expected from any given combination is that each specific vitamin will produce its maximum effect independently of the other ingredients of the mixture.

It has also been shown that certain inorganic, organic and even physical agents may destroy the potency of vitamins with which they come in contact. For example, vitamins A and E, especially the former, are destroyed by contact with oxygen, especially during heating, by mixture with mineral salts like iron, and with certain organic fats. Even food materials and certain inert substances may interfere with the effect of or absorption of vitamins. For example, lard and other unsaturated food fats and mineral oil so affect vitamin A. This makes it important to study further the influence of other ingredients in synthetic preparations of vitamins where they have been removed from the protective influences present in their natural sources, and to investigate the results of administering vitamin concentrates in close relation to food intake. The presence of pathologic states may also influence the absorption of vitamins given even in ordinarily adequate amounts, that is, abnormalities in the small intestine or operative shunts may interfere with the absorption of vitamins A, D and B, biliary disease may likewise interfere with vitamin A utilization, and gastric anacidity may prevent the proper utilization of vitamins C and B.

It has been pointed out that there is ever increasing evidence that a delicate interrelationship exists between vitamins, because of either a physiologic relationship or actual incompatibilities of various vitamins, that the administration in combination of concentrates of vitamins, each of which is active independently, may so alter the effectiveness of each as to render it inadequate or to necessitate an increase in its dosage. For example, vitamin B has been reported to be rendered less effective when given with large amounts of vitamin A. In order to offset that, it seems that much larger amounts of vitamin B complex are necessary in such mixtures. In the case of vitamin C, large quantities of cod liver oil may render it ineffective in the prevention and cure of scurvy. There is not even a sound empirical basis for fixing the relative ratios of the various vitamin ingredients of mixtures.

The attempt to supply a sufficient amount of a single vitamin concentrate specifically indicated, when a mixture of vitamins is prescribed, may result in an excess of the remaining active agents. The possibility of harm from such excess must be kept in mind, even when no harm is done, such a combination may constitute an economic waste.

From this review the Council concluded that there is a wide field for the study of this question as to the incompatibilities, the impairment of vitamins when they are prepared in concentrate and prepared in mixtures, and as to the manner in which they are administered to the patient.

One of the cardinal principles of the Council has always been that the burden of proof lies with the manufacturer. From the foregoing brief review it is discerned easily that the status of mixed vitamin therapy is on insecure grounds. The Council therefore will not accept mixtures containing vitamin concentrates until the manufacturers are able to present adequate evidence of their rationality. This does not refer, however, to concentrates of vitamin A and D, which occur combined in nature as such in cod liver oil, nor does it apply to any combinations of vitamins that may occur in nature in therapeutic amounts.

CELLU BLACKBERRIES PACKED IN WATER WITHOUT ADDED SUGAR OR SALT

Distributor—The Chicago Dietetic Supply House Inc, Chicago

Packer—Eugene Fruit Growers Association Eugene, Ore

Description—Canned cooked blackberries packed in water without added sugar or salt

Manufacture—Blackberries picked at the proper stage of ripeness are mechanically graded according to size (imperfect fruit or foreign material is removed), spray-washed and automatically filled into cans. The berries are covered with water heated for a definite time at 91 C, and the cans are sealed and processed at 100 C. and cooled

Analysis (submitted by distributor) —

per cent

Moisture	89.0
Total solids	11.0
Ash	0.4
Fat (ether extract)	0.8
Protein (N x 6.25)	1.0
Reducing sugars as invert sugar	4.6
Sucrose	0.2
Crude fiber	2.0
Carbohydrates other than crude fiber (by difference)	6.8

Calories—0.4 per gram 11 per ounce

Claims of Distributor—For diets in which sweetened fruit is proscribed

MONARCH STRAINED APPLESAUCE, CARROTS, PEAS, PRUNES FLAVORED WITH LEMON JUICE, SPINACH, STRINGLESS BEANS AND VEGETABLE SOUP WITH CEREAL AND BEEF BROTH UNSEASONED

Distributor—Reid, Murdoch & Company, Chicago

Packer—The Larsen Company, Green Bay, Wis

Description—Respectively strained applesauce, carrots, peas, prunes flavored with lemon juice, spinach, stringless beans and vegetable soup (carrots, potatoes, tomatoes, celery, peas, beans, spinach) with pearl barley and beef extract prepared by efficient methods for retention in high degree of the natural mineral and vitamin values. No added sugar or salt. These products are the same as the respective accepted Larsen's vegetables and fruits (THE JOURNAL, July 22, 1933, p 282, July 29, 1933, p 366, Aug 12, 1933, p 525, Aug 19, 1933, p 605, Aug 26, 1933, p 675, Aug 10, 1935, p 437)

(1) BLUE AND WHITE BRAND CRYSTAL WHITE TABLE SYRUP

(2) BLUE AND WHITE BRAND GOLDEN TABLE SYRUP

Distributor—Red and White Corporation Chicago

Packers—Manufacturers of accepted brands of syrups

Description—(1) Table syrup, corn syrup with cane sugar syrup, plum or flavored with vanilla or with vanilla and coumarin (THE JOURNAL, Oct 15, 1932, p 1353, Sept 3, 1932, p 833, Nov 18, 1933, p 1635, and April 15, 1933, p 1174). (2) Table syrup, corn syrup flavored with refiners' syrup (THE JOURNAL, Dec. 3, 1932, p 1948, July 23, 1932, p 309, Oct 28, 1933, p 1393, and March 5, 1932, p 817)

CHIPPEWA IODIZED SALT

Manufacturer—The Ohio Salt Company, Wadsworth, Ohio

Description—Table salt containing added magnesium carbonate, sodium bicarbonate and potassium iodide (0.02 per cent)

Manufacture—Salt containing 1 per cent magnesium carbonate prepared as described for Chippewa Free Running Salt (THE JOURNAL, Sept 7, 1935, p 800), is admixed with potassium iodide and a small quantity of sodium bicarbonate and automatically packed

Analysis (submitted by manufacturer) —

Moisture	trace
Calcium sulphate	0.7
Calcium chloride	0.08
Magnesium carbonate	1.0
Potassium iodide	0.02
Sodium bicarbonate	0.1
Sodium chloride (by difference)	98.2

Claims of Manufacturer—For all table and cooking uses. The added magnesium carbonate tends to preserve free running qualities and the sodium bicarbonate to prevent loss of iodine. The iodine in the salt aids in preventing simple goiter caused by insufficient iodine in the diet. Used daily as the only salt on the table and in cooking, it richly supplements the iodine of diets deficient in that element and thus helps to protect against simple goiter

SIEVED APPLES, APRICOTS, ASPARAGUS, BEETS, CARROTS, CELERY, GREEN BEANS, PEACHES, PEAS, PRUNES, SPINACH, TOMATOES

UNSEASONED

- (1) IRIS BRAND
- (2) SEAKIST
- (3) TRUPAK
- (4) WELLMAN BRAND

Distributors—(1) Haas, Baruch & Co, Los Angeles, (2) The Nielsen Corp Ltd, San Francisco, (3) Haas Brothers, San Francisco, Oakland, Fresno, (4) Wellman Peck & Co, San Francisco

Packer—The Nielsen Corp Ltd, Oakland, Calif

Description—Respectively sieved apples, apricots, asparagus, beets, carrots, celery, green beans, peaches, peas, prunes, spinach and tomatoes prepared by efficient methods for retention in high degree of the natural mineral and vitamin values. No added sugar or salt. The products are the same as the respective accepted Warranty vegetables and fruits (THE JOURNAL, May 11, 1935, p 1708, March 9, 1935, p 835, April 27, 1935, p 1504, April 13, 1935, p 1331, March 16, 1935, p 923, March 9, 1935, p 835, April 6, 1935, p 1241, March 23, 1935, p 1007, April 20, 1935, p 1419, March 30, 1935, p 1074, Feb 2, 1935, p 399, June 1, 1935, p 1999)

FAIRWAY WHEAT CEREAL

Distributor—Twin City Wholesale Grocer Company, St Paul

Manufacturer—Pillsbury Flour Mills Company, Minneapolis

Description—Granular wheat endosperm or farina, practically free of germ and bran.

Manufacture—Wheat is cleaned, washed, scoured, crushed, and the bran and germ separated from the flour middlings (endosperm) by the usual milling methods. Endosperm graded to uniform granulation is heated to destroy any insect infestation and packed in cartons

Analysis (submitted by distributor) —

SATURDAY, SEPTEMBER 28, 1935

THE VITAMIN ALPHABET

In 1911 Funk proposed the term "beriberi vitamin" for the active substance the lack of which in the diet led to polyneuritis. Subsequently the designation "vitamin" (later contracted to "vitamin") was employed for an ever growing group of principles of unknown chemical constitution occurring in the diet and necessary to health or, ultimately, to life. In order to avoid difficulties in the nomenclature of these dietary factors, which became associated more or less fortuitously, McCollum suggested that alphabetical designations be employed for them until such time as chemical names could be assigned. Drummond in 1920 combined the terms of Funk and McCollum,¹ since then "vitamin A, B, C" and so on have been used almost uniformly in the literature, though not always to designate the same substances.

It appears that, owing to popularization of the terms, the use of the alphabetical designations of McCollum has persisted in some cases at least beyond the time intended by their originator. Moldavan² has recently pointed out

The crystallization, the isolation and our more or less definite knowledge of the physiological properties of the so-called vitamins show that there is no longer any scientific basis to maintain such widely different chemical substances as carotenes, ascorbic [cevitamic] acid, irradiated sterols, pyrimidine-thiazole compounds, sodium phosphate, manganese compounds, etc. under the same heading, except perhaps for historical purposes.

The academical disagreement between British and American biologists over mere initials to be given to otherwise well-defined products adds to the confusion.

Antineuritic, antiscorbutic, antirachitic, antianemic, anti-goitric, etc., substances should be classified with the chemical family to which they belong or grouped with the natural or pharmaceutical substances which have closely related physiological properties.

This is in accord with the conclusions of the Council on Pharmacy and Chemistry, whose report on "Shotgun Vitamin Therapy"³ appears elsewhere in this issue. The association of a number of unrelated essential dietary factors under one name has had several unde-

sirable results, particularly in therapeutics. For no other reason than that they are grouped under one name, various vitamins, even those that do not occur together in natural sources, have been administered in pharmaceutical combination. Mixtures containing almost every conceivable combination of vitamins, some including also other real or alleged dietary essentials, have been offered to the medical profession by drug manufacturers. As the Council points out, "From a physiologic standpoint, it is just as irrational to prescribe a mixture of a number of the vitamins as a combination consisting of cystine, iodine, iron, and linoleic acid or any other combination of dietary essentials."

The functions of the vitamins are as diverse and independent as their chemical constitution would indicate. The Council discusses evidence relating to chemical and biologic incompatibility of different vitamins. It emphasizes the necessity of considering concentrated preparations of these agents in the same light as drugs, "the administration of complex vitamin preparations is open to all of the objections that may be urged against the routine use of mixtures containing ingredients in fixed proportions." With increasing knowledge of the nature and effects of the substances that have been grouped as "vitamins" the necessity for a more rational approach to their therapeutic use becomes evident.

REX BEACH WRITES UP BONINE

Rex Beach's promotion of the claims for Mahlon Locke in the *Cosmopolitan* magazine must have sold a good many copies. It may even have had something to do with the large display advertisement of M. W. Locke shoes that appeared in the same issue as one of the Rex Beach ballyhoos for the toe-twister of Williamsburg. Nobody knows how many sick people it caused to waste considerable sums of money traveling to the Locke shrine for the kind of faith healing that Locke employs. But that apparently does not worry Rex Beach! It is his business to write articles that he can sell, he seems to be little, if at all, concerned with the public health aspects of the matter.

Cosmopolitan magazine now announces in association with the publishing of Mr. Beach's latest article that "This article reflects the impressions of the author, and we publish it for its human interest value and not as carrying an endorsement." This announcement appears in very small type and, doubtless, will not make nearly as much of an impression on the readers as the display type and the pictures that accompany Mr. Beach's exposition of the qualities of Dr. F. N. Bonine as a "famous benefactor of the blind" and a "Modern Miracle Man."

The record of Dr. F. N. Bonine in the field of medicine can be recounted in a few short lines. He graduated from the University of Michigan in 1886 and received his license to practice medicine in Michigan in 1900. He seems to have been practicing continuously

¹ Cited from Sherman and Smith: *The Vitamins*. New York: Chemical Catalog Company, Inc., 1931.

² Moldavan: *Andrew's Vitamins*, Science 81: 639 (June 28) 1935.

³ *Shotgun Vitamin Therapy*, report of the Council on Pharmacy and Chemistry, this issue, p. 1037.

in Niles, Mich., but did not become a member of his local medical society until 1927. He is not a Fellow of the American Medical Association nor is he a member of any national organization in the field of ophthalmology. Dr. Bonine does not advertise, but he has apparently for years been doing a large business under the claim of dissolving cataract. Patients who have been to Niles to see Dr. Bonine describe a typical experience which much resembles that associated with the practice of Mahlon Locke. Great numbers of people come to see him. They are charged \$2 for the first visit and \$1 for subsequent visits. The doctor practices in his shirt sleeves and the "miracles" are performed under circumstances which are calculated to impress by their simplicity. The usual method of treatment for patients with cataract is the prescription of eye drops which consist largely of boric acid and sodium salicylate in witch hazel water. There is not the slightest scientific basis for the claim that any cataract is benefited or removed by putting such drops in the eyes.

While Dr. Bonine does not advertise, he has certainly been no modest violet as far as concerns the use of publicity. His name has continuously been associated with the employees of the prize ring, the wrestlers, track athletes and similar inhabitants of the spotlight. In 1928 when he had pneumonia, there was a lot of furor associated with the shipment of a pneumonia serum by airplane. At that time a newspaper called the Benton Harbor *Palladium* said "Dr. Bonine is undoubtedly the World's greatest physician in the treatment and removal of eye cataracts. He uses a secret formula for which he has been offered a fortune by hospitals and physicians in private practice. Dr. Bonine is said to have declared that he will take with him to the grave this formula with which he has so successfully treated cataracts for the last quarter century. However, friends of his declare that when the Bonine strong box is opened and his will read, this safely guarded formula will be made known to the world."

This is just about the whole story in relationship to Dr. Fred N. Bonine. Every one knows that a patient with gradually developing cataract passes through phases in which he sees better simply because of his anxiety to improve and that cataracts vary greatly in the length of time required for them to mature or in the length of time in which eyesight is sufficiently lost to make surgical procedure necessary. The cataract may spontaneously regress, advance or remain quiescent. During this period of gradual development the hopeful patient is likely to claim improvement with any method of treatment given to him with a strong enough suggestion that it will be of benefit. Dr. Bonine is not the first physician to be misled into a belief of efficiency by this aspect of human nature. Yet eventually every scientifically minded man learns to distinguish between the conviction of the believer and the appearances seen with the ophthalmoscope and other

scientific devices that cannot be misled by the vagaries of the human mind.

Mr. Rex Beach and the *Cosmopolitan* are not rendering a service to mankind by their exploitation of so-called miracle men. They are likely to cause a considerable number of sick people to spend money for transportation which might very well be spent in securing good medical care at the hands of competent physicians. Mr. Beach is himself hardly sufficiently trained in scientific medicine to have the slightest comprehension of the significance of testimonials or of the enthusiastic utterances of neighbors and friends in the villages which depend on the "miracle men" for such business as comes to them.

Incidentally, Mr. Beach spent some time last June in the Scientific Exhibit of the American Medical Association in Atlantic City. What he saw there were actual miracles of science with the evidence to support them. Yet he did not choose to exploit these established discoveries, fearing perhaps that they lacked the romance associated with the fictional records of the "miracle workers" of whom he writes.

MEDICAL SERVICES UNDER WORKS PROGRESS ADMINISTRATION

The United States Works Progress Administration has announced that mutually satisfactory arrangements with medical groups and hospitals are now in process of formulation for the medical, surgical and hospital care of employees of the administration who are injured in the performance of their work. Under the provisions of the United States Employees' Compensation Act of 1916, as amended, such services must be furnished by or on the order of United States medical officers and hospitals, but when that is not practicable they may be furnished by or on the order of private physicians and hospitals designated or approved by the United States Employees' Compensation Commission. When no such physician or hospital is available, however, the proper local representative of the Works Progress Administration may approve physicians and hospitals to render necessary services. The term "physician" is construed by the United States Employees' Administration to include only graduates of recognized medical schools who hold the degree of doctor of medicine and are licensed to practice medicine in the states in which they reside.

Under the Works Progress Administration organization an accident compensation officer in each state is to be responsible for the entire conduct of the compensation program there. A state compensation office and such local compensation offices as may be necessary are to be established to facilitate the handling of claims. A deputy compensation officer, empowered to act locally for the state compensation officer, is to visit each compensation district at least once each week. Competent first aid men are to be on duty on each job undertaken by the administration.

Physicians and hospitals should submit their vouchers for services rendered to employees of the Works Progress Administration to the local compensation representative. In the case of employees of other federal establishments, vouchers should be submitted to the official superior of the injured employee. The local compensation representative or the official superior of the injured employee, as the case may be, is to see that the services rendered were properly authorized, that charges are itemized on the correct form and that the signatures on the voucher are proper. When the voucher is in proper form, he is to endorse it and transmit it to the United State Employees' Compensation Commission in Washington for payment.

Physicians should not submit vouchers direct to the United States Employees' Compensation Commission in Washington, since this will result in delay and expense owing to the necessary returning of such vouchers to local compensation representatives or official superiors of injured employees for endorsement.

BIOLOGIC PHOTOGRAPHY

Today the great advances in medical science seem to depend largely on the ingenuity of inventors who prolong and project the senses of mankind. It would almost seem as if the human brain and the human eye unaided could proceed no further in their accomplishments. By the use of the microscope, vision is magnified thousands of times, by the use of the telescope it is prolonged thousands of miles, by the use of the cystoscope, the ophthalmoscope and similar devices it is projected into cavities that were formerly dark and obscure. With the x-rays and the various dye substances and devices that have been developed auxiliary to the x-rays, organs and tissues within the body are made apparent. Diagnosis has been greatly facilitated and much that formerly was left to imagination and guesswork is now susceptible of actual measurement and permanent record.

In the development of records as well significant changes have occurred. In earlier times men made crude drawings of appearances which they wished to record permanently. Gradually medical art developed. The evolution of anatomic illustration, as described by Choulant, Frank, Garrison and many others, is one of the most interesting chapters in the history of medicine. Next came the use of photography for the making of permanent records, and, with the development of photography, colored illustrations, black and white motion pictures and colored motion pictures, which have successively been the focus of medical interest. Moreover, the possibilities of the use of illustrations in teaching have been extended by the development of the microscopic slide, the lantern slide, the stereoscopic illustration, the projectoscope, the bioscope and similar apparatus. By means of these devices medical teaching has been greatly facilitated. The future is sure to yield

a vast amount of improvement beyond the results already available.

Another significant aspect of medical illustration is the development of photography for medicolegal purposes. The patient who comes to a plastic surgeon for repair and remodeling of a nose, the pinning back of flapping ears or the removal of an unsightly scar is not likely to remember after the operative procedure his appearance previous to the operation. The wise physician makes permanent photographic records of the evolution in the patient's appearance, so that the results of his work are clearly apparent.

The importance of photography as a means of recording specimens both in the living and in the dead subject cannot be overestimated. Photographs are accurate, impressive and easily interpreted. A good picture with a few words of description gives the reader an idea of the conditions actually seen better than a whole page of descriptive matter, even when written by a master in the use of words.

So rapidly has the interest in these phases of medical recording developed that there has existed for a number of years an association devoted to improvement in the art and technic of this practice. At the annual session of the Association of Biologic Photographers, just held, the topics discussed included intragastric photography, infra-red photography, the development of the surgical motion picture, the miniature camera and microcinematography. Photographic apparatus has been used for recording extraordinary motions and for making available records of the actions of organs within the body. Among the extraordinarily varied number of technicians now available in the medical field, the expert in clinical photography has an accepted position. No doubt the future development of the large hospital, the institution for investigation and the institution for medicolegal study will include, as an economic and scientific necessity, suitable equipment and personnel in this field.

Current Comment

EFFECT OF VITAMIN D ON CALCIUM CONTENT OF DENTIN

Controlled clinical experiments seem to indicate that therapeutic doses of vitamin D will both prevent and arrest dental caries when the lesions produced are apparently due to vitamin D or calcium deficiency.¹ It is assumed in explanation that the vitamin will increase the calcium content of the dentin and that such an increased calcium content will prevent or arrest caries. In a recent report Fish² records an unsuccessful attempt to alter the calcium content of the dentin of dogs by giving heavy doses of vitamin D and calcium over a prolonged period of time.

1 Mellanby: May Diet and the Teeth. III. The Effect of Diet on Dental Structure and Disease in Man. Special Reprint Series. Medical Research Council 191. 1934.
2 Fish, E. W. The Effect of Vitamin D on the Calcium Content of the Dentin. J. Physiol. 84: 272 (June 18) 1935.

Three dogs from the same litter were used in his observations. Two teeth were excised from each animal at the beginning of the feeding experiment and the two symmetrically opposite teeth were removed at the end. A specimen of the dentin was prepared from each tooth and analyzed. Each specimen was freed mechanically from pulp tissue and from enamel and cementum and was prepared from the cervical part of the tooth. The pieces were dried at 105 C. for eighteen hours. This dry weight was therefore taken as a basis for calculation and the calcium content was expressed as the proportion of calcium oxide to this weight. The basic diet of raw meat hounds' meal and water was continued with all animals, but calcium and large doses of vitamin D for varying periods were added. This regimen almost doubled the normal calcium content of the blood. Roentgenograms showed marked increase in opacity of the bones but no apparent change in the teeth. The chemical analysis of the dentin gave no significant increase in calcium content as compared with the preexperimental period. Definite as are these results for the period of about seventy days in dogs the case against vitamin D cannot be considered definitely closed. The fact that a dog has a lower calcium content of dentin than man and that he is absolutely immune to dental caries raises the question as to whether the mechanisms involved are entirely similar physiologically. Doubt is thus thrown on the reliability of the fundamental assumption that caries is dependent on the calcium content of the dentin alone. Furthermore, caries is generally of slow development and it may be necessary to carry the crucial investigations over a period of years rather than of weeks.

INFANT MORTALITY IN NEW YORK A HUNDRED YEARS AGO

It has been generally assumed that the infant mortality rates must have been exceedingly high a hundred years ago and that a fairly continuous reduction has taken place since that time. Bolduan and Weiner¹ have recently attempted to determine the accuracy of that assumption when applied to New York City. The statistical data of that time are admittedly inaccurate and incomplete, but by the use of the so-called city inspectors' reports compiled regularly from the interment records of the various cemeteries it was found possible to approximate the number of infant deaths. Evidence exists also for believing that the birth rate at the time was about 40 per thousand. It was therefore possible to postulate statistics carrying a reasonable accuracy. A chart constructed from these statistics and extended by the more accurate recording of later years brings out the fact that from a relatively low infant mortality rate at the beginning of the nineteenth century the rate rose to a maximum during the sixties and that it thereafter declined. The evidence therefore indicates that in New York City the infant mortality rate at the beginning of the nineteenth century was probably no higher than it was at the opening of the present century. The factors affecting the rate were, of course, quite different at that time than at present.

¹ Bolduan, Charles, and Weiner, Louis. Infant Mortality in New York City One Hundred Years Ago. *J. Pediatr.* 7: 55 (July) 1935.

Association News

RADIO BROADCASTS

The American Medical Association will broadcast over the Blue network of the National Broadcasting Company at 5 p. m. eastern standard time (4 o'clock central standard time, 3 o'clock mountain time) October 1 and each Tuesday thereafter, presenting a dramatized program with incidental music under the general theme of "Medical Emergencies and How They Are Met." The title of the program will be "Your Health." The program will be recognizable by a musical salutation through which the voice of the announcer will offer a toast "Ladies and Gentlemen, Your Health!" The theme of the program will be repeated each week in the opening announcement, which informs the listener that the same medical knowledge and the same doctors that are mobilized for the meeting of grave medical emergencies are available in every community, day and night, for the promotion of the health of the people. Each program will include a brief talk dealing with the central theme of the individual broadcast.

The October schedule is as follows:

October 1	Burns, Morris Fishbein, M.D.
October 8	Hazards from Foreign Shores, W. W. Bauer, M.D.
October 15	Unconsciousness, Morris Fishbein, M.D.
October 22	Asphyxiation, W. W. Bauer, M.D.
October 29	Poisonous Plants and Insects, W. W. Bauer, M.D.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

CALIFORNIA

Hospital News—The San Diego Hospital, San Diego, has changed its name, effective September 15 to "Hoffman Memorial Hospital," to perpetuate the name of the man in whose honor the hospital was originally dedicated. There will be no change in management or personnel.—Dr. Edouard S. Loizeau has been appointed superintendent of the San Diego County General Hospital, San Diego, to succeed Dr. Charles E. Sisson.

Society News—Dr. Robert W. Meals, Los Angeles, discussed "Endocrinology from the General Practitioners' Standpoint" before the San Diego County Medical Society, San Diego, September 10.—At a meeting of the Alameda County Medical Association in Oakland, September 16, speakers included Drs. Homer W. Crane, Berkeley, and Herman V. Allington on "Spirillosis of the Lung" and "The Treatment of Acne Vulgaris," respectively.—Dr. Montague S. Woolf, San Francisco, addressed the Solano County Medical Society, September 10, in Vallejo, on "Commoner Diseases of the Anorectal Region and Their Treatment"—Dr. Lucius W. Johnson, captain, medical corps, U. S. Navy, discussed "Medicine and Surgery in the Fleet" before the Hollywood Academy of Medicine, September 19, and Dr. Paul E. Walker, assistant surgeon, U. S. Public Health Service "Relation of the U. S. Public Health Service to Immigration"—Dr. Arthur S. Granger, among others, addressed the Los Angeles Society of Ophthalmology and Otolaryngology, September 23, on "Oil Tumors of the Lungs Produced by Intratracheal Instillation."

CONNECTICUT

Personal—Dr. Edward J. Finn has been appointed health officer of Shelton, succeeding Dr. Francis I. Nettleton.—Dr. John D. Milburn has been named health officer of East Hampton, to succeed the late Dr. Frederick T. Fitch.

Milk-Borne Epidemics—Two milk-borne outbreaks were reported to the state health department in June. In one, nineteen cases of paratyphoid B fever affected ten families among consumers of milk handled by a paratyphoid B carrier. The other was an outbreak of mild gastro-enteritis involving eighty-four persons, members of fifty-five families, all using milk from a dairy which supplied 300 quarts per day out of a total supply of about 4,500 quarts for the community. Investigation disclosed mastitis in some of the cows. In the last ten years nineteen milk-borne outbreaks have been reported in Connecticut. Seven occurred in 1925 and the other twelve during the succeeding nine years at the rate of one or two each year.

with no outbreak in 1927. Of the seven in 1925 four were of typhoid, two of paratyphoid and one of septic sore throat. Of the twelve during the subsequent years, four were of scarlet fever, three of septic sore throat, three of typhoid, one of paratyphoid and one of undulant fever. The state health department points out that this list of outbreaks does not include the numerous instances in which one or two cases of undulant fever were traced to milk. The outbreak of undulant fever, which consisted of fourteen cases with three deaths, occurred in 1934 among users of one milk supply.

DISTRICT OF COLUMBIA

New Dean at Georgetown—David V. McCauley, S. J., has been appointed dean of Georgetown University School of Medicine, succeeding Dr. William Gerry Morgan, who recently announced his retirement. Father McCauley was from 1928 to 1930 professor and head of the department of biology at Canisius College, Buffalo, N. Y. In 1931 he went to Jesuit Pontifical University, Woodstock, Md., as professor of biology and experimental psychology, and in 1934 was named regent of the Georgetown University Schools of Medicine and Dentistry.

Course in Public Health Teaching—A four year integrated curriculum in public health teaching has been established at George Washington University School of Medicine, Washington, to parallel its curriculum in mental health established three years ago under Dr. William A. White. The public health course has been made a part of the regular medical course for the degree of doctor of medicine but is open also to special and graduate students in the public health field. Courses in community health, sanitation, hygiene, preventive medicine and the public health aspects of medicine and surgery are included. The faculty is composed of:

Dr. Roscoe Roy Spencer, Dr. Warren F. Draper, Dr. Walter L. Treadway, Dr. Royd R. Sayers, Dr. William C. White, Dr. Louis L. Williams, Dr. Raymond A. Vonderlehr, Dr. Estella F. Warner, Leslie C. Frank, C. E. Ralph, E. Tarbett, B. S. Selwyn, D. Collins, Ph. D.

Other new appointments to the faculty and staff for the coming year include those of Arnold K. Balls, Ph. D., as adjunct professor of biochemistry, and Dr. Edward Lewis, assistant professor in pediatrics.

GEORGIA

Society News—Drs. Rudolph A. Bartholomew, Atlanta, and Roy R. Kracke, Emory University, presented a paper entitled "The Role of the Hypercholesterolemia of Pregnancy in Causing Vascular Changes in the Placenta Predisposing to Infarction and Toxemia" before the Fulton County Medical Society, Atlanta, September 19. A symposium on proctology was presented September 5 by Drs. Marion C. Pruitt, Ward Beecher, Duvall, George F. Eubanks, Jr., Weldon E. Person, Charles E. Hall, Jr., and Hulett H. Askew.—Dr. William L. Pomeroy, Waycross, read a paper on "Surgical Diseases of the Thyroid Gland" before the Ware County Medical Society, Waycross, September 4.

ILLINOIS

Typhoid Outbreaks—Raw milk was responsible for three outbreaks in July, two of typhoid and one of gastro-enteritis, according to the state health department. More than thirty cases of typhoid with one death were reported at Grand Tower and Windsor, while twenty-five cases of severe gastro-enteritis occurred at Enfield (THE JOURNAL, August 17, p. 519).

Tests Show Drivers Unfit for Speeding—Tests on 3,837 persons at the recent state fair in Springfield showed conclusively that the mental processes of nearly half of them are so slow that it is not safe for them to drive automobiles at high speed. The tests were conducted by the state health department as features of the exhibit on health and safety, to determine the skill of automobile drivers. One third of the persons tested required five eighths second to apply the brakes on an automobile after a visual signal was given while one in each ten tested required at least three-fourths second. The health department points out that, since at 60 miles an hour a car travels 88 feet per second, the importance of delayed mental response to an emergency situation is apparent. It further points out that motor accidents are now the cause of 2,500 deaths and more than 70,000 painful injuries annually in Illinois.

Chicago

Society News—Officers of the Chicago Urological Society, elected at the recent annual meeting are Drs. Benjamin E. Ellis, president, William J. Baker, vice president, and Colquitt Otis Ritch, secretary.—A symposium on the present concept of focal infection was presented before the Chicago Dental Society at a meeting, September 17. Speakers were Dr. William P. Murphy, Boston, Boyd S. Gardner, D. D. S.,

Rochester, Minn., and Dr. Lloyd L. Arnold, who presented the views of the internist, dentist and bacteriologist, respectively.—Dr. Frank H. Lahey, Boston, will address the North Side Branch of the Chicago Medical Society, October 3, on "Newer Aspects of Hyperthyroidism and Hyperparathyroidism, Together with a Consideration of Total Ablation of the Thyroid."—Dr. Sarah A. Pearl will present a paper before the Chicago Council of Medical Women, October 4, entitled "A New Active Principle of Ergot and Its Clinical Significance."

INDIANA

State Medical Meeting in Gary, October 8-10—The eighty-sixth annual session of the Indiana State Medical Association will be held in Gary, October 8-10, with headquarters at the Hotel Garv, under the presidency of Dr. Walter J. Leach, New Albany. The following physicians will participate among others:

Isaac A. Aht, Chicago, Management of the Infant During the First Three Months of Life.
Ralph M. Waters, Madison, Wis., Inhalation Anesthesia, Newer Developments.
Norman F. Miller, Ann Arbor, Mich., Cesarean Section.
Louis J. Karnosh, Cleveland, Clinical Aspects of Frontal Lobe Disease.
Abe L. Schwartz, Cincinnati, Professional Anesthesia, A Hospital Plan in Operation Eighteen Years.
Virgil S. Counseller, Rochester, Minn., Some Changing Concepts Regarding the Endometrium and Their Significance.
Sanford R. Gifford, Chicago, Problems of Senile Cataract.
Elfeous T. Bell, Minneapolis, Pathology of Tumors of the Breast.
William F. Braasch, Rochester, Minn., Recent Advances in the Treatment of Infections Involving the Urinary Tract.
Louis G. Herrmann, Cincinnati, Passive Vascular Exercise Method of Treating the Obstructive Arterial Diseases of the Extremities.
Emmet F. Horine, Louisville, Ky., Practical Management of Cardiovascular Emergencies.

In addition, the various section programs will be presented by Indiana physicians. At the annual banquet Dr. Everett E. Padgett, Indianapolis, immediate past president, will receive the certificate of merit. Speakers will include Dr. James Tate Mason, Seattle, President-Elect, American Medical Association, on "The Work of the American Medical Association," and Dr. Karnosh, "Insanities of Famous Men." The annual golf and trap shooting tournaments will be played Tuesday morning, October 8. Entertainment will include luncheon, a buffet supper, smoker and stag party. The woman's auxiliary to the association will meet, October 8-9.

IOWA

Graduate Courses in Therapeutics—The speakers bureau committee of the state medical society opened its graduate course on general therapeutics in Davenport, September 13, to continue every Friday until November 15. Physicians presenting the lectures are:

George B. Eusterman, Rochester, Minn., Treatment of Gastro-Intestinal Disorders.
Roy W. Scott, Cleveland, Modern Aspects of the Treatment of Hypertension.
William F. Braasch, Rochester, Minn., Treatment of Infections of the Genito-Urinary Tract.
Oliver S. Ormsby, Chicago, Diagnosis and Treatment of Common Skin Disorders.
Everts A. Graham, St. Louis, Treatment of Diseases of the Gallbladder.
Walter Freeman, Washington, D. C., Diagnosis and Treatment of Neuroses.
Bernard Fantus, Chicago, Recent Advances in Therapeutics.
William P. Murphy, Boston, Modern Treatment of Anemia.
Ernest E. Irons, Chicago, Immunologic Therapy.
Howard L. Beye, Iowa City, Surgical Treatment of Diseases of the Lungs and Pleura.

A combined course in medicine and surgery opened at Cherokee September 19 and will continue to November 21, presented by members of the faculty of the State University of Iowa College of Medicine. Courses have been started also at Charles City and Newton.

New Board in Basic Sciences—The Iowa basic science law enacted by the forty-sixth general assembly became effective July 4. The first meeting of the board of examiners in basic sciences appointed by the governor, was held in Des Moines, July 9. Members of the board are:

Joseph H. Bodine, Ph. D., professor and chairman, department of zoology, State University of Iowa, Iowa City.
Edward A. Benbrook, V. M. D., professor and head, department of veterinary pathology, Iowa State College, Ames.
Benjamin H. Peterson, Ph. D., professor and head, department of chemistry, Coe College, Cedar Rapids.
William L. Strunk, D. Sc., professor of biology, Luther College, Decorah.
Charles H. Carter, Ph. D., professor of biology, Parsons College, Fairfield.
Robert E. O'Brien, Ph. D., president, Morningside College, Sioux City.

At the meeting, July 9, Professor Strunk was elected chairman and Professor Benbrook, secretary. The new law requires that no member of the board shall hold a degree in any of the healing arts. The act does not apply to Christian scientists.

or to those holding licenses in any of the healing arts or related professions in Iowa. Nor does it apply to students regularly registered enrolled and in attendance as of July 1, 1936 in accredited schools of medicine, osteopathy or chiropractic in the state. With these exceptions, the law will affect all persons who hereafter apply for licenses to practice medicine or surgery, osteopathy and surgery, chiropractic or any other system or method of healing hereafter to be legalized in Iowa who will be required to present a certificate of having successfully passed an examination in the six basic sciences, anatomy, physiology, chemistry, pathology, bacteriology and hygiene. The first examination will be held October 8-10. Iowa is the ninth state to enact a basic science law.

MICHIGAN

Society News—Dr. Loren W. Shaffer was elected president of the Detroit Dermatological Society at its recent annual meeting.—Dr. Ira G. Downer, Detroit, addressed the Kent County Medical Society June 27, on "Obstructive Lesions in the Kidney."—Dr. William A. Hudson, Detroit, addressed the Berrien and Cass County medical societies July 24 on pulmonary tuberculosis.—The Muskegon County Bar Association was entertained by the Muskegon County Medical Society, August 23, at the first joint session in five years. Speakers included Milton D. Schanecutt, assistant attorney general of Michigan, on "Interdependence of the Medical and Legal Professions" and Harry Rogers, Grand Rapids, "Legal Aspects of Medical Problems."—Dr. Grover C. Penberthy, Detroit, addressed the first of the monthly fall meetings of the Calhoun County Medical Society, Battle Creek, September 3 on fractures.—Dr. George L. Waldbott, Detroit, addressed the Oakland County Medical Society, September 18 on Allergic Theory of So Called Thymic Death and Its Practical Applications.

MISSOURI

Follow-Up Study of Encephalitis Epidemic—Six persons who displayed physical signs of the continuance of encephalitis acquired in the St. Louis epidemic in 1933 were found during a recent follow-up study described in the annual report of the health commissioner. According to a newspaper account the study consisted of a physical examination and a questionnaire designed to reveal the immediate and lasting effects of epidemic encephalitis. This is the second follow-up study made. Although efforts to examine 874 patients were made, examinations of only 331 were reported. A total of 175 had symptoms of the disease in one form or another, it was stated, and eighty-two reported no complaints of any kind. Two persons have since died from other causes and one has become insane. Of those examined, 236 stated they were perfectly well before acquiring the disease, ninety-five were not. Since recovery seventy-nine are better, 111 are worse and 141 the same. 265 are now working and sixty-six were unable to return to their work, nearly one half of these being unable to find employment. 228 of the cases investigated were classed as severe, 103 as mild. One hundred and sixty-four persons reported they were suffering from nervousness and 135 said they were troubled with headaches. Food tastes for fourteen have changed and sixteen find difficulty in smelling, seventy experience trouble in walking and sixteen have suffered speech disturbances. Dizziness, fatigability, weakness, irritability, excitability and inability to concentrate are reported by a variable number. Sixty-five said they still suffered from sleeplessness. The results of the survey and further procedure will be studied at a meeting of the follow-up committee of the Metropolitan Health Council which is planned in the near future, it is reported. There were 221 deaths reported in the epidemic that occurred in St. Louis and St. Louis County during the summer and fall of 1933.

NEBRASKA

Agreement for Medical Relief Ends—Cooperation of the Nebraska State Medical Association with the Nebraska Emergency Relief Administration in an arrangement to give medical service at reduced cost during the emergency created by the depression has been terminated by a new acting administrator of relief, who discontinued the services of the coordinator named by the association and announced that his office would deal directly with physicians. The association's committee on public policy and legislation in a statement in the *Nebraska State Medical Journal* said that physicians have worked harmoniously for a year with the relief administration under the former director under an agreement that was to run during the emergency or until either party had reason to withdraw. With the end of the emergency in sight with the profession growing restless and a fear arising that the precedent is to be established and with the dismissal of the coordinator the com-

mittee sees no reason for continuing efforts as a body at cooperation according to the statement. Because of the inadequate provision for medical care in the relief budgets the service has been unsatisfactory and of a type that the well trained physician does not care to render it continued. The committee listed several complaints frequently heard from physicians participating in the arrangement. They included red tape, which was often irritating and prevented satisfactory service establishment of precedent for payment of fees below the cost of the service domination by welfare workers of a field in which they had no experience, gradual placement of all emergency cases on relief service to unemployables hence not an emergency problem and building up a riffraff practice made up of persons expecting but not appreciating the service.

NEW YORK

Commission Studies Disease Control—A special commission of New York physicians spent several weeks in August studying methods of controlling venereal disease in the Scandinavian countries. Members of the group were Drs. Thomas Parran, Jr., Albany, state commissioner of health, John L. Rice, health commissioner of New York City, Thomas P. Farmer, Syracuse, chairman of the committee on public health and medical education of the Medical Society of the State of New York and David J. Kaliski representing the New York County Medical Society. Dr. Parran was to go on to Budapest to attend the Ninth International Congress of Dermatology and Syphilology as chairman of the United States delegation.

Health at Albany—Telegraphic reports to the U. S. Department of Commerce from eighty-six cities with a total population of 37 million for the week ended September 14 indicate that the highest mortality rate (154) appeared for Albany and the rate for the group of cities as a whole was 97. The mortality rate for Albany for the corresponding week of 1934 was 95 and the rate for the group of cities, 99. The annual rate for the eighty-six cities for the thirty-seven weeks of 1935 was 115, the same as for the corresponding period of last year. Caution should be used in the interpretation of these weekly figures, as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or that they have large Negro populations may tend to increase the death rates.

New York City

Lectures for the Public—Dr. Walter Bradford Cannon, George Higginson professor of physiology, Harvard University Medical School, Boston, will give the first of a series of lectures for the public at the New York Academy of Medicine October 3. Dr. Cannon's subject will be "The Wisdom of the Body."

Society News—A clinical session on chronic pulmonary diseases will be held in the amphitheater at Cornell University Medical College, October 2, under the auspices of the Tuberculosis Conference of Metropolitan New York. Dr. Dickinson W. Richards, Jr. will speak on "Clinical Forms of Dyspnea and Their Treatment."

Kings County Afternoon Lectures—The fall series of Friday afternoon lectures sponsored by the Medical Society of the County of Kings, Brooklyn, will begin October 4. Lectures for October will be:

October 4 Dr. Stanley S. Lamm: Convulsions in Infancy and Childhood.

October 11 Dr. Abraham S. Gordon: Chronic Arthritis.

October 18 Dr. Russell S. Fowler: Appendicitis, Acute and Chronic.

October 25 Dr. Thurston S. Welton: Common Obstetrical Problems.

Personal—Dr. Oswald Swinney Lowley, director of the department of urology at New York Hospital, on a recent trip to Mexico addressed the Merida Academy of Medicine in Yucatan on renal surgery and the Academy of Medicine of Mexico City on urologic surgery. He also conducted an operative clinic before members of the university faculty in Mexico City and was guest of honor at a dinner given by the Mexican Urological Association.

Research Program at Rockefeller Institute—The Hospital of the Rockefeller Institute for Medical Research announces that diseases under investigation in its program for 1935-1936 will include aplastic, idiopathic pernicious or severe microcytic anemia, sprue or severe glossitis and stomatitis without anemia, nephritis in its initial stages, nephrosis, arteriosclerotic nephritis and hypertension in subjects under middle age, advanced heart failure in all age groups, early acute rheumatic fever and acute sore throat in rheumatic subjects, measles, chickenpox and encephalitis following measles, vaccinia, chickenpox, whooping cough or the common cold, and acute lobar and bronchial pneumonia preferably in the early stages.

Physicians should communicate by telephone or personal application to the resident physician before sending patients to the hospital

NORTH CAROLINA

Personal—Dr Coy C Carpenter, professor of pathology at Wake Forest College of Medicine, has been appointed assistant dean.

First Graduate Assembly—The Medical Society of the State of North Carolina sponsored the first of a series of graduate assemblies arranged by the committee on graduate study at Banners Elk, August 23-24. The entire session was devoted to study of gynecology and obstetrics, with the following speakers, among others:

- Dr Thomas V Goode Jr Statesville Ectopic Gestation
- Dr Robert A Ross Durham, Serum Tests for Pregnancy
- Dr Paul W Johnson Winston Salem, Elliott Treatment of Pelvic Infection
- Dr Addison G Brenizer Charlotte, Ureteral Transplantations
- Dr Hubert A Royter Raleigh Tumors of the Breast
- Dr Clyde M Gilmore Greensboro Heart Conditions During Pregnancy
- Dr Roy Hamilton Long Morganton Psychotic Manifestations Associated with Pregnancy the Puerperium and the Menopause

Similar sessions will be arranged for physicians in the central and eastern parts of the state, according to plans of the committee, of which Dr Ronda H Hardin, Banners Elk, is chairman.

PENNSYLVANIA

Personal—Dr Frank P Strome, Ashley, has been appointed chief of the bureau of vital statistics of the state department of health to succeed Dr Emlyn Jones, Johnstown.—Dr James I O'Connor, Barnesboro, was appointed medical director of Cambria County, August 1, to succeed Dr William E Matthews, who had served forty-six years.—Drs Charles Seaton Hendricks, Altoona, and Charles S Dutenhofer, Churchtown, were recently advanced to the grades of lieutenant colonel and major, respectively, in the 103d Medical Regiment, Pennsylvania National Guard.

Society News—Speakers before the west section of the Fifth Councilor District Medical Society at Piney Mountain Inn, Adams County, July 18, included Drs Clarence R Phillips, Harrisburg, "A Résumé of Health Legislation in Pennsylvania, 1935 to 1937", George L Laverty, Harrisburg, "Emergency Medical Relief—A Coordinate Project", Ruth H Weaver, Philadelphia, "Prenatal and Maternal Care," and Richard A Kern, Philadelphia, "Clinical Allergy".—Drs Max Levin and John Moore Campbell Jr addressed the Dauphin County Medical Society, Harrisburg, September 3, on "Delirium" and "Epidemiology of Poliomyelitis in Pennsylvania respectively".—Dr Walter E Dandy, Baltimore, addressed the Harrisburg Academy of Medicine, September 17, on "Diagnosis and Treatment of Lesions of the Cranial Nerves".—Dr William L Mullins, Pittsburgh, spoke on "Cardiac Emergencies" before the Fayette County Medical Society, Uniontown, September 5. Drs Jesse O Arnold II, George W Ramsey and James W McKennan, Washington, addressed the society, August 1, on heat therapy.—Dr Jacob Hoffman, Philadelphia, addressed the Lycoming County Medical Society, September 13, on "Diagnosis and Treatment of Functional Menstrual Disorders of Endocrine Origin." At the annual outing of the society at Highland Lake, August 9, Dr James R Rankin, Muncy, was elected "Nestor" of the society, having reached the age of 75 and having practiced fifty years. He received a leather bound album containing his picture, history, and the autographs of the members.—Dr Maurice Brodie, New York, addressed the Main Line Branch of the Montgomery County Medical Society at Haverford, September 9, on "Poliomyelitis Epidemiology and Immunization," and Dr James P Leake of the U S Public Health Service, Washington, D C, discussed the recent epidemics in the South Atlantic states.

TENNESSEE

Community Hospital Opened in Kingsport.—The Holston Valley Community Hospital, Kingsport, with fifty-three beds and eight bassinets, was opened August 9. The new hospital is the seventh sponsored by the Commonwealth Fund of New York in its rural hospital program, under which the fund furnishes about three fourths of the cost on condition that the community provide the remainder of the cost of building and equipment, furnish the site and undertake operating expenses. The Kingsport project cost \$300,000 and includes a separate home for twenty-five nurses. George W Eutsler is director of the hospital and Dr Thomas B Yancey, Kingsport, chairman of the medical staff, which includes twenty-seven physicians in the hospital area. A hospital service plan offering

hospital care to groups of employees for as much as twenty-one days a year for regular payments of 75 cents a month has been announced. The benefits include maternity care after ten months' membership but do not apply to conditions provided for under workmen's compensation laws, chronic diseases or conditions known at the time of application to require hospitalization. At the opening exercises addresses were made by Judge E T Carter, Gate City, Va., of the circuit court of southwest Virginia, Dr Eugene L Bishop, Nashville, director of health of the Tennessee Valley Authority, and Mr Barry C Smith, general director of the Commonwealth Fund. Rural hospitals previously built by the Commonwealth Fund under the same plan are at Murfreesboro, Farmville, Va., Glasgow, Ky., Farmington, Me., Beloit, Kan., and Wauseon, Ohio.

WEST VIRGINIA

Veteran Physician Honored—The Barbour-Randolph Tucker County Medical Society observed the ninety-ninth birthday of Dr John Woodbridge Bosworth, Philippi, September 3, with a special meeting at Philippi. Dr Charles B Williams, Philippi, son-in-law of Dr Bosworth, presided. Dr Bosworth was born at Beverly, then in Virginia, in 1836, according to family records. He graduated from Virginia Military Institute and was attending Jefferson Medical College, Philadelphia, when the Civil War opened. After the war he settled in Philippi and practiced until about five years ago. Several years ago he was made an honorary member of the Barbour-Randolph-Tucker society.

PUERTO RICO

Personal—Joseph H Axtmayer, Ph.D., has recently returned to the School of Tropical Medicine of the University of Puerto Rico, conducted under the auspices of Columbia University, after a year of research in biologic chemistry at the University of Rochester, and Mr Luis Hernández from special study in clinical pathology at the University of Michigan Medical School, Ann Arbor. Other members of the faculty who are studying in the United States and Europe include Dr Enrique Koppisch of the department of pathology, who is at Basel, Switzerland, studying filtrable viruses on a fellowship from the Rockefeller Foundation, Mr Luis M González, at the Henry Phipps Institute of the University of Pennsylvania, Philadelphia, for study of tuberculosis, Mr Americo Pomales Lebron at the University of Michigan for a doctorate in bacteriology, Dr Rafael Rodríguez-Molina and Mr Félix Lamela at the University of Chicago for courses in hospital management and administration.

GENERAL

License Lost—Dr Russell M Gray, Indio, Calif., has reported that his license to practice medicine in California has been lost or stolen from his office at Indio. The number of his license, issued Aug 11, 1927, is A-04497.

Saleswoman Is Impostor—A woman using the name Kate C Adams is reported to have taken orders in Jamestown N D, for uniforms, posing as a representative of the Maid-Rite Uniform Company, 3717 Monmouth, Cincinnati. She carried a sample uniform and a catalogue and collected an advance payment on orders. Investigation by her victims in Jamestown revealed that there is no such firm in Cincinnati.

Society News—The forty-third annual meeting of the Association of Military Surgeons of the United States will be held in New York, October 3-5, at the Waldorf-Astoria, under the presidency of Dr William Seaman Bainbridge, New York. Brig Gen Frank T Hines Administrator of Veterans' Affairs, Washington, D C, will be a guest speaker.—The annual convention of the American Red Cross will be held in Chicago, May 11-14, 1936.

Fraudulent Salesman—A Utah physician reports that he ordered a suit of clothes through a salesman who claimed to represent the "Mastercraft Tailoring Company, Inc." of Durham, N C. The physician paid \$175 as a down payment, the remainder of the cost to be paid on delivery of the suit. When the suit did not arrive in a reasonable time, he wrote to the firm and his letter was returned with the information that such a firm did not exist in Durham. The salesman used the name H B May.

Casselberry Prize to Be Awarded—The secretary of the American Laryngological Association, Dr James A Babbitt, Philadelphia, announces that the Casselberry Prize of \$500 is open to competition for work in laryngology and rhinology. The award was established by the late Dr William E Casselberry, Chicago, who left a fund to the association, the interest from which was to be awarded in sums of \$500 or less for a prize award, a decoration or the expense for original invest-

gation in laryngology and rhinology. These or reports of work must be in the hands of Dr Babbitt, 1912 Spruce Street, Philadelphia, before February 1 of any given year.

Impostor Poses as Poliomyelitis Expert—From Lexington, Ky., comes a report of a man who appeared in the town September 2 posing as a representative of the U S Public Health Service investigating the poliomyelitis outbreak in Kentucky. After registering at the Phoenix Hotel under the name "Dr Robert Coldwell" and explaining that he came from Johns Hopkins Hospital, Baltimore, as a special representative of the federal health service, the man visited the county health officer, who took him on an "inspection trip" in Lexington and to Paris, where the impostor said he would set up an organization. He carried a brief case filled with medical and health literature and displayed hypodermic syringes, mentioning frequently the number of spinal punctures he had made on afflicted children. With the chairman of the board of governors of the Lexington unit of the Shriners' Hospital for Crippled Children, who is also the manager of the Phoenix Hotel, "Coldwell" visited the hospital. While there he asked if the public health service was paying the hospital an allotment of \$142 per capita for the care of indigent children with poliomyelitis said that there must be some oversight in the matter and that he would communicate with the surgeon general about it. Suspicion was soon aroused by his activities and verbosity, especially when it was found that he had had a local printer make up some report cards for him headed "Special Memo United States Public Health Service." Meanwhile he had cashed checks amounting to \$55 at the hotel. A telephone call to the bank revealed that "Dr Coldwell" had no account another to Johns Hopkins that he had not been employed by the hospital and a telegram to the public health service that he was not an official representative. About two hours before it was decided to have the man arrested he disappeared, leaving some syringes and vials of so-called serum in his room. Later it was learned that a man of his description had been in Louisville the previous week, working at Red Cross Headquarters where he said he was organizing a group of nurses to operate from Berea in preventing spread of poliomyelitis in south eastern Kentucky. This man is about 40 years old, 5 feet 9 inches tall, smooth shaven, with a full face and Roman nose. Later investigation by the public health service revealed that in 1931 the state health officer of Ohio reported a "Dr Robert Coldwell," who had concerned himself with an investigation of a typhoid epidemic at the State Hospital for the Insane at Cleveland, claiming to be a special representative. At that time it was reported that the man had never been employed by the service.

CANADA

University News—The University of Toronto Faculty of Medicine will offer a two weeks course in pediatrics to the physicians of Canada, November 4-16.—The University of Manitoba Faculty of Medicine presented a graduate course in cooperation with the Manitoba department of health September 9-14, among speakers were Drs Jonathan C Meakins, president of the Canadian Medical Association and William V Cone, Montreal, Robert I Harris, Toronto, and George J Wherrett, Ottawa, executive secretary of the Canadian Tuberculosis Association.

Personal—Dr William A Scott, assistant professor of obstetrics and gynecology, University of Toronto Faculty of Medicine, has been appointed head of the department, to succeed Dr William B Hendry, who recently resigned.—Dr Robert M Benvie, Stellarton, was elected president of the Medical Society of Nova Scotia at the annual meeting in Sydney, July 3-4, and Dr Harry G Grant, Halifax, secretary.—Dr Allan Roy Dafeo, Callander, Ont., received the Order of the British Empire from King George V in the list of honors issued on the occasion of the king's birthday and his silver jubilee.—Dr Joseph L Jackson, assistant professor of anatomy at the University of Manitoba Faculty of Medicine has been appointed professor of anatomy at the University of Saskatchewan School of Medical Sciences to succeed the late Dr Robert T McGibbon.

CORRECTION

Agranulocytosis—In the special article entitled "Agranulocytosis," by Roy R Kracke and Francis P Parker (THE JOURNAL, September 21, page 960), there appears a list of American proprietary preparations that did or do contain amidopyrine. The list was in error in including Analgin and Antabs, both of the William S Merrell Company, because these two preparations do not contain and never have contained amidopyrine, according to a statement from the firm.

Government Services

Changes in Public Health Service

Drs James P Leake, Lawrence Kolb and Hermon E Hasseltine have been promoted and commissioned as medical directors in the regular corps of the service. Dr Hasseltine was recently relieved of his duties at San Francisco and assigned to Carville, La, in charge of the marine hospital. The promotion and commission of the following physicians as senior surgeons in the regular corps has also been announced: William S Bean Jr, Gleason C Lake, Thomas B H Anderson and Herbert A Spencer.

Examination for Psychiatric Position

The U S Civil Service Commission announces an open competitive examination for a position as psychiatric medical supervisor for the Department of the Interior to have charge of the 300 legally adjudged insane of Alaska, confined in Morningside Hospital, Portland, Ore, which is operated under contract with the United States. The position carries a salary of \$5600 a year, subject to a deduction of 35 per cent toward a retirement annuity. Applicants must have graduated from a recognized medical school, must have had either a regular rotating or a psychiatric internship of one year or experience considered equivalent to such internship and must have had not less than five years of responsible and progressive specialized experience in neuropsychiatry, of which at least three years must have been in a senior administrative capacity in a mental hospital with a daily average of not less than 300 patients under their care. They must not have reached their fifty-third birthday and must be in sound physical health. Further details and application forms may be obtained from the secretary of the Board of Civil Service Examiners at any first class post-office from the commission at Washington, D C, or from the district offices of the commission at Atlanta, Boston, Chicago, Cincinnati, Denver, New Orleans, New York, Philadelphia, Seattle, St Louis, St Paul, San Francisco, Honolulu, Balboa Heights, C Z or San Juan, P R. Applications must be filed not later than October 6.

Department of Vital Statistics Reorganized

With the completion of the primary objective of the department of vital statistics of the U S Bureau of the Census, namely, the extension of birth and registration areas which has been its concern for about thirty-five years, a reorganization is now under way to undertake new tasks. In 1933, on the completion of this work with the admission of Texas, the joint advisory committee of the director of the census took steps to explore the various questions and problems involved. A report of this study points out that "while it is still necessary to work for more complete and accurate recording of the facts as to births and deaths, new and intensive efforts can be devoted now to analytical treatment of the data and to the presentation of more refined results. A better statistical basis for public health work will be laid, and for all studies of population structure and changes." The appointment of new supervisory personnel in charge of each of three important types of functions within the division is announced, following the recommendations contained in the report. Dr Halbert L Dunn, formerly director of the University of Minnesota Hospitals and professor of biometry, University of Minnesota Graduate School of Medicine, Minneapolis, has been placed in charge of the division as chief statistician. He will also have charge of research and analytic developments which are also included in the reports recommendations. Dr John Collinson Jr, recently registrar of vital statistics for the state of Maryland and secretary, American Association of State Registration Executives, as assistant chief statistician, will be in immediate charge of the development and perfection of registration and of relations with state health officers and registration officials. A technical assistant to the chief statistician will be appointed to have immediate charge of the classification and coding of causes of death, the development of the joint manual, representation of the division respecting changes in the International List, and relations with medical schools and the medical profession. Forrest E Linder Ph D, who resigned from a position with the Worcester (Mass) State Hospital, will assist in the development of the program. Six field agents will be appointed and the districting of the United States for this purpose is proposed. Dr Timothy F Murphy, the present chief statistician, has been appointed to take charge of a newly established division of religious statistics, general information and records.

Foreign Letters

LONDON

(From Our Regular Correspondent)

Aug 31, 1935

The Campaign Against Noise

In a previous letter, the formation was reported of the Anti-Noise League to combat the growing torment of noise, which is injurious both to the sick and to the well. The movement began about two years ago with a letter to the *Times* by some well known persons, including members of the medical profession such as Lord Horder, Sir James Purves-Stewart (neurologist) and Dr. Dan McKenzie (otologist), asking for assistance in the formation of the league. The response was excellent. The revolt against noise has crystallized into a campaign supported by thousands of people. The report which has just been issued, states that the league had to meet two criticisms. It was stated that noise had always existed in cities. The reply is that traffic noises have grown more penetrating, more strident and more unhythmically continuous in the last twenty years. The second criticism was that the ill effects of noise on human beings cannot be scientifically assessed. But medical experts testify that the noises of modern civilization produce nervous disorders.

The main difficulty in taking effective action is that there is no simple generally accepted instrument for measuring noise outside the laboratory. Such an instrument would no doubt facilitate the enforcement of the law, but an enlightened public opinion insistent on action and the cooperation of experts who understand the causes of noise with the public who suffer from its effects are the aims to be achieved. Universal support has been given to the league by the press, eminent writers, the National Physical Laboratory, the Ministry of Transport, the Ministry of Health, the Royal Institute of Architects, the British Broadcasting Corporation, and industrial firms and others engaged in research as to noise. The government has issued a regulation prohibiting the sounding of motor horns in the hours of the night but the problem of this evil is not yet solved. At the Oxford conference of the league a resolution was carried aiming at abolition of motor horns altogether except in cases of emergency. It is claimed that the loud and strident horns in use encourage the habit of "driving on the horn" and are responsible for many accidents. Many local authorities have adopted a new model by-law to control wireless loud speakers, phonographs and street musicians. The Westminster city council permits the cost of silencers on road drills to be added to quotations for road breaking. Milk distributors are cooperating by replacing milk carts by silent electric vans and pneumatic-tired horse vans, and rubber devices are being used in glass and metal containers. Railway companies are taking steps to reduce the blowing of whistles and to deaden the noises of platform trucks by the use of rubber linings.

Crank Medical Cults in England

Sir Ernest Graham-Little (dermatologist and member of parliament) has done good service by his exposure, in communications to the *British Medical Journal*, of some of the crank medical cults that exist in England. The Medical Herbalists publish a monthly journal described as the organ of the 'National Association of Medical Herbalists of Great Britain,' who have in London what they call the 'College of Botanic Medicine.' This appoints 'an education committee of which four "principals" (none medically qualified) are said to give instruction in anatomy, physiology, materia medica and therapeutics, pathology and physical diagnosis, diseases of women and children and chemistry.' There is further a system of postal tuition in these subjects forming part of the course

leading to the issue of "qualifications" to practice. On the passing of examinations, "degrees" enable the herbalist to put LCBM and M.N.A.H.M. after his name. There is also a still higher "degree," DBM (Doctor of Botanic Medicine) to be obtained on presentation of a "thesis" and payment of a fee of \$125. The same amount is payable for the course. The dangerous nature of this cult is shown by the number of coroners' inquests in which herbalists figure. But this is a free country and they seldom are even censured. The only thing that can bring them within the grip of the law is representing themselves to be qualified physicians, which they avoid.

Another cult is the "Naturopaths" who since 1934 have established a "register," which is claimed "to protect the public and the fully trained naturopath from those who with inadequate knowledge claim to practice as nature-cure physicians." In a printed form of registration issued by this body, an applicant is asked to specify types of treatment which he gives and the following are cited as examples of such treatment "psycho-analysis, colonic lavage, electrotherapy, biochemistry, herbal medicine, orificial surgery." A circular issued with the application form reads "Our standard of professional education is four years' full-time training with clinical experience. As the profession is still young, however, it has been impossible for many now in practice to obtain such complete equipment. We are therefore following the example set by other young professions and accepting proportionate experience in practice in lieu of a certain amount of training." It seems to be a common form with the irregular cults (probably in imitation of the most blatant of them—osteopathy) to name four years' training (usually fictitious) as the basis of "professional education." But no mention is made of the school where the applicant for registration in 'naturopathy' can get his training.

The most successful of all the cults in capturing the British public is osteopathy, an American importation. The British School of Osteopathy, founded in 1917 posed as giving its 'graduates' a four years course until its devastating exposure, which was described in *THE JOURNAL*. The first two years was declared to be "the same course as medical students take" and 'the dean' received the honor of publication in the *Times* of a half-column letter in large print.

Sir Ernest Graham-Little thinks that the present rage for setting up 'registers' of these irregular practitioners deserves the attention of the medical profession. He has drawn the attention of the minister of health to the scandal of these schools fraudulently pretending to qualify persons to practice various branches of medicine and surgery and has received his promise to look into the matter.

Assistance to Scientists the Victims of Political Persecution

The annual report of the Academic Assistance Council formed under the presidency of Lord Rutherford to assist the scientists and scholars the victims of political persecution on the continent who have been deprived of their means of living has been issued. Up to June 1935, out of 1,300, 650 left Germany and of these 287 are now permanently placed. Of the 287, seventy-six are workers in medicine or its ancillary sciences, forty are chemists, thirty-seven are economists, twenty-five are physicists and twenty are mathematicians. Of those permanently placed, seventy-six are in the United States, fifty-seven in Great Britain, thirty-eight in Turkey and thirty in Palestine. Temporary placements of 336 have been effected, of which 155 are in Great Britain, a larger number than in any other country. The next largest number is fifty-eight in the United States. Of the temporary placements, sixty-seven are of medical workers. During the year the council received in donations and subscriptions (mainly in small sums) \$100,000 and grants from Jewish charitable organizations to the extent of \$17,500. The council proposes to end its emergency grants

by July 1936, though it recognizes that even then some deserving scholars and scientists will not have been reestablished. It is felt that to continue emergency work beyond three years would be difficult to justify. But, if sufficient financial support is available, the council hopes to establish a limited number of research fellowships to maintain in this country workers of special distinction or promise, particularly in the humanities and subjects in which it is difficult to find semipermanent positions elsewhere.

Protection Against Air Raids

In a previous letter, arrangements recommended by the government for the protection of the civilian population against air raids were reported. The subject is considered so important that a series of publications is to be issued. One has just appeared on Treatment of Casualties and Decontamination of Personnel. The first step recommended is to draw up a general plan for each district. This is primarily a matter of forming the appropriate organization and preparing lists and schedules of buildings and equipment required. Next comes training of personnel and finding what equipment is needed to supplement that already available. The government will arrange to supply respirators, protective clothing and bleaching powder. The memorandum distinguishes four classes of patients who may require attention: (1) those suffering from injuries due to bomb explosions or fire but not affected or contaminated with gas; (2) those suffering from such injuries and also affected or contaminated with gas; (3) those who require treatment because they have inhaled gas or whose skin has become contaminated with gas; (4) those who do not require medical treatment but whose clothing has been contaminated with gas. It is recommended that all should be dealt with by a single organization, which would combine the normal type of ambulance and hospital service for the treatment of accidents, with special arrangements for dealing with gas contamination of persons and their clothing.

The following organization is outlined: 1. Mobile first aid parties for dispatch to any place where air raid casualties have occurred. 2. First aid centers and decontamination centers (preferably combined) to which persons with minor injuries or suffering slightly from gas or with contaminated clothing can proceed independently for treatment and, if necessary, change of clothing. 3. Casualty clearing hospitals to which more serious cases could be taken by ambulance and if not fit for immediate transfer to base hospitals, detained and treated. 4. Base hospitals situated, so far as possible outside areas of special danger, for cases evacuated from casualty clearing hospitals as soon as fit to be moved. Separate base hospitals may be impracticable in some cases. 5. An ambulance service for use in conjunction with first aid parties and for the movement of stretcher cases from first aid centers to casualty clearing hospitals and from these to base hospitals. 6. Laundry services for decontamination of clothing. 7. A clerical organization for keeping records of casualties, their property and valuables and their places of treatment.

The manning of the various services will require special staffs. For preference, men under 25 should not be enrolled. So far as possible the first aid and decontamination centers should be selected in advance and the personnel trained. Arrangements should also be made in advance for supplementing in case of need the nursing staff of hospitals selected as casualty clearing hospitals and supplementing or perhaps creating staffs of base hospitals. Arrangements for anti gas instruction of these nurses should be made wherever possible. On a threat of air attack, beds in casualty clearing hospitals should be freed by removal to outlying hospitals, existing or improvised of all patients who can be removed with safety. Thereafter no patients, whether air raid casualties or not, should be accepted for lengthy treatment unless unfit to be

taken elsewhere. Following a raid no casualties fit to be removed to base hospitals should be retained in casualty clearing hospitals.

In rural areas, reliance for first aid should be primarily placed on the local physicians and district nurses and the local Red Cross society. This might be supplemented by mobile first aid parties from neighboring towns. County councils are recommended to plan out large areas for the organization of complete schemes providing for casualty clearing and base hospitals, the latter to be shared, possibly, with a neighboring county or borough group. It would be important to organize mobile first aid parties, with motor transport, in suitable centers, which would cover surrounding districts. Every village should have a call on two or even three first aid parties in a prearranged order.

Tuberculous Milk

The problem of obtaining a milk supply free from tubercle bacilli has so far not been solved. Dr. G. M. Fyfe, health officer for St. Andrews, states in his annual report that about 40 per cent of the cows in the country are infected with tuberculosis and that about one cow in 500 is suffering from tuberculosis of the udder and therefore is producing milk containing the bacilli. In Scotland about 9,000 cases of tuberculosis in man are notified annually. Research has shown that about 4 per cent of persons suffering from tuberculosis of the lungs are infected with bacilli of bovine origin and that for tuberculosis of the bones the incidence is as high as 50 per cent and of the lymphatic glands 85 per cent. Dr. Fyfe states that measures for the eradication of tuberculosis from dairy herds are alarmingly defective. The schemes in force are voluntary and are undertaken only by a few enlightened dairymen.

Reinforcement of the Immunizing Action of Toxins and Antitoxins

Guinea-pigs and rabbits in laboratory work can be immunized by the injection of the diphtheria and tetanus anatoxins. G. Ramon and Lemetayer, in a paper read at the May 6 meeting of the Academy of Sciences, call attention to the fact that this immunity can be greatly increased by adding to these antigens such substances as tapioca, cholesterol and hydrous wool fat. One can immunize rabbits against tetanus by means of a single dose of unmodified tetanus toxin in hydrous wool fat. The authors have attempted recently to apply these principles to the antitetanic immunization of domestic animals such as the horse and sheep. In the production of antitetanus serum, this method utilizing either the toxin or anatoxin, will greatly shorten the time necessary to immunize the animal from which the serum is to be obtained. Using anatoxin their method will greatly facilitate the vaccination of domestic animals against tetanus; the immunity thus obtained taking place more rapidly and being of longer duration than is at present possible.

Theory on Etiology of Eclampsia

At the June 4 meeting of the Academy of Medicine, Metzger stated that eclampsia was the result of abnormal mobilization of proteins. To provide for the needs of the fetus the mother builds up reserves in her tissues. When the fetomaternal symbiosis ceases to be harmonic, "the nitrogenous reserves suddenly enter the maternal circulation and the result is eclamptic convulsions."

Recent research on the polypeptides enable one to understand such accidents. Disintegration of the tissue albumins produces the polypeptides. Hepatic and renal insufficiency result in inability of these viscera to destroy and eliminate the polypeptides. Edema also plays an important part in the distur-

bances of protein metabolism. It is probable that the nitrogen content of the blood throughout pregnancy is low, because the maternal organism constantly utilizes the proteins to build up its reserves.

Metzger reported a case which in his opinion confirms the preceding theory. At the end of six and a half months the patient suddenly ceased to feel fetal movements. Edema of the face and legs, headache, a blood pressure of 180 mm of mercury and marked albuminuria were noted on admission to the hospital eight days later. The uterus was emptied and a dead, very edematous macerated fetus was found. The placenta was very thick. About twelve hours after the operation the patient, who had voided scarcely 500 cc of urine in twenty-four hours, suddenly passed 2,000 cc containing a large amount of albumin. There was only a trace forty-eight hours later, and the albumin and edema had completely disappeared at the end of three days. This is an example of protein intoxication. There was an effort to eliminate the albumin as soon as the fetal death took place, then retention with aggravation of the general condition, followed by massive elimination of albumin and recovery. The death of the fetus does not mean that of the placenta. In this case the placenta was found edematous, the fetal circulation being interrupted by vascular changes in and persistence of the epithelial covering of the villi (Langerhans cells). Metzger thinks that the fetomaternal metabolism is of placental and not of fetal origin. When the placenta is normal, its death occurs simultaneously with that of the fetus. If the placental vitality is abnormal or pathologic, complications cannot be avoided and may necessitate rapid emptying of the uterus. The hypophysis mobilizes the metabolism but the placenta acts in a regulatory capacity.

Use of Spinal Cord of Animals for Nerve Grafting

The advantages of direct end-to-end suture of divided nerve trunks is the ideal method, but one encounters cases in which there is so much destruction that some form of graft must be employed. Up to the present time, only nerve segments from rabbits, calves or dogs have been used as heteroplastic grafts. The failures in most cases were due to imperfect aseptic technique and to the large amount of fibrous tissue that develops between the severed nerve ends, thus rendering the graft impermeable.

Gosset and Ivan Bertrand have attempted to find a tissue with less fibrous elements so that the nerve fibrillae might penetrate it more easily. They also tried to obtain some tissue containing as much myelin substance as possible. The results of their experiments were reported at the June 26 meeting of the Société de chirurgie. As grafts they employed portions of the dorsal spinal cord, chiefly because of the parallel nerve fibrillae and relatively small amount of fibrous tissue. The experiments were carried out on adult rabbits and rats. After removal of the segment of spinal cord needed for the graft, the latter is immediately placed in a 10 to 20 per cent formaldehyde solution to prevent retraction of the removed segment. The coverings of the latter are removed on the following day. A young dog weighing 20 Kg, in which the sciatic nerves had been severed, first on one side and then on the other, was employed for the first experiments, in which spinal cord grafts taken from a rabbit were utilized. Six weeks later, both the functional and the electrical results showed complete restoration of the severed sciatic nerves. A portion of the spinal cord graft, on histologic study, revealed the fact that the graft had been penetrated by newly formed nerve fibrillae from the proximal segment of the divided sciatic nerve, thus preserving the general pattern of the proximal nerve trunk. In recent traumatic nerve lesions or in cases in which the presence of a neuroma necessitates the removal of a relatively large segment of an important nerve trunk the use of this form of graft should be borne in mind.

Peritonitis Due to Calculous Pyonephrosis

At the June 15 meeting of the Société de chirurgie, R. Couvelaire reported a case in which a woman, aged 40, had acute abdominal symptoms of twelve hours' duration. The pain had been felt at the onset in the right upper quadrant but soon became diffuse. Similar attacks had been noted during the preceding three months, accompanied by painful urination and urgency. On admission the pulse was 130, the temperature was 103 F and there was generalized abdominal rigidity, but none over the kidney regions. The preoperative diagnosis was diffuse peritonitis due to perforation of either the gallbladder or the appendix, but both of these were found normal at the exploratory operation, which revealed a diffuse suppurative peritonitis. A mass was felt filling the right iliac fossa, from which pus was escaping through a perforation of the overlying peritoneum. A right nephrectomy was performed. The examination of the specimen revealed a large calculous pyonephrosis with a perforation at its upper pole into the peritoneal cavity. In the discussion, Fey added two similar cases, one due to rupture of a large renal abscess and the other of a pyonephrosis. In both, there was a diffuse peritonitis.

Huet reported a case in which a large pyonephrosis had ruptured into the peritoneal cavity.

Comparative Value of Lumbar and Suboccipital Puncture

Certain syphilologists, especially Sezary, have recently advocated suboccipital puncture for the examination of cerebrospinal fluids in syphilis of the central nervous system. Guillaum and Mollaret read a paper at the May 24 meeting of the Société médicale des hôpitaux de Paris in which they failed to see any advantages in the suboccipital over the lumbar method of puncture. They compared the results of the examination of the fluid obtained by these two methods. Such a comparison must first of all be based on the position of the patient at the time the puncture is made. If the patient is in a straight sitting position, the fluid obtained is of cranial origin, if the patient is sitting but leaning forward in the position used for lumbar puncture, the fluid is entirely of spinal origin, whereas, if it is obtained while the patient is lying on the side, the liquid is cerebrospinal. These observations are the result of pressure studies on human beings and on monkeys, which reveal the fact that gravity is the chief factor controlling the escape of cerebrospinal fluid. Other factors, such as respiration, play a subordinate part. Under normal conditions the liquid obtained by lumbar puncture is twice as concentrated in human beings as is that by suboccipital puncture. It is three times more concentrated in monkeys. The albumin content and the colloidal benzoin reaction differ in the liquid obtained by suboccipital and by lumbar puncture. A comparison of the ventricular and lumbar puncture liquids shows still more difference. Suboccipital puncture is followed by serious accidents such as puncture of the medulla or of arteries such as the vertebral and postero-inferior cerebellar. Death may follow suboccipital puncture. These sequelae are rare but must not be overlooked. Lumbar puncture is the only method that yields information as to the condition of the spinal cord and cauda equina in syphilis. The lumbar method is to be especially recommended in agitated and emotional patients, for children and for private practice.

In the discussion, Cathala stated that he had seen two deaths following suboccipital puncture and believed it should be employed only in unusual cases. Tzanck reported an epileptic attack following suboccipital puncture. Basch, on the other hand, had employed the latter method in 140 cases without accident. He preferred it to lumbar puncture in syphilis and advocated the use of needles of fine caliber. Flandin warned against suboccipital puncture in cases of suspected brain tumor. He had observed only one fatal result in 1,000 suboccipital

punctures. In this instance the patient had a generalized syphilitic arteritis and died three days after the puncture.

The suboccipital method is more difficult and requires much experience.

Pinard endorsed the views of Guillain and Mollaret as to neurologic cases but preferred the suboccipital method in cases of syphilis especially in ambulatory patients. He had never observed an accident in more than 600 suboccipital punctures.

De Gennes reported a death from meningeal hemorrhage twenty-four hours after a suboccipital puncture. This method should be seldom employed, owing to danger of injury to one of the vessels.

Guillain stated, in closing, that statistics show one death to 10,000 suboccipital punctures. The suboccipital will not replace the lumbar method. The dangers of the former should be better known than they are at present.

Puerperal Infection Due to Anaerobic Organisms

In the February issue of *Gynecologie et obstetrique* a bacteriologic study of 100 cases of puerperal infection is reported from one of the Moscow maternities by Morosova and his associates.

Weinberg of the Pasteur Institute has called attention to the fact that when an anaerobic infection (B. Welchii) even of slight degree is associated with a B. coli infection the virulence of the anaerobic organism is greatly increased. The authors believe that this is applicable to puerperal infections. The presence of anaerobic organisms (B. Welchii and the anaerobic streptococcus) is a quite frequent finding in the vaginal secretion during pregnancy. One of the most characteristic but rare symptoms of anaerobic puerperal infection is a sense of crepitation on palpation of the uterus, and another is the accumulation of a nonfetid serous peritoneal exudate. The temperature curve is of the continuous type with moderate remissions unless a mixed infection exists, the temperature curve may then vary. Anaerobic infection may involve only the uterine cavity, which is the more favorable type or it may involve the wall with evidences of a generalized infection of a very severe character. In 38 per cent of the 100 cases, the organisms found were B. Welchii and the anaerobic streptococcus. In 25 per cent only B. Welchii was found, and in 20 per cent only the anaerobic streptococcus. The most virulent cases were those in which B. Welchii and the anaerobic streptococcus were associated. The aerobic streptococcus was found in the vaginal secretion of all 100 cases. B. Welchii was present in blood cultures in only two cases and the anaerobic streptococcus in one case.

The clinical picture of anaerobic infection is characterized by the early appearance of symptoms of toxemia, by the triad symptoms (jaundice, cyanosis, brownish color of urine and blood serum), rapid formation of exudates (peritoneal), at times abscess formation in the uterine wall, and pelvic cellular tissue. Crepitation on palpation of the uterus is seldom found.

The mortality in mixed anaerobic infections is much higher (from 53 to 66 per cent) than in aerobic infections. As the anaerobic infection destroys the oxygen-carrying function of the erythrocytes with resultant symptoms of asphyxia blood transfusion is indicated in conjunction with serum therapy.

Professor Terrien Elected Fellow of Academy of Medicine

By an almost unanimous vote, the ophthalmologist Prof. Felix Terrien has just been made a fellow of the Academy of Medicine. This is one of the highest honors that can be bestowed on a physician in France. Professor Terrien has occupied the chair of ophthalmology at the Faculté de médecine, the only medical school in Paris, since 1925. His contributions to the anatomy and diseases of the eye have been most important.

Problems of Heredity

Since the last report on the subject of sterilization (THE JOURNAL, June 8, p. 2109), a number of important facts have been published. The official journal *Deutsche Justiz* gives the number of court decisions imposing sterilization in 1934. It appears that in 1934 a total of 84,525 petitions were filed, the two sexes being about equally represented. Of these 84,525 petitions 64,499 were heard before the eugenics courts, and in 56,244 instances sterilization was ordered, the representation of the two sexes being about the same. It is evident, therefore, that at the close of the year about 25 per cent of the petitions remained undecided. Of the petitions that were heard, in 93.8 per cent sterilization was ordered, and in 6.2 per cent the petition was denied by the court. The 205 eugenics courts and twenty-six eugenics superior courts participated in the rendering of these decisions. In nearly all appealed cases the decision of the court of first instance was confirmed. Of 8,219 appeals taken against a sterilization order, only 377 were upheld. It is significant to note that in 438 instances (11.9 per cent) an appeal was taken against the rejection of sterilization by the eugenics courts before which petitions were heard, with the result that of the 299 appeals heard by the end of 1934, in 179 the appeal was granted and the decision of the trial court was reversed. With a population of more than 65,000,000, there were 130 petitions per thousand inhabitants, or one petition to each 771.2 inhabitants.

The minister of the interior has issued a bulletin in which he calls special attention to the necessity of all persons who participate in the court proceedings or in the execution of the intervention preserving absolute secrecy. With regard to the suitable time for the sterilization of young women, a eugenics court has expressed the view that the intervention, by reason of the operative technic, should not take place before completion of the fourteenth year.

Statistics on libido, or sexual desire, following late castration have now been collected and published. In a series of fifty-eight male cases collected by Dr. Kolle in Frankfurt-on-Main, as far as information could be secured, in at least one third libido and potency were preserved, although sometimes weakened. On the other hand, de Quervain and Wolf, reporting on their experiences with Swiss patients at the Berne Surgical Clinic, state that in twenty-nine of their series of thirty-five male and female cases complete success (that is, entire suppression of libido and potency) was achieved. From Denmark, Goll reports complete success in forty out of forty-one cases. In a third of the cases, however, the observations extend over a period of only two years. In any event, a large portion of the castrated criminals guilty of sexual offenses do not become repeaters (possibly 30 to 50 per cent).

The opposition to sterilization is strong and is on the increase, at least the voiced objections are more vehement. The Catholics are opposed to it on religious grounds; others because they regard it as undue interference with personal rights. Many have a dread of the operation. The middle classes consider sterilization as a reflection on the dignity of a family. Of late, the ruling party in Germany has taken a strong stand against these objectors. For example, in an article in the correspondence column of the national-socialist party headed "Life or Death," it is strongly emphasized that the life of the nation takes precedence over dogma and conflicts of conscience. Reference is made to the sharp retaliation that will follow continued opposition to the government's plans. At the close of the article the statement is made that such a spirit of opposition is not justified morally or from any other point of view. Likewise Dr. Gross (M.D.) the head of the party's racio-

tical bureau, has expressed himself publicly in a similar manner "Resistance will not be tolerated," he stated, "tolerance and forbearance do not appear to be properly understood in all quarters" Even the minister of the interior felt called on to issue a bulletin in which he expressed the government's intention to take energetic measures to curb the opposition to the law He demands of his subordinates that, if further cases arise, they institute legal proceedings against persons who openly oppose the law and thus promote malicious attacks on the government and the national-socialist party Any attempt on the part of a third party to induce persons who are to be subjected to the intervention to offer resistance to the execution of the order in question and to yield only to direct coercion by the police shall be regarded as unlawful opposition to the law Rust, federal minister of education, recently expressed his views on the subject of "Hereditary Disease in Relation to Our Schools" He urged that in the selection of pupils worthy of a higher education undue weighting of intellectual factors be avoided

- According to this decree, 'carriers of a predisposition to a disease,' although not subject to sterilization, are not suitable to receive a higher education and hence should not be admitted to institutions of higher learning This decree has come in for some criticism, which appears justified, for among such children there are certainly some who would prove valuable members of society and promoters of culture, in spite of slight manifestations of disease that are under the ban of the law, whereas these mild manifestations appear to be taken as seriously as the more grave evidences of hereditary disease Recently hereditary disease was declared an argument in favor of the granting of a divorce, the wife in question being affected with schizophrenia In another case the registrar in a department for the issuance of marriage licenses refused to issue a license because the prospective bridegroom gave evidence of hereditary weak-mindedness The courts supported him in his decision, to which no objections may be raised.

The questions concerning the limitations of interruption of pregnancy in connection with sterilization have not been fully clear, in fact, instructions have been quite contradictory (THE JOURNAL, July 20, p 212) The legislators have, however, again intervened and have ordered that in the case of pregnant women concerning whose sterilization a valid court decision has been issued the pregnancy may be interrupted only so long as the child is not viable that is before the end of the sixth month of pregnancy The previously cited fundamental decision of the Hamburg court is therefore not approved Furthermore, interruption of pregnancy should not be resorted to if such an intervention would entail a serious menace to the life and health of the woman If there are no contraindications, interruption of pregnancy and sterilization should be carried out simultaneously For the execution of these measures the ministry has created special expert centers, which must declare the intervention to be necessary and which are equipped to apply all the precautions that the law requires Only Aryan physicians may serve as experts The experts themselves may not aid in carrying out the intervention The expense will be borne in the given cases by the *krankenassen* or by the welfare centers Every interruption of pregnancy, every miscarriage occurring before completion of the thirty-second week of pregnancy, and every premature birth must within three days be reported in writing to the health officer having jurisdiction, this obligation rests on the physician, the midwife or any other person rendering aid but not on relatives or persons belonging to the same household

Of late, sterilization of all habitual criminals has been proposed, likewise of all criminals who on close scrutiny of their family history, give evidence of their criminal tendencies with the first criminal offense Dr Gerecke, of the Institute of Criminobiologic Research in a penal institution made in 164 cases a search for evidence of familial contamination, which

furnished valuable bases in only eighty habitual criminals. In this investigation only such offenders were considered as had received jail or prison sentences more than seven times The family histories of eighty criminals were studied, and in 157 relatives the deficiencies shown in the adjacent tabulation were discovered

	Alcohol Addicts	Criminals	Weak-minded ness, Epilepsy, Mental Disease	Commercial Unchastity	Totals
Father	32	30	4		36
Mother		10	6	5	21
Brother	3	32	5		40
Sister		9		4	13
Grandfather	5	5			10
Grandmother					
Paternal uncle	1	3	1		5
Paternal aunt				1	1
Maternal uncle		3	1		4
Maternal aunt			3		3
Totals	41	81	20	10	157

These data are incomplete, especially as regards the grand parents The actual number of asocial individuals in these eighty families would doubtless be much greater The same is true of the illegitimate children, whose progenitors are frequently unknown Nevertheless these data constitute valuable material In only fourteen of the eighty families were no evidences of degeneration discovered (which does not prove that there was no degeneration) From the standpoint of hereditary biology, it was evident that there were some dominant and some recessive (or sex-bound) hereditary predispositions.

In Frankfurt-on-Main the largest German heredobiologic center was dedicated as *Universitäts-Institut für Erbbiologie und Rassenhygiene* The institute which is under the direction of Prof Freiherr von Verschuer, is located in the municipal Haus der Volksgesundheit recently erected by the local *krankenkasse* Von Verschuer, who was formerly engaged at the Kaiser Wilhelm-Institut für Anthropologie in Berlin Dahlem will serve at the same time as *orduarus* at the University of Frankfurt The new institute will be devoted to research, instruction purposes and eugenic practice The practice will be chiefly of a polyclinical nature. On four forenoons and one evening lectures will be held, at which, in cooperation with the referring clinics, physicians and bureaus, heredobiologic investigations, consultations and the rendering of expert opinions will be carried on Eight rooms and a small laboratory (used also for photographic work) are available A number of young women will aid in the securing of information from various sources and in the preparation of genealogical trees For more detailed research four single rooms and four double rooms are provided. In addition to the rooms for the scientific workers, there is an auditorium with 250 seats an assembly room for sixty auditors, and a room for collections and paraphernalia used for demonstration purposes For medical students regular courses of lectures are provided in the first clinical semester Hereditary Biology of Man (three hours a week), the next semester Race Hygiene (likewise three hours a week) in the last clinical semester Clinic for Hereditary Diseases (two hours a week) In addition there will be lectures for auditors of all faculties, that is, for other than medical students

Finally, it should be noted that at these health bureaus government consultation centers for heredoracial research, which may be utilized voluntarily by the people, will be established These consultation centers are obligatory only for persons who are applying for a marriage loan and for persons who wish to settle in the country or desire to make application for citizenship These centers will investigate a person's hereditary antecedents which will include the preparation of a family tree which must go back to his four grandparents, and will comprise also information obtained from members of his family

from hospitals, and from other institutions. For every person a record card must be made out for the archives of hereditary biology. A copy is sent to the bureau of health of the examinee's birthplace, and a second copy to the federal bureau of health. Through the use of all available data in the bureau of health, in the juvenile bureaus, in the courts and in other institutions, it will be possible gradually to complete the archives of hereditary biology and to make them an unerring source of information as affecting families with hereditary defects residing within the limits of the bureau of health. In connection with legal adoption of children, these consultation centers must see to it that only children without hereditary defects are adopted (when the progenitor of the child is known). The consulting physician at these centers must above all, serve as the protector of the family that is free from hereditary defects. He must therefore promote, as far as possible marriages between persons with no hereditary defects, and must advise against a person with grave hereditary defects marrying into a family in which hereditary taints are absent. Another duty of these consultation centers is to dissuade parents who are not ill but who already have one child with grave hereditary defects from having further children.

Changes in the Medical Curriculum and Examinations

As a step in the long expected reorganization of the universities, a new division of the school year, applicable to all Austrian universities, including the medical faculties, has been announced. The regulations will apply to the coming winter semester. The new plan does away with the abnormally short summer semester, which has been only two and one-half months in length. There will be two semesters of virtually equal length: the winter semester, the lectures beginning October 1 and extending to January 31 and the summer semester, the lectures beginning February 15 and closing June 28. The regular period for matriculations for the winter semester is from September 23 to October 15 and for the summer semester from February 1 to February 21. The Christmas holidays will extend from December 19 to January 7 and the Easter holidays from March 16 to April 20. Examinations and conferring of degrees may take place, if desired any time during the vacations, and, after the close of the summer semester, on up to July 15, and also from September 20 on, preceding the opening of the winter semester. Continuation of the clinical hospital service during the vacations, and on Sundays and holidays will be regulated by special provisions. The regulations pertaining to medical examinations, which have been in force since April 14, 1903 have likewise been changed. Beginning with Oct. 1, 1935, the following regulations will be in effect. The three so-called *rigorosen* (rigorous tests) will be retained. In the first *rigorosum* the test in general biology has been omitted so that this examination will consist of tests in physics for medical students (only a theoretical test) chemistry for medical students anatomy, histology and physiology (these four tests being from both the theoretical and the practical point of view). In the second *rigorosum* the test in general and experimental pathology has been omitted. The subjects that remain are pathologic anatomy and histology pharmacology and prescription writing, internal medicine, pediatrics neurology and psychiatry. Pharmacology and prescription writing are treated only theoretically, the other subjects theoretically and practically. Those students who, on Oct. 1 1935, have not yet completed their first (or second) *rigorosum* do not need to be examined in the subjects that have been omitted (biology and pathology) from the *rigorosum* concerned (nor will a previous failure in these omitted subjects have to be made good). The

third *rigorosum* will cover, as before, surgery, gynecology, obstetrics, ophthalmology, dermatology, syphilis, forensic medicine and hygiene. One precondition, however, is that every candidate must furnish evidence that he has heard the clinical lectures on all the subjects of the second and third *rigorosum*. These lectures are made "obligatory," whereby it is hoped to attain an even and thorough training in all the principal clinical branches.

The second part of the examinations regulations concerns the rules that obtain in the event that the candidate fails to pass the tests in all subjects. Formerly any single test in the six subjects comprising the first *rigorosum* might be repeated even more than three times, if the candidate failed in a previous test. Now no more than three further trials in any one subject are permitted and if the candidate fails in two subjects of the first *rigorosum* he will be allowed only two more trials. If the candidate fails in four subjects of the first *rigorosum*, he will be excluded from further study of medicine in Austria. He can never secure the degree of doctor of medicine at an Austrian university, even on the basis of a diploma obtained in a foreign country. Furthermore, any candidate who has not completed the first *rigorosum* within two years of the time he passed the first test will be excluded from further study in Austria. An exception may be made if the candidate can show that the delay occurred through no fault of his (sickness, war). The main purpose of the more severe rules applied to examinations in medicine is that students who have revealed by their repeated failures in tests that they are not adapted to the study of medicine may take up some other profession without undue loss of time. Degrees will be conferred, at the latest, within six weeks of a candidate's passing his last test. If a candidate does not take his degree within the specified time, he may have to wait a long while before a second opportunity will be afforded him.

Prevention of Posterity with Hereditary Taints

The renewed interest that the German sterilization laws have awakened throughout the world in the hereditary transmission of disease induced Prof. Dr. Julius Bauer to deliver a lecture on 'The Prevention of Posterity with Hereditary Taints' before the Akademischer Verein für medizinische Psychologie. The desired goal may be best attained through the sterilization of all persons who are likely to generate posterity with hereditary taints, among which the German sterilization law mentions congenital weak-mindedness, schizophrenia, circular insanity epilepsy, hereditary blindness hereditary deafness grave alcoholism, and many other conditions. Professor Bauer admitted, however, that the goal sought is attained but imperfectly by the sterilization law, because only those persons with manifest defects and not persons with pathologic hereditary predispositions (who are apparently healthy) are held to trial through the operation of the law. This apparently healthy group perpetuates the hereditary defects. On the other hand a far-reaching application of the sterilization law to persons with slight disturbances may effect a loss of valuable hereditary qualities in sterilized persons. It is well known that Beethoven's father was gravely addicted to indulgence in alcohol. The parents of many artists and poets were not quite normal mentally, their sterilization would have constituted a great loss to mankind. A much more ethical and less dangerous (though, to be sure less reliable) method of preventing offspring with hereditary defects is by means of consultations on marriage and possibly prohibition of marriages, particularly with reference to persons with so called recessive predispositions. Especially marriages of relatives in families with recessive hereditary taints should be absolutely prohibited. Through publicity campaigns, a knowledge of the laws of heredity and the resulting responsibilities resting on citizens should become more widespread.

Marriages

JOHN MONTGOMERY ANDREW, Lexington, N. C., to Miss Mabel Winnifred Wain of Granite Quarry, August 25

PAUL MULFORD MECRAY JR., Moorestown, N. J., to Miss Justine Godchaux Eisman of St. Louis, July 6

WILLIAM LEMUEL GRIGGS JR., Saint Charles, Va., to Miss Dorothy Fugate of Clinchport, September 7

THOMAS FINCHER MCDANIEL to Miss Josephine Richardson, both of Atlanta, Ga., June 15

GEORGE BOWERS MANSDORFER to Miss Louise Warfield Hook, both of Baltimore, August 28

ASHELEY CURTIS NORFLEET to Miss Dorothy Edwards, both of Tarboro, N. C., June 22

LAURISTON L. KEOWN, Baltimore, to Miss Gladys May Dykes of Eden, Md., August 30

LEONARD J. MONSON, Hendricks, Minn., to Miss Eunice Johnson of St. Paul, July 27

BRUCE N. WOLFF, Gettysburg, Pa., to Miss Dorothy Seiple of Harrisburg, June 8

CARLO S. SCUDERI to Miss Alice Kathryn Regan, both of Chicago, July 31

ROBERT E. ROCK to Miss Beryl Canfield, both of Minneapolis, June 18

Deaths

Francis Wenger Heagey, Omaha, Columbia University College of Physicians and Surgeons, New York, 1912, associate professor of medicine, Creighton University School of Medicine, and at one time assistant professor of medicine and assistant professor of anatomy, instructor in anatomy at his alma mater, 1915-1916, fellow of the American College of Physicians, president of the Nebraska State Tuberculosis Association, on the staffs of the Creighton Memorial, St. Joseph's Hospital and the Douglas County Hospital, for three years on the staff of St. Luke's Hospital in New York, aged 51, died, August 23, of embolism, one week following an appendectomy

John Ignatius Fanz, Philadelphia, Jefferson Medical College of Philadelphia, 1912, professor of pathology, bacteriology and hygiene, Temple University School of Medicine at various times instructor in anatomy and physiology, and demonstrator in pathology at Jefferson Medical College, and demonstrator in biology at the Daniel Baugh Institute of Anatomy and Biology of the college, on the staff of the Philadelphia General Hospital, aged 44, died, August 26, of heart disease at his summer home in Bozeman, Md.

Harry Wardwell Carey, Troy, N. Y., Johns Hopkins University School of Medicine, Baltimore, 1901, fellow of the American College of Physicians, past president of the Rensselaer County Medical Society, formerly instructor in physical diagnosis and medicine, Albany (N. Y.) Medical College, author of a textbook entitled "Bacteriology for Nurses" aged 60, on the staffs of the Cohoes (N. Y.) Hospital and the Samaritan Hospital, where he died, August 14, of coronary thrombosis

Elbert William Rockwood, Iowa City State University of Iowa College of Medicine, Iowa City, 1895, professor of chemistry and toxicology at his alma mater, and at different times demonstrator in chemistry, and associate professor, first director of the University Hospital, author of "A Laboratory Manual of Physiological Chemistry" and "Introduction to Chemical Analysis for Medical Students" aged 75, died, July 17, of heart disease

Adolph Oscar Loe, Seattle, University of Minnesota Medical School, Minneapolis, 1897, member of the Pacific Coast Surgical Association and the North Pacific Surgical Association, fellow of the American College of Surgeons, past president of the King County Medical Society, member of the state board of medical examiners, on the staff of the Seattle General Hospital, aged 63, died suddenly, July 31, of coronary occlusion.

Charles Naumann McCloud, St. Paul, University of Minnesota Medical School, Minneapolis, 1901, medical director and vice president of the Minnesota Mutual Life Insurance Company, past president of the Ramsey County Medical Society and the Minnesota Academy of Medicine, aged 63, for many years on the staffs of St. Luke's Hospital and the Miller Hospital, where he died, August 13, of tularemia

Thomas Wilbur Bath, Reno, Nev., St. Louis College of Physicians and Surgeons, 1892, secretary of the Washoe County Medical Society, veteran of the Spanish-American and World wars, formerly county health officer, fellow of the American College of Surgeons, aged 70, on the staffs of the Washoe County Hospital and St. Mary's Hospital, where he died, August 11, of acute myocarditis

James Comer Johnston, McAlester, Okla., Fort Worth School of Medicine, Medical Department of Fort Worth University, 1908, member of the Oklahoma State Medical Association, past president and secretary of the Pittsburg County Medical Society, aged 57, on the staffs of St. Mary's Infirmary and the Albert Pike Hospital, where he died, July 26, of carcinoma of the colon

Philemon Emile Hommell, Jersey City, N. J., Bellevue Hospital Medical College, New York, 1894, member of the Medical Society of New Jersey, one of the founders and dean emeritus of the New Jersey College of Pharmacy, Newark, at various times delegate to the U. S. Pharmacopoeial conventions, aged 72, died, August 21, of carcinoma of the rectum

Alfred Woodhouse, Toms River, N. J., Hahnemann Medical College and Hospital of Philadelphia, 1904, member of the Medical Society of New Jersey, president and formerly secretary of the Ocean County Medical Society, on the staffs of the Paul Kimball Hospital, Lakewood, and the Point Pleasant (N. J.) Hospital, aged 56, died, July 27

Lawson Lee Simmons, Greensboro, N. C., University of Tennessee Medical Department, Nashville, 1893, Vanderbilt University School of Medicine, Nashville, 1899, member of the Medical Society of the State of North Carolina, aged 65, on the staff of the Wesley Long Hospital, where he died, July 22, of cancer of the pancreas

Osce Pierce Sweatt, Waxahachie, Texas, Hospital College of Medicine, Louisville, Ky., 1891, member of the State Medical Association of Texas, served during the World War, on the staff of the Waxahachie Sanitarium, aged 66, died, July 27, in the Veterans Administration Facility, Muskogee, Okla.

Frederick Taylor Van Eman, Kansas City, Mo., Kansas City (Mo.) Medical College, 1897, member of the Missouri State Medical Association, past president of the Jackson County Medical Society, served during the World War, aged 64, died, July 21, in the Trinity Lutheran Hospital

Frank W. Bullen, Hibbing, Minn., Rush Medical College, Chicago, 1896, for twelve years member of the school board, coroner for fifteen years, on the staff of the Rood Hospital, aged 65, died, July 21, of cerebral hemorrhage while playing golf at Swan Lake, Pengilly

Harry Clay Boyd, Waynesboro, Tenn., University of Louisville (Ky.) School of Medicine, 1887, member of the Tennessee State Medical Association, past president of the Hardin-Lawrence-Lewis-Perry-Wayne Counties Medical Society, aged 70, died, August 9

Evan Coleman Brock, Columbus, Ohio, Starling Medical College, Columbus, 1904, fellow of the American College of Surgeons, aged 54, on the staffs of the White Cross Hospital and the Mount Carmel Hospital, where he died, August 15, of cerebral hemorrhage

Eugene Yetman Young, Champaign, Ill., Rush Medical College, Chicago, 1903, member of the Illinois State Medical Society, on the staff of the Burnham City Hospital, aged 55, died, July 22, in the Mercy Hospital, of bilateral tuberculosis of the kidneys

Robert Bruce Wilson, Newton Grove, N. C., Kentucky School of Medicine, Louisville, 1889, member of the Medical Society of the State of North Carolina, aged 79, died, July 12, in a hospital at Fayetteville, of chronic nephritis and prostatic obstruction

Michael Manley Waterhouse, New York, Bellevue Hospital Medical College, New York, 1898, member of the Medical Society of the State of New York, veteran of the Spanish-American War, aged 65, died August 21, of carcinoma of the stomach

Mary Fish Fleckles, Brooklyn, New York Medical College and Hospital for Women, 1894, on the staff of the Prospect Heights Hospital, Cumberland Hospital and the Methodist Home for the Aged, aged 71, died, August 15, of heart disease.

Howard Marshall Batson, Mannington, W. Va., Medical College of Virginia, Richmond, 1906, served during the World War, aged 60, died August 10, in the Cook Hospital, Fairmont, of tonsillitis, septic arthritis and mesenteric thrombosis

Harry Herr Smiley ♂ Texarkana, Ark., University of Missouri School of Medicine, Columbia, 1901, fellow of the American College of Surgeons, served during the World War, aged 60, died suddenly, August 20, of coronary thrombosis

Henry Dreer McCormick, Germantown, N. Y., College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1890 member of the Medical Society of the State of New York, aged 69, died, August 26

George L. Rice, McSherrystown, Pa. Washington University School of Medicine, Baltimore, 1873, formerly county coroner and member of the state legislature for thirty six years justice of the peace, aged 85, died, July 15

George Edgar Newby ♂ Hartford, N. C., Jefferson Medical College of Philadelphia, 1900, secretary of the Chowan-Perquimans Counties Medical Society, aged 60, was instantly killed, July 28, in an automobile accident

Franklin M. Leitch, Moscow, Idaho, Homeopathic Medical College of Missouri, St. Louis, 1889, member of the Idaho State Medical Association, formerly health officer of Moscow aged 84, died, August 6, of myocarditis

John Mann ♂ Old Westbury, N. Y., University of the City of New York Medical Department, 1884 aged 77 for many years on the staff of the Nassau Hospital Mineola, where he died, August 19, of heart disease.

Nectar Miriam Kalaljian Fisk, Royal Oak, Mich. Michigan College of Medicine and Surgery, Detroit, 1896 member of the Michigan State Medical Society, aged 59 died August 19, of carcinomatosis

Alexander Wood Brodie, Prince Albert, Sask. Canada McGill University Faculty of Medicine, Montreal Que., 1917 served with the Canadian Army during the World War aged 44, died suddenly, June 13

James Wilton Thurman, Floyd, Va., University of Virginia Department of Medicine, Charlottesville 1883, aged 79 died, July 23, in the University Hospital, Charlottesville, of cerebral hemorrhage

Milton R. Thrailkill, Caldwell, Kan., Northwestern Medical College, St. Joseph, Mo., 1885, aged 72, died August 19 in a hospital at Ardmore Okla. of injuries received in an automobile accident

James Henry Oughton ♂ Dwight, Ill., College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1907 aged 53 was shot and killed by bandits, August 1

John Gordon Love, Hartman Ark. (licensed in Arkansas in 1903), member of the Arkansas Medical Society, on the staff of the Johnson County Hospital Clarksville aged 56 died, July 14

Emil Frederick Baur, Chicago University of Michigan Department of Medicine and Surgery, Ann Arbor, 1892, aged 67, died, August 25, in the Presbyterian Hospital of infarction of the lungs

William H. Melster, Milwaukee, Northwestern University Medical School, Chicago, 1906, member of the State Medical Society of Wisconsin, aged 51 died August 20 of lymphosarcoma.

Frank James Shook, Warren, Ill., Rush Medical College Chicago, 1900, aged 68, died, August 2 in St. Francis Hospital, Freeport, of cerebral hemorrhage and arteriosclerosis

John W. Ross, Cohoes, N. Y., McGill University Faculty of Medicine, Montreal, Que., Canada, 1881 on the staff of the Cohoes Hospital aged 80, died, July 29 of arteriosclerosis

Simeon David Bashore, Palmyra, Pa., Jefferson Medical College of Philadelphia, 1896, served during the World War aged 63, was found dead, August 22, of angina pectoris

Charles Amiot, Montreal, Que., Canada School of Medicine and Surgery of Montreal, 1898 formerly municipal councillor and mayor of Asbestos, aged 61 died, June 13

Bennett Newton Sewell ♂ Boyce, La. Tulane University of Louisiana Medical Department, New Orleans 1893 aged 65 died, July 21, of coronary thrombosis

Edwin Thomas Cundiff, Pittsburgh, Kan., Howard University College of Medicine, Washington, D. C. 1933 aged 28 died, July 27, of a gunshot wound

Arthur Ormsby Nicholson, New York. Cornell University Medical College, New York, 1911, on the staff of St. Vincent's Hospital, aged 49, died, July 22

Frederick Lee Sandel, Columbia S. C., University of Georgia Medical Department, Augusta 1888 aged 70 died August 5, of chronic endocarditis

Austin L. Cleveland, Dallas City, Ill., Bennett College of Eclectic Medicine and Surgery, Chicago, 1906, aged 63, died August 1, in Rockford, of pyemia

Charles Lee Behrns, Alice, Texas, Tulane University of Louisiana Medical Department, New Orleans, 1903, aged 66, died recently of paralysis agitans

Allan Sterling, Fredericton, N. B., Canada McGill University Faculty of Medicine, Montreal, Que. 1897, aged 62, died May 26 of angina pectoris

Rollin Henry Knowles, New York, Starling Medical College, Columbus, 1881, aged 79, died, August 13, of angina pectoris and coronary occlusion

Sterling Price, Fort Worth, Texas, Hospital College of Medicine Louisville, Ky., 1893, aged 69, died, July 31, of endocarditis and hypertension

Earl Webb Smith, Phoenix, N. Y. Syracuse University College of Medicine, 1885 aged 76, died, July 7 of coronary occlusion and arteriosclerosis

Noah Rouse ♂ Carson City, Nev., George Washington University School of Medicine, Washington, D. C., 1924, aged 36 was drowned, August 3

Max Myers Fields, Dante, Va., Medical College of Virginia Richmond 1928, aged 30, died, June 17, in the Clinchfield Hospital, of pneumonia

George Walker Davidson, Cincinnati, Trinity Medical College, Toronto, Ont., Canada, 1892, aged 66 died in July, at Mariposa, Ont., Canada

Joseph Lauffer Sowash, Irwin, Pa., Western Pennsylvania Medical College, Pittsburgh 1897, aged 65, died, July 28, of carcinoma of the lung

George W. Ressler, Valley View, Pa. Jefferson Medical College of Philadelphia, 1884, aged 71, died, July 24 in a hospital at Philadelphia

George Dudley Riggs, Bristol, Va. Meharry Medical College Nashville, Tenn., 1926, served during the World War aged 46, died, July 29

Dallas Texas Odell, Christopher, Ill., Keokuk (Iowa) Medical College, College of Physicians and Surgeons 1901, aged 55, died, July 30

Jules Fred Constantin, Roberval, Que., Canada Laval University Faculty of Medicine, Quebec, 1887 aged 69 died May 28, of angina pectoris

Edward F. Suhre, Forest, Ind., Central College of Physicians and Surgeons, 1897 aged 66, died, August 12 of cerebral hemorrhage

Mary Florence Lemmon, Cadiz, Ohio, Homeopathic Hospital College, Cleveland 1893, aged 75, died, July 23 of cerebral hemorrhage.

William D. Sydnor, Hamilton, Va. (licensed in Virginia in 1899), aged 59 was found dead in bed, August 8 of cirrhosis of the liver

Taylor W. Scott, Stafford, Kan., University of Louisville (Ky.) School of Medicine 1881, aged 75 died July 12, of chronic nephritis

Robert Roy McClenahan, Port Nelson, Ont., Canada University of Toronto Faculty of Medicine 1912 aged 44 died, July 19

Gavin Steel Scott, Ramona, Calif. University of Glasgow Medical Faculty Scotland, 1884, aged 74 died July 27, of pneumonia

Forrest Snowden King ♂ Muskogee Okla. Western Pennsylvania Medical College Pittsburgh, 1907 aged 55 died, August 5

Henry Wolin ♂ New York, Long Island College Hospital Brooklyn 1915, aged 51, died July 18, in the Mount Sinai Hospital

John George Tapper, Elgin Ill. Rush Medical College, Chicago 1882 aged 82 died, September 10 of chronic myocarditis

George W. Crum, Arenzville Ill. St. Louis Medical College, 1874 aged 86, died August 7 of coronary thrombosis

Douglas Corsan, Fernie B. C. Canada, McGill University Faculty of Medicine, Montreal, Que., 1885 died, July 13

Henry J. Trachman, Windsor, Calif., Baltimore University School of Medicine, 1900, aged 64, died July 14

Stillman Marion Benner, Campbell Calif., Rush Medical College, Chicago, 1879, aged 81, died, July 26

William R. Loftin, Grubbs Ark. (licensed in Arkansas in 1903) aged 70, died, July 7

Bureau of Investigation

MST TREATMENT FOR RHEUMATISM

Another Fraud Debarred from the Mails

Mortin Products of Kansas City, Mo., and Denver, Colo. has been selling a neo-cinchophen-amidopyrine nostrum as a cure for rheumatism under the names "MST Treatment" and also "Mortin's No 1" and "Mortin's No 2". On August 31, 1935, the Postmaster General, having been satisfied that the Mortin Products concern was swindling the public through the United States mails, issued a fraud order closing the mails to the outfit.

The memorandum of Mr. W. E. Kelly, Acting Solicitor for the Post Office Department, to the Postmaster General, embodying the finding of facts and recommending the issuance of a fraud order, gives some interesting data on this swindle. According to the memorandum, Mortin's Products was promoted by three men, W. H. Menzel, C. O. Butler and Walter L. Kight, the first two operating from Kansas City, Mo., and the last from Denver. The business was started, however, in Oakland, Calif., and was an attempt to carry on a business that had been conducted from Houston, Texas, under the name of Mortin Products. Menzel and Butler had been employed by the Mortin Products concern, which sold an alleged cure for rheumatism under the name "MST" ("Martin's Specialized Treatment"). In September, 1934, the promoters of the Houston outfit were cited by the postal authorities to show cause why a fraud order should not be issued against them. At that time the Mortin concern filed with the Post Office an affidavit stipulating that the business had been absolutely discontinued and abandoned and would not be resumed and the Postmaster at Houston was directed to return to the writers all letters addressed to Mortin's Products, stamping on the envelopes "Out of Business".

At this point it is worth noting that cases of acute yellow atrophy of the liver, some fatal, due to the use of MST (which first was a cinchophen-amidopyrine product and later a neocinchophen-amidopyrine preparation) had begun to accumulate.

Menzel and Butler had in the meantime had trouble with their employers, Mortin Products and they adopted the name Mortin Products, copied the literature and advertising of Mortin Products and attempted to duplicate the Mortin Products preparation. They started business in Oakland, California, but the promoter of Mortin Products went to Oakland and secured an injunction restraining Butler, Menzel et al., from operating under the name Mortin Products. Butler and Menzel thereupon removed to Denver and Kansas City and continued the operation of the scheme with advertising matter copied from that formerly employed by Mortin Products.

According to Mr. Kelly's memorandum, also both Kight and Butler had formerly been employed by a Chicago concern that sold a nostrum for rheumatism. Neither Kight, Butler nor Menzel are physicians, pharmacists or chemists—in fact, Kight is said to have been an oil-tank wagon driver and Butler to have been in the shoe business.

From a letter received from the Board of Medical Examiners of the State of California it appears that W. H. Menzel had also been a field representative for another fake rheumatism remedy, the Nue-Ovo Laboratories of Portland, Ore. (Nue-Ovo was declared misbranded under the National Food and Drugs Act in Notice of Judgment 16390, an abstract of which was published in this department of THE JOURNAL, Aug. 30, 1930.)

The Mortin nostrum was described as a 'scientifically compounded medicinal preparation for rheumatism' that was "a new and recent discovery, not like so many so-called cures reputed to have been discovered fifty or one hundred years ago." The Mortin preparations were analyzed for the postal authorities by the chemists of the Food and Drug Administration. "Mortin's Product No 1" was found to be tablets each weighing about four grains and containing over one grain of neocinchophen and slightly under one grain of amidopyrine to the tablet the balance of the tablet being made up of milk

sugar and chalk. "Mortin's Specialized Preparation No 2" had essentially the same composition. With this mail-order treatment there was also sent a bottle of "MIT" ("Mortin's Intestinal Tonic," an imitation of "Martin's Intestinal Tonic") which the victim was told to use when a laxative was required. Analysis showed the tablets to contain plant extractives, including asafoetida and emodin-bearing (laxative) drugs, ginger, red pepper and strychnine.

According to the advertising of the Mortin outfit, the laws of the United States prohibit any one but a licensed physician from diagnosing or prescribing for any ailment. This statement, of course, is, unfortunately, wholly false. The Mortin advertising went on to state further that the concern had 'one of the best physicians on the Pacific Coast serving as a "chief of staff physicians".'

In addition, the Mortin quacks sent to each prospective victim a questionnaire containing twenty-nine questions that were to be answered by the sufferer. It is brought out by Mr. Kelly in his memorandum that the questionnaire was not examined by any physician and the representations with respect to the "staff physicians" were a fraudulent pretense employed by the promoters to lend respectability to their scheme. Kight, who operated the Denver branch of this fraud, informed the Post Office inspector that Dr. A. O. McMichael of that city was the company's physician there.

The files of the Bureau of Investigation show that a few years ago McMichael was exploiting a "patent medicine known as 'Dr. McMichael's Allgland With Radium'." This preparation was advertised under fraudulent claims and was declared misbranded under the National Food and Drugs Act. It was the subject of a brief article in this department of THE JOURNAL July 23, 1927. According to the records of the American Medical Association, Americus O. McMichael was born in 1863, claims a diploma from Drake University College of Medicine, 1894 and is licensed in Iowa, Missouri and Colorado. In 1924 McMichael's name was given as the director of another nostrum outfit, the Carnotite Gland Extract Company, in 1920 as president and medical director of the Radioactive Chemical Company of Denver and in 1925 as "Medical Director" of the Allfood Laboratories.

Acting Solicitor Kelly's memorandum to the Postmaster General stated further that when the Post Office inspector questioned C. O. Butler in Kansas City with respect to the representations as to staff physicians he claimed that all questionnaires received at Kansas City were turned over to Dr. McMichael at Denver, although Kight, in charge of the Denver office, had admitted to the inspector that none of the questionnaires were turned over to McMichael.

In their answer to the charge by the postal authorities Menzel, Butler and Kight stated that they maintained a registered and licensed physician to examine the questionnaires, make laboratory analyses and prescribe diet routine and other therapy wherever indicated, and they submitted an affidavit executed Aug. 15, 1935 by Lewis J. Greenfield, M.D., of Denver, in which Dr. Greenfield averred that he is a "Staff Physician for Mortin's Products Distributors." However, the affidavit made no statement as to when Dr. Greenfield was employed, nor did it indicate that he had ever examined any questionnaires or given any advice. The files of the American Medical Association show that Dr. Lewis J. Greenfield was born in 1896, holds a diploma from the "diploma mill" St. Louis College of Physicians and Surgeons, 1925, and a Colorado license issued the same year. Dr. Greenfield is, of course, not a member of the American Medical Association.

Solicitor Kelly states that the evidence indicates that after the Mortin quacks found they were under investigation by the postal authorities, the arrangement with Greenfield was made so as to give them something to present to sustain the advertised claim regarding "staff physicians." The postal authorities reported further that the same tablets were sent to all purchasers, and the same printed instructions with respect to diet, hygiene and exercises were also sent, regardless of the cause of trouble or the condition of the patient. Mr. Kelly summed up his findings as follows:

"The evidence shows that the preparations are merely pain killers and nothing more and that respondents' representations to the contrary are knowingly false and fraudulent. The evi-

dence shows that the preparations will not reach directly to the source of rheumatic infection, cleanse the blood, regulate and tone the stomach, liver, kidneys and bowels, and that it is false to represent that even though a person may not be suffering from rheumatism these preparations are incomparable system builders, blood purifiers, and restorers of normal bodily functions"

As a result, Mr. Kelly recommended the issuance of a fraud order, which, as already stated, has gone into effect debarring this swindle from the United States mails

Correspondence

HYPERGLYCEMIA

To the Editor —In the article by Dr. Herman O. Mosenthal on "Hyperglycemia: Evaluation in the Treatment of Diabetes," in *THE JOURNAL*, August 17 the statement is made by him and most of those who discussed the paper that diabetes is a contributing factor in the causation of arteriosclerosis. I believe Dr. Joslin is the most important sponsor for this view. It is rather curious that in the study of arteriosclerosis most observers have overlooked a rather simple observation which completely disproves any metabolic origin in the causation of arteriosclerosis, namely, the complete independence in the incidence of arteriosclerosis between the general and pulmonary circuits (Moschowitz, Eli. *The Cause of Arteriosclerosis Am J M Sc* 178:244 [Aug.] 1929). A false perspective is given to the study of human arteriosclerosis when observations are confined, as is conventionally done, to the aorta and its branches. If, however, observations on the aorta and the pulmonary artery are made it will be quickly realized that simultaneous arteriosclerosis in the two circulations is the exception rather than the rule, so that if arteriosclerosis is found in the aorta the lesion is not necessarily present in the pulmonary artery and vice versa. Early anatomic arteriosclerosis is almost universal in individuals in the third decade of life and increases in intensity and distribution as one passes to the senescent years even when the blood pressure remains normal (decreased arteriosclerosis) whereas arteriosclerosis in the pulmonary artery is almost exclusively associated with conditions in which an increased pressure in the pulmonary circuit can be predicated. These are, in the order of frequency: mitral stenosis, pulmonary emphysema, extensive pleural adhesions and fibrosis of the lung, patent foramen ovale, and communications between the right and left sides of the heart. Pulmonary arteriosclerosis is therefore entirely independent of age and sex, I have observed it not uncommonly even in infants with congenital heart disease. The relation of intravascular tension in the causation of arteriosclerosis therefore is vital in the study of the problem. If diabetes were the cause of arteriosclerosis, one would expect as great an incidence of arteriosclerosis of the pulmonary artery as of the aorta, because the same blood bathes the two circulations but even a casual inspection of autopsy material will show that pulmonary arteriosclerosis never occurs in diabetes unless such disease as I have referred to is associated.

Many writers have confused arteriosclerosis with the lipid imbibition of the aorta witnessed in nurslings on a high fat diet, in advanced diabetes and nephrotic syndromes associated with hypercholesteremia, and in the experimental arteriosclerosis initiated by Amitschkow and his school produced by excessive cholesterol feeding. This is the lesion that Leary in the same issue of *THE JOURNAL* calls "atherosclerosis." I believe that such a conclusion is not justified first because such lesions unless too far advanced are regressive; secondly, because such lesions are not limited to the arterial tree but are distributed as well to the intima of the veins and to the reticulo endothelial system; thirdly, because the pulmonary artery and the aorta are simultaneously involved and fourthly experimental arterio-

sclerosis is produced only under conditions entirely unphysiologic. Human arteriosclerosis histologically presents all the earmarks of a reaction compensatory to intravascular tension. It represents an involutionary process. It is generally overlooked that hypertension is not a new insult that has entered the organism but represents an exaggeration of a normal physiologic function, namely, intravascular tension. Therefore, normal intravascular pressure will also cause arteriosclerosis, given a sufficient period. That is why arteriosclerosis is a normal phenomenon in the greater circulation in the senescent years. The reason it is absent in the pulmonary artery except under the conditions I have mentioned is that the normal intravascular pressure in the pulmonary artery is one-sixth that of the aorta.

While the complete independence in the incidence of arteriosclerosis in the pulmonary and aortic arteries furnishes the most obvious argument against the metabolic origin of arteriosclerosis the absence of arteriosclerosis in most cases of juvenile diabetes is additional evidence.

To my mind all evidence seems to show that arteriosclerosis is the cause of diabetes rather than the reverse. I have tried to show that arteriosclerosis is only a localized form of vascular sclerosis and that pathologically and pathogenically there are lesions of the capillaries, veins and the lining of the heart chambers that are precisely comparable. When diabetes occurs in arteriosclerosis the inference is that the capillaries of the islands of Langerhans are affected. Why in arteriosclerosis the clinical brunt should be on one or the other organ is a problem that awaits a solution.

ELI MOSCHOWITZ, M.D., New York

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address but these will be omitted on request.

ALOPECIA AREATA

To the Editor —My son now 12 years 11 months old has had alopecia areata since he was 5 years old. His height is 5 feet 6½ inches (168 cm.), his weight 130 pounds (59 kg.). He is in excellent health and has never had any serious illness. Physical examination is entirely negative except for alopecia. The basal metabolic rate is 0. The blood count is normal. At times the alopecia becomes almost complete then hair begins to fill in but never completely—always one or two patches of alopecia remain. At present the alopecia is extensive. He has made rounds of many dermatologists with but little success. Kindly discuss in *Queries and Minor Notes* (1) etiology (2) prognosis especially what may be expected at puberty and (3) treatment. Has anterior pituitary any value? If so what untoward effect on the growth of the skeleton? The patient is very sensitive about his trouble and spends much time worrying about the eventual outcome. Kindly omit my name.

M.D., Colorado

ANSWER—1 The etiology of alopecia areata is still obscure after many years of research. The chief theories are (a) the trophoneurotic, (b) focal infection, (c) syphilis, (d) heredity, (e) contagion and (f) the endocrine sympathetic theory.

(a) Much evidence favors the influence of nervous instability, trauma affecting the nervous system, or reflex nervous influence on the occurrence of alopecia areata. The experiments of Joseph Nivelli and others most recently of Beeson and Pickett (*Experimental Alopecia, Arch Dermat & Syph* 28:53 [July] 1933) on cats produced localized patches of alopecia within a month. There has been some argument that these are not patches of genuine alopecia areata but the fact remains that they do resemble alopecia areata in many respects. The literature is full of references to cases of alopecia areata occurring after physical trauma to the nervous system and shock or nervous disturbances of various kinds.

(b) Jacquet's theory that alopecia areata is one of the symptoms of a general condition comparable to the molting of animals is not now considered seriously, but his emphasis on reflexes from the teeth, eyes and so on is still to be considered in some cases of the disease. Chipman's theory of focal infection as a cause of alopecia areata has not received much support but it also should be kept in mind.

(c) Syphilis is considered by the French authorities as one of the most significant factors in the etiology of alopecia areata. Outside of France this relation is not stressed. Undoubtedly in rare cases, syphilitic alopecia resembles alopecia areata to some extent. If syphilis has a relation to real alopecia areata it is probably an indirect one, an influence on general resistance or perhaps a more direct influence through the nervous system.

(d) The evidence in favor of heredity in alopecia areata is considerable. It has in many instances occurred in several members of a family. This may be explained as due to similar endocrine disturbances or anomalies in the family or due to contagion.

(e) The latter has always been stressed in the etiology of this peculiar disease. Epidemics have been reported in England, Germany, France and Italy. While some of them have been successfully explained away as alopecia due to impetigo or to neurotic rubbing, it seems that some of the epidemics have been composed of genuine cases of alopecia areata. If alopecia areata is a distinct disease due to a single cause, and its symptomatology and course favor this opinion, the contagion must be a weak one able to gain a foothold only in a few persons of low resistance, or as that of herpes simplex—able only now and then to become strong enough to manifest itself. Its trait of recurring sometimes at regular intervals, in other cases erratically, strengthens the analogy.

(f) The role of endocrine disturbance in the etiology of alopecia areata is based chiefly on the occurrence of the disease with vitiligo, scleroderma, acromegaly, exophthalmic goiter, ovarian dysfunction, adiposogenital dystrophy and other symptom complexes considered of endocrine origin. The microscopic observation that the primary change in alopecia areata is disturbance of pigment lends support to the relation with vitiligo.

Recently Hocker has reported a case of alopecia areata in a girl with irregular menses, with long limbs and large hands and feet, who evidenced, in his opinion, lack of ovarian secretion and an overabundance of the anterior pituitary hormone. She improved both in menstrual regularity and in hair growth on the administration by mouth and subcutaneously of estrogenic substances, but recurrences appeared and after three years' treatment she was suffering another recurrence in spite of energetic treatment (Hocker, H. *Hormonbehandlung einer kreisförmigen später vollkommenen Haarlosigkeit [Alopecia Areata] des Kopfes, Med. Klin.* 30 603, 1934). Others report similar temporary benefit. No evidence of relation to the pituitary gland has been obtained. There is a form of alopecia seen in some cases of pituitary deficiency, but it does not resemble alopecia areata.

2 The prognosis of alopecia areata is good in most cases. Even when the alopecia becomes generalized, the chances of recovery are fair if there is a growth within two years of the onset. After two years without growth of hair the prognosis is not favorable. However, recovery has been known to occur after twenty and thirty-five years of alopecia. The prognosis is best in children, "in whom the disease ceases with development" (Galewsky, in *Handbuch für Haut- und Geschlechtskrankheiten*, Berlin, Julius Springer 13 290, 1929). This is the only reference found to the chance of improvement at puberty.

3 First, search should be made for focal infection or any disturbance of the teeth, eyes or ears that might be causing reflex irritation. The patient should be studied for indications of nervous disturbance or endocrine dysfunction. There is little evidence in favor of treatment with anterior pituitary. There is no experimental evidence that the anterior pituitary or lack of it has anything to do with alopecia areata. In one case moderate improvement occurred during a long course of such treatment. The sister of this patient took the same treatment without benefit. Both had total alopecia. The brother, after about one year of rest, has a recurrence in his sparse scalp hair. The disease is following a typical course and there is grave doubt whether anterior pituitary was of any benefit. Many patients have taken it for long periods without benefit. No effect on the skeletal development of children at puberty has been noted.

General measures to improve resistance are important. Daily salt baths or cold douches are well thought of. General ultraviolet baths may be found helpful, especially in winter. Medication as indicated by any general deficiency or disease should be supplied.

Locally, daily epilation of the loose hairs in the border of the lesions is recommended, followed by a stimulating antiseptic lotion, as red mercuric iodide 1:5,000 in 50 per cent alcohol. Once a week or oftener, according to the reaction, each spot should be treated with ultraviolet rays or an irritant chemical to the point of sharp irritation enough to cause exfoliation. Graded strengths of cresol in alcohol or a mixture of phenol 1 part and lactic acid 4 parts or of equal parts of

chloral hydrate, tincture of iodine and phenol, are among the best chemicals although each dermatologist has his favorite.

If such rough treatment fails, even after long use, the irritants may be stopped and x-rays given, one-eighth skin unit once a week or once in two weeks for three treatments. Irritants should not be reapplied for three weeks after the final dose. Care must be taken to avoid overlapping of exposures, best accomplished by sheet lead or lead rubber protection applied close to the head.

Nothing in this is new and it is probable that the patient under discussion has had all of it at one time or another, but persistence is a virtue in the treatment of alopecia areata, if it is indicated anywhere.

POSSIBLE PSYCHONEUROSIS WITH SUSPECTED HYPERTHYROIDISM

To the Editor—I have under my care a woman aged 32, weight 113 pounds (51 Kg.), who complains of a somewhat tight feeling in the right side of the neck, mucous shreds in the feces flakes in the urine, and a tightening sensation in the bladder after urination. She complains also of soreness when the abdominal aorta is rolled under the palpating fingers, this soreness traveling down the sacrum. She was married at 22 and had her first child seven years ago. Delivery was normal. She always has felt jittery or nervous; there is no evidence of mental or emotional instability. In 1930 the appendix was removed, the uterus suspended to the anterior abdominal wall and the cervix cauterized. The menses have always been normal of the twenty-eight day type (four days) with moderate bleeding prior to and after the operation. She was told by several physicians that she had a goiter and that it would have to be removed before her symptoms would improve. The eyes are normal. There is no facial tremor. The eyes follow well. The tongue protrudes in the midline. Physiologic enlargement of the thyroid is present (struma). The chest and heart are normal. The pulse always runs around 110 to 130 when the patient is up and around 80 while she is asleep and 100 when she is quiet but not asleep. The blood pressure remains around 186 systolic, 110 diastolic and comes down to 160/100 on vasodilator drugs. The abdomen is normal except for various elusive tender spots which are never really constant. Pelvic examination reveals a very dry introitus and vault with much white cheesy material lining the mucous walls. The cervix is normal but the uterus is distinctly atrophic and infantile. The patient has had all sorts of hormone therapy, including protracted courses of antuitrin S with some benefit, theelin and all the others. The rectum is very dry and baggy like, and the rectal folds seem to be abnormally large. The Kahn reaction is negative and laboratory work gives negative results. Including the urine. She has taken compound solution of iodine in the past without result. In spite of all therapy she has her ups and downs, worries a great deal about herself and wonders whether there will ever be any change in her condition. She wakes up at 4 a. m. (hears the passing milk train) and then cannot go back to sleep. Four basal metabolic tests give from plus 4 to plus 14. Do you feel that a subtotal thyroidectomy is indicated? Have you any suggestions as to further treatment? At present she is receiving phenobarbital and sodium nitrite by mouth. According to Crile the thyroid condition (exophthalmic) can be cleared up by sympathectomy. Would it be logical in this case? The patient is rather anxious to have something done to relieve the condition. Your analysis and suggestions will be appreciated. Please omit name.

M. D. Illinois

ANSWER.—The bizarre, disconnected symptoms of which this patient complains suggest a functional disturbance not associated with organic disease. Patients with such complaints are frequently encountered and are often the source of great anxiety to their physicians. During the course of their management medication of all kinds—drugs, endocrine products, compound solution of iodine, sedatives and such—are tried but uniformly without real benefit. Operations, most frequently operations on the pelvic organs, the ductless glands or the abdominal viscera, may have been done but with no more success.

In the present instance a diagnosis of severe psychoneurosis and moderate hypertension is suggested and is probably correct. These two conditions may be related or may be independent of each other. The hypertension should not be taken too seriously. With time and a fair degree of control of her psychoneurosis the blood pressure may well drop to a lower level. In the light of our past knowledge of hypertension, little effect may be expected from specific medication directed toward its control and, conversely, much may actually be effected in lowering the patient's blood pressure if and when her psychoneurosis is controlled.

Patients of this type differ greatly and must be treated individually. They have but one feature in common, a functional basis for their disability, the manifestations of which may be as different in two individuals as their personality. Effective management, therefore, requires resourcefulness and individualization on the part of the physician. The sensible family physician can do much in the care of these psychoneurotic patients. He should endeavor to instill confidence and eliminate fear and should encourage the patients to disregard their imaginary disabilities by constant mental training and direction, in most cases such management will result in a material improvement of their condition. Time, perseverance and a sympathetic under-

standing are essential. Certainly the family physician occupies a strategic position in the care of these patients that may overbalance the advantages possessed by the more highly trained psychotherapist in the management of an individual case.

In the present instance it is noted that the patient is underweight and probably is undernourished. She has abdominal complaints and signs suggestive of "mucous colitis" and she is worried about the state of her health. Such accessory conditions are incidental to the underlying functional disturbance. Reassurance as to the absence of organic disease and a sensible nutritious diet probably would accomplish much in building up her physical condition. Drugs are not advised and may be harmful.

As to the specific questions asked: 1. A subtotal thyroidectomy is not advised and probably would only do harm. 2. Sedative drugs, such as phenobarbital, only tend to aggravate the condition. Healthful, outdoor physical exercise, inducing a natural demand for rest and sleep, probably would accomplish more in the individual case. 3. In the light of our present knowledge, sympathectomy is not indicated and if done in the present instance would only add to the patient's hardship.

CHRONIC COLITIS IN A CHILD

To the Editor—A boy, aged 7 years, who to general inspection appears to be a normal well-nourished child and who has had the usual diseases of childhood but otherwise has had no illness of any consequence began to have a looseness of the bowels beginning at the age of about 2 weeks. This sometimes borders on a diarrhea for days at a time, with inability at all times to control the movement of the bowel when the desire to stool appears. The blood count and urinalysis give negative results. An examination of the stool does not reveal the presence of any parasites or ova, no occult blood or blood cells are found. There is considerable mucus, and a moderate number of pus cells. Sometimes the stool contains copious quantities of mucus but at no time has the mother found evidence of blood or a dark stool. The stools are usually brown or brownish yellow. The child was nursed by his mother and has since had a normal appetite, and general examination reveals normal health. Rectal examination discloses a sphincter muscle of normal tone and proctoscopic examination reveals a red and congested mucosa for a distance of about 5 inches up in the bowel, but otherwise no bowel or rectal disorder. I should appreciate a diagnosis and suggestion for treatment. Please omit my name.

M D Nebraska

ANSWER—There appear to be two factors involved in this case: a looseness of the bowels since the child was 2 weeks of age and an "inability at all times to control the movement of the bowel when the desire to stool appears." These two conditions are perhaps related in this case but not necessarily so. From a description of the case, the stool containing copious quantities of mucus, the boy apparently has a chronic colitis of some sort, somewhat corresponding to the adult condition loosely referred to as mucous colitis. This term is merely a symptom complex of varied etiology. In this particular case infectious causes of colitis such as amebic and bacillary dysentery should be and apparently have been excluded by proper bacteriologic examination of the stools. Such conditions as ulcerative lesions and polyps have been eliminated by the absence of blood in the stools. Celiac disease is ruled out by the early age of onset, the well-nourished appearance and the normal appetite of the child. It might be well, however, to determine the fat content of the stools. The absence of attacks of pain or "colic" tends to exclude a chronic appendicitis, a Meckel's diverticulitis or congenital adhesions about the intestine as reflex causes of the condition. However, a complete gastro-intestinal roentgen study with barium sulphate might possibly reveal something.

At least two possibilities have not as yet been excluded. An allergic reaction of the intestine to certain foods must be seriously considered, especially if there is an allergic family history and other manifestations of allergy in the boy, such as asthma, urticaria, hay fever or transient rhinitis. A diet diary kept by the parents might furnish a clue as to the offending food, or complete skin testing with food allergens might be done.

A congenital neurogenic dysfunction of the colon must be considered, analogous to neuromuscular dysfunctions of the bladder in some children. The two conditions are at times associated. If the child has frequency of urination, anuresis or incontinence of urine the suspicion would be strengthened. Occasionally incontinence may be associated with a spina bifida occulta. A roentgenogram of the lumbar and sacral spine would be indicated. In such conditions incontinence may be associated with normal tone of the external sphincter, as in this case. Because of the diarrhea, the patient may know when his bowel is going to act but cannot retain control for any length of time. Another possibility is that although the loose stools have a physical basis the incontinence may result from a behavior problem, i.e., a continuance or reversion to

infantile habits in an attempt on the part of the child to gain something or to keep himself in the limelight.

The therapy consists in finding the etiologic factor or factors and eliminating them if possible: if food allergy, avoiding the offending foods. If the incontinence results partly from a social maladaptation, proper psychotherapy should be instituted similar to that used in an analogous enuresis, efforts being made especially to impress on the boy that he is no longer a baby and could control himself if he really wanted to.

Symptomatic treatment should be directed toward diminishing the hyperperistalsis by feeding a bland diet, purged foods with no roughage, giving antispasmodics, as atropine, and astringents, bismuth subnitrate and tannates. Occasionally absorbing substances, as kaolin or charcoal, might be of value. Possibly astringent enemas of 1 per cent tannic acid might help.

FEVER OF UNKNOWN ORIGIN

To the Editor—I would appreciate suggestions as to further diagnostic and therapeutic measures that I may take regarding a white woman, aged 21 who has headache and vomiting as the principal symptoms both of unusual duration. The father died of pulmonary tuberculosis, her mother and one half sister are living and well. The patient had measles, pertussis and pneumonia in childhood with uneventful recovery. She has always been thin but was rarely ill until two years ago. Menstruation began at 14, scanty and irregular. The present illness began with what was thought to be influenza in April 1933. She improved slowly until May 1933 when she fell and fractured the right ninth rib. The chest was strapped with adhesive plaster. Recovery was satisfactory. In July 1933 she began to have headache and some fever which rarely was above 100 with slight loss in weight. She was admitted to a hospital where a diagnosis of atypical typhoid was made. A roentgenogram of the chest showed a healed fracture of the ninth rib. There was no evidence of tuberculosis or other abnormality. After one week in the hospital the patient's temperature became normal and remained so until her discharge four weeks later. One week after admission the patient complained of headache and began vomiting. This continued until her discharge. She continued to vomit, complained of headache and still had a low grade fever. She was again admitted to the hospital in September 1933 and was given numerous hypodermoclyses of dextrose and saline solution to control the vomiting and dehydration. A gastro-intestinal series after a barium sulphate meal revealed hypermotility of the stomach, cardiospasm and slight six hour retention. No ulcer was seen. The gallbladder after intravenous injection of dye was normal. She stayed in the hospital three months had headaches and vomiting the whole time and was then allowed to come home under the care of a physician who treated her with diet, antiemetics, sedatives and rest in bed until February 1934 when she came under my care. The patient is well developed but emaciated and very dehydrated. The temperature ranged between 98.6 and 101 from March 1934 to March 1935. The head, eyes, ears, nose, throat and neck are normal. There is no thyroid enlargement. The chest is flat with a rachitic rosary; expansion is good. The lungs are apparently normal. The breasts are small and atrophic. The heart rate is constantly above 100 and is regular in rhythm with no enlargement, murmur or other abnormalities. The abdomen is sunken; there are no masses or tenderness but the patient complains of epigastric discomfort. Vaginal examination has not been done. The pupils are equal and react to light and in accommodation. The knee jerks are slightly hyperactive and equal. The Romberg, Babinski, ankle clonus and Kernig signs are all negative. The superficial abdominal reflexes are normal. Skin sensation is apparently normal over the whole body. I tried all the usual drugs to relieve vomiting: then a liquid diet and then thick foods. After having no success I inserted a Levine tube into the duodenum. Since then I have had the patient take milk, eggs, cod liver oil and orange juice and other liquids. She continues to vomit but does not vomit food. She has been fed by this method almost exclusively for about ten months. The vomiting has never been of a projectile type. Kindly omit name.

M D, Tennessee

ANSWER—The determination of the causes of fever of unknown origin is one of the really difficult problems of internal medicine. In a series of 173 patients discharged from the Peter Bent Brigham Hospital in whom no diagnosis of the cause of the fever was made at the time over a period of about sixteen years, in seventy-eight a definite diagnosis was never made (Alt, H. L., and Barker, M. H. *Fever of Unknown Origin*, *THE JOURNAL*, May 10, 1934, p. 1457). In the twenty-three in whom eventually a diagnosis was made, some form of tuberculosis was ultimately diagnosed in six, valvular endocarditis in six, and malignant conditions in various parts of the body in several cases. It is interesting to note that, in two patients whose temperature reached 104, syphilis was diagnosed on a therapeutic test in one and malaria in another. Not mentioned in this list are cases of undulant fever in which agglutination tests are important for diagnosis. These cases may continue for several months or a year or more. More recently some writers have called attention to amebiasis as a possible cause of fever of unknown origin, even in the absence of diarrhea. If repeated stool examinations, including stool cultures are negative, the Arnold modification of the Craig complement fixation test for amebiasis might be tried. Blood cultures should be frequently repeated and the heart must be repeatedly exam-

ined for endocarditis. Repeated urine examinations are indicated for pyelitis, which might be closed at the time of one of the urinalyses.

Intravenous injections of dye for the determination of some form of renal lesion should be made. Roentgen examination of the long bones in a search for Hodgkin's disease, which involves the periosteum, is indicated. The form of treatment will depend entirely on the ultimate diagnosis. In the meantime, supportive and tonic measures as are being used now should be continued.

ESSENTIAL HYPERTENSION WITH ENCEPHALOPATHY

To the Editor—I wish to inquire about the pathogenesis of epileptiform seizures in arteriosclerotic patients. I have in mind a woman aged 48 until recently a school teacher weighing 174 pounds (79 Kg.) For five years she has presented such signs and symptoms of arteriosclerosis as frequent severe headaches, vertigo, insomnia, irritability, hypertension (averaging around 190 systolic, 100 diastolic), retinal hemorrhages (October 1932) sufficient to cause blindness in the right eye, a high degree of sclerosis of the retinal vessels on ophthalmoscopic examination and an occasional trace of albumin in the urine. In December 1933 she had an intensely severe headache followed in a few hours by a severe epileptiform seizure lasting around five minutes. The patient was stuporous for nearly two days following this and cannot recall events that took place from the onset of the headache to about two days after. The spinal fluid was under moderately increased pressure and a lumbar puncture seemed to relieve the headache and aid in the patient's recovery at that time. She remained very weak for several months but gradually recovered her strength. At present she presents on physical examination essentially the same condition that she did two years ago. At times she feels quite well. Was I justified in giving the relatives of this patient a decidedly unfavorable prognosis? In *Steven's Practice of Medicine*, page 713, it states: "Rarely arteriosclerotic patients suffer from typical epileptiform seizures or stuporous states which are apparently not due to complete vascular occlusion by thrombosis or embolism to heart block and the Adams Stokes syndrome or to uremia but to the vascular changes themselves. I am curious to know something more definite about these vascular changes and particularly why they should cause the convulsions at one time and not subsequently, considering the progressive nature of the disease." Please omit name.

M D Ohio

ANSWER.—We prefer to designate this a case of essential hypertension with "hypertensive encephalopathy." The latter syndrome is well described by Oppenheimer and Fishberg (*Arch Int Med* 41:264 [Feb.] 1928) and more recently by Grinker in his textbook of neurology, page 587. Headache, vertigo, convulsions and retinal hemorrhages are common features. Increase in cerebrospinal fluid pressure is common. Grinker says that the relation between arteriosclerosis and hypertension as to cause and effect is not definitely known, but probably the sclerotic changes are secondary to the hypertension. Whether the hypertension is the result of a central process cannot be stated. The attack in December 1933 was one of the "cerebral vascular crises" common in this condition. As Grinker says, their mechanism is unknown. He suggests that "a small arteriole may go into spasm and relax quickly, but still the time may be long enough to produce quite a reaction in the parenchyma, an edema of the interstitial tissue and hyperemia of the neighboring vessels. The processes clearing quickly, leave a normal functioning area." Horace Evans (*Lancet* 2:583 [Sept. 9] 1933), in discussing hypertensive encephalopathy, also emphasizes ischemia and edema as bringing on the cerebral crises. The serious prognosis was justified, but fortunately, in this particular case perhaps the physician unknown to himself brought about a mental tranquility favoring subsidence of the cerebral process underlying hypertension.

POLYCYTHEMIA

To the Editor—A man aged 23 whose previous health was normal has been suffering for about six weeks with polycythemia. The hemoglobin is 122 per cent, red blood cells 6,200,000, eosinophils 4 per cent. There are albumin and casts in the urine. No signs of lead have been found. The patient was exposed to ethyl gas (lead) in washing airplane motors from June 1924 to April 1935. Can I consider tetra-ethyl lead as a causative factor? What clinically can I consider as the remote effects of tetra-ethyl lead in ethyl gas on a susceptible individual?

M D Ohio

ANSWER.—While the use for cleaning purposes of ethyl gasoline is not condoned, it is unlikely that a polycythemia can be attributed to tetra-ethyl lead in this cleaning agent. Two other possible causes should be considered as more nearly practical. The first of these is carbon monoxide. The query does not state that the airplane motors were in operation at the time of washing, but it is believable that any such work might at least at times be carried out under conditions providing exposure to this gas. It is reasonably well established that workers in garages and other places where moderate exposure to carbon monoxide is provided develop a mild polycythemia.

A second possible causative agent is to be found in the gasoline itself. Gasoline (benzine), kerosene, naphtha, Stoddard's solvent and similar substances are capable of inducing a stage of intoxication in which polycythemia is a feature. Ordinarily this condition comes early in the period of exposure. All in all, it is believed that greater significance should be attached to the influence of carbon monoxide if exposure can be shown to have existed.

The method of determining the 122 per cent hemoglobin may be of some importance. Current attitudes toward hemoglobin determination lead to unfavorable criticism of many widely used methods. Instead of expressing observations in percent, ages it seems that much more accurate results can be obtained through the determination of actual grams of hemoglobin in a given sample of blood. The Haden-Hausser apparatus is a usable instrument for the determination of hemoglobin on the gram basis. So far as is known, the remote clinical effects of tetra-ethyl lead are not dissimilar to those produced by other forms of lead, with the possible exception that tetra-ethyl lead may exercise a predilection for nervous system tissues. Tetra-ethyl lead differs from inorganic lead compounds with respect to toxic features in that it may enter the body by way of the skin. The extent that inorganic lead compounds enter the body through this portal is negligible. Notwithstanding the small amount of tetra-ethyl lead in a gallon of gasoline, this agent should not be utilized for cleaning purposes or for any other purposes that lead to extensive skin contact.

ROSE FEVER

To the Editor—A woman about 50 years of age complains of headaches dating from twenty years ago at about which time she had a criminal abortion with an infection. Five years later she had an appendectomy and oophorectomy on the right side. She had her tonsils removed five years later for she complained of rose fever. Now she comes to me with a history of having rose fever every June for twenty years. This year she got her attack in the middle of August. This so-called rose fever followed immediately on her smelling roses. The symptoms are typical of hay fever with itching of the eyes, lacrimation, coryza, a tickling sensation of the throat and difficult breathing at times. Roentgenograms of the sinuses are negative. Physical examination is negative. Pollen tests with ragweed, the grasses, timothy, red top, cottonwood and the common pollens are negative. The patient gives a negative history for food or animal sensitivity. Kindly advise as to probable cause and treatment.

M D New York.

ANSWER.—"Rose fever" is a title still used although scientifically incorrect. The symptoms coming on in May, June and July, consisting of rhinitis and conjunctivitis frequently complicated by bronchial asthma, have been definitely proved to be due to the inhalation of the pollens of various grasses, especially of June grass, timothy, orchard grass and redtop in the northern part of the United States. In the South, Bermuda and Johnson grass are most important.

The pollen of roses does not cause hay fever, except by close contact, as by inhaling roses or by working in a rose garden or in a florist shop. These statements are known to be facts because: 1. The pollen of grasses is carried by the wind and deposited on slides, the grass pollen is easily recognized under the microscope, the pollen of roses is not found on these slides unless the slides are placed very close to roses. 2. The symptoms of the patients coincide exactly with the time and quantity of grass pollination; they do not vary with rose pollination. 3. Skin tests are usually positive to grass pollen, sometimes to rose pollen also. 4. Inhalation of grass pollen in susceptible individuals is positive any time of the year; this may be true also of rose pollen.

Similarly, goldenrod is still often accused of causing the August-September hay fever, which as known for many years is due solely to inhalation of ragweed pollen.

In this patient the diagnosis is doubtful but should be cleared up by retesting as follows. The important pollens in her vicinity (to be found in any of several books on allergy or which may be ascertained on request from any of the several pharmaceutical houses manufacturing pollen extracts) should first be skin tested by the cutaneous method. If negative, the intracutaneous method should be tried with 1:1,000 dilutions of the pollen. If this likewise is negative, a few grains of the raw pollen should be laid against one of the lower eyelids and allowed to remain for five to ten minutes (conjunctival test); a positive reaction is shown by redness, lacrimation, photophobia and itching and, if severe, may be cleared up promptly by a drop or two of 1:1,000 epinephrine instilled into the conjunctival sac. If a positive reaction is obtained, the diagnosis of true hay fever is assured in this case because of the symptoms present. Treatment should be begun about March 1 of next year for grass hay fever if this should be found, and

about June 1 for ragweed hay fever if this is present. If both occur, the grass pollen extract should be injected in one arm, the ragweed in the other.

If the pollen tests are entirely negative the patient should be completely tested, cutaneously and intracutaneously, for non-pollen proteins, especially orris root, foods and animal derivatives. It is possible to have seasonal symptoms from one or more of these and the treatment will depend on the results of testing. Elimination of the causative factor is most important, if possible, if not possible, desensitization should be tried.

INFECTION OF UROGENITAL TRACT

To the Editor—I would appreciate advice as to further procedure with a case of gonorrheal prostatitis and evident gonorrheal arthritis. A white man aged 26 first infected in 1919 has had fifteen years of irregular treatment both by himself and by physicians. He came under my care in October 1934, complaining of an intermittent discharge burning on urination and pains in the sacroiliac areas. Examination revealed from 12 to 15 pus cells to a high power field but the urine otherwise was normal. The prostate was boggy and tender. Prostatic secretion was moderate in amount, containing white flakes and hundreds of pus cells seen under the microscope. Wassermann reaction was negative. Gonococcus fixation was positive. A 26 F sound passed with ease. Treatment has included prostatic massage every five to seven days, sexual hygiene, rest, methenamine diathery to the prostate every five days for two months, foreign protein therapy in moderate amount and Parke Davis gonococcus filtrate every seven days for the last eleven weeks. Local irrigation was done with 15,000 potassium permanganate twice daily during the periods of discharge and once daily or not at all when the discharge was absent. At present he complains of continued pain in the sacroiliac region especially after exercise or work and continued burning at the base of the penis. Very little discharge remains and that is after the use of the filtrate. Examination now reveals a nontender small prostate. There is very little secretion which contains occasional flakes or none and many pus cells under the microscope often in small clumps. The Kahn reaction is negative. Gonococcus fixation is positive. The second glass of urine shows an occasional white blood cell. Is a negative gonococcus fixation test to be hoped for in this case? I wondered whether malarial or other fever therapy would be of benefit and if so whether it could be obtained for the patient at one of the state hospitals. Any suggestion as to further procedure will be welcome kindly omit name. M D Illinois

ANSWER.—A chronic urethral discharge in a given patient is not indicative of gonorrhea.

The complement fixation test, if done properly, is a valuable diagnostic aid. In this instance one would doubt the accuracy of the test.

Gonococcus filtrate should not be used unless there is more positive evidence of gonococcal infection than is obtained in this case.

Examination of the upper urinary tract should be done by retrograde or intravenous urography with urine cultures. Careful examination should be made for focal infection (teeth and tonsils).

Heat therapy induced by malaria should not be considered or, if induced electrically, is of doubtful value.

There has been too much medication and instrumentation used here.

This patient seems to be suffering from infection of the upper urinary tract due to focal infection. Prostatic, urethral and joint involvement is a secondary manifestation of a systemic infection of some kind. In case of negative cultures, one should look carefully for tuberculosis of the urogenital tract.

FOOD POISONING DURING PREGNANCY

To the Editor—March 12 a husband and wife were stricken with vomiting and diarrhea apparently due to food poisoning. The woman is seven months pregnant. The husband was rather prostrated for three days but fully recovered. The woman who was well previously continued to have mild attacks of nausea and vomiting and felt ill until the 23d when she had occasional lower abdominal pains which continued until the 27th when obvious labor pains began combined with a sort of tetany of the uterus. The fetal heart became irregular and ceased about four hours after the onset of regular labor. Could this premature labor and fetal death have resulted from food poisoning? No analysis of the suspected food—in this case strawberry pie—was made. Please omit name. M D, New York

ANSWER.—The apparent food poisoning may have had nothing to do with the fetal death and premature labor in this case. Food poisoning accompanied by vomiting and diarrhea are not uncommon during pregnancy, but rarely is there interruption of gestation as the result of it. When food poisoning does lead to fetal death and premature emptying of the uterus, the cause is not definite. It may be due to a combination of factors such as toxins in the maternal blood, sudden and violent increases in intra abdominal pressure due to persistent and repeated vomiting and changes in metabolism. An interesting

fact is that pregnancy has been interrupted spontaneously in about one third to one half of all reported cases of mechanical intestinal obstruction.

OPACITY IN VITREOUS

To the Editor—A man, aged 59, is suffering from hyalitis. The patient's history goes back about two months at which time he had an attack of grip. He was laid up about five days with this illness. His chief complaint is the seeing of one spot floating before his left eye. The only freedom he has from this complaint is when he goes to sleep at night. He describes the spot as that of a half bird which continually floats before his left eye. He has had cataracts removed from both eyes, the right four years ago and the left one year ago. Other complaints are a slight weakness, frequent headaches and slight dizziness at times. He suffers from chronic constipation having always taken something for a bowel movement. On ophthalmoscopic examination slightly tortuous vessels in the optic disk are seen. No opacities can be determined. The heart sounds are of good force and rhythm. There is a slight systolic murmur at the apex. The pulse is of good volume and tension. The pulse rate is 80 beats a minute and the blood pressure is 140 systolic, 90 diastolic. The abdomen is slightly obese with the upper portion a trifle larger than the lower portion suggestive of an enlarged transverse colon. The Wassermann reaction is negative. The hemoglobin is 80 per cent. Red blood cells number 4,430,000, white blood cells 9,300, polymorphonuclears, 70 per cent, large lymphocytes 14 per cent, small lymphocytes 13 per cent, myelocytes 2 per cent, basophils, 1 per cent. Urinalysis on both a single sample and a twenty-four hour specimen is negative. Chemical examination of the blood reveals sugar, 129.0 mg, urea nitrogen 15.0 mg, urea, 32.1 mg. I have been treating the patient with saturated solution of potassium iodide and injections of solution of pituitary. The latter afford marked relief from headache. Any information as to the probable cause of the condition and an outline of treatment will be appreciated. Kindly omit name. M D New York

ANSWER.—The patient undoubtedly has a formed opacity in the vitreous and, as is so frequently the case in such conditions, has focused his attention on the opacity until it has become an obsession. Such opacities are not infrequently found after cataract extraction, particularly when there is the sclerosis of the retinal vessels, as evidenced by "slightly tortuous vessels in the optic disk." There is no known treatment today that will eliminate isolated vitreous floaters, but they will decrease in size with time and no longer command the all-arresting attention of the possessor.

SEPARATION OF RECTUS ABDOMINIS

To the Editor—A boy aged 3 years a normal child with negative family history complains of a peculiar pain in the umbilicus with some loss of appetite. During these attacks he lies on the abdomen for relief. The most recent attack came on simultaneously with a slight cough. The boy is vigorous and healthy and is of normal weight and height. Physical examination reveals considerable separation of the abdominal rectus muscle at the midline from the sternum to the umbilicus. There is no deep tenderness. There seems to be very little support to the abdominal wall in this separation. I have never heard or seen such a condition and would like to know whether or not there is such a malformation and if this could produce the symptoms complained of. Kindly omit name. M D Wisconsin

ANSWER.—The separation of the rectus abdominis in the midline between the xiphoid process and the umbilicus is not unusual in young children. This separation may be easily detected if the examiner's fingers are placed in the midline of the abdomen with the child lying on his back, and the child is then slowly raised to a sitting position. It has been said that so-called navel colic may be caused by a pinching of the peritoneum when separation of the rectus abdominis is present. Frequently small preperitoneal fatty masses that have penetrated through the linea alba because of a diastasis of the rectus muscles may be felt. It has been believed that these nodules, by drawing on the attached peritoneum, may produce critical attacks of pain, especially after eating. So-called navel colic is often of psychic origin and without organic basis.

SENSITIVITY TO SUNLIGHT

To the Editor—A white woman, aged 35, well nourished, a brunette has urticaria when any part of her body is exposed to the sun longer than five minutes. This may come on in an hour or so or it may be twenty-four hours. It is relieved by a soothing lotion and disappears in from twenty-four to thirty-six hours. Although she lives in southern California she had it while visiting in Oregon this summer.

G HORACE COSHOW M D Carpinteria Calif

ANSWER.—The best treatment for a case of this sort is avoidance of sunlight and the wearing of colored clothing. The patient can be desensitized by carefully graduated increasing doses of sunlight or ultraviolet rays applied to the skin generally. The doses should be so regulated as to avoid causing reaction. The patient should be warned against exposing the eyes to sunlight, since the retina might be damaged thereby.

The subject was discussed by W W Duke in an article entitled "Urticaria Caused Specifically by the Action of Physical Agents (Light, Cold, Freezing, Burns, Mechanical Irritation, and Physical and Mental Exertion)" in THE JOURNAL, July 5, 1924, page 3

DANGER OF TUBERCULOSIS FROM CONTAMINATED WATER

To the Editor—I am writing you for definite information regarding the effect of the chlorination of water on tubercle bacilli. In a nearby community the effluent from an Imhoff tank at a tuberculosis sanatorium discharges into a small branch a few hundred yards below. This branch in turn passes into a creek which serves as one of the sources of water for a certain outdoor swimming pond. Below this pond is another pond on which are located two other bathing resorts. The first pond is about two miles below the outlet of the tank the second pond about four miles below. The first branches and creeks in the neighborhood of the sanatorium apparently all reach these ponds. For this reason it is not practicable to divert the effluent to another creek. In view of this it has been suggested that a dry feed chlorination apparatus be set up over a manhole below the tank and thus chlorinate the effluent before it reaches its first destination. To what extent would you consider the health of bathers in these two ponds to be jeopardized as a result of the present set up? Would you consider chlorination of the effluent to be of any value in its effect on the tubercle bacilli? What solution or suggestions can you offer in regard to correction? Please omit name and address

M D South Carolina

ANSWER.—Although there seems to be no direct evidence that tuberculosis is contracted by bathing in contaminated water, the possibility cannot be altogether ignored. As is well known, the wide dissemination of tubercle bacilli makes the exact source of a tuberculous infection peculiarly difficult to trace. The situation described must be regarded as undesirable. On the other hand, considerable destruction of tubercle bacilli may take place in the Imhoff tank, other germicidal influences are at work in the flowing stream, and there would seem to be high dilution. The danger to bathers from tuberculosis would seem to be slight. Chlorination of the effluent from the Imhoff tank is advisable, not only to meet possible criticism but to insure that the effluent is free from intestinal pathogens, which may constitute a more serious menace than tubercle bacilli. It might be wise, under the conditions described, to use special care within the sanatorium in the cremation of sputum cups

CHRONIC CONJUNCTIVITIS

To the Editor—A woman aged 23 complained of pain in the left eye with photophobia and a feeling as of sticks in the eye. The attack was ushered in by and recognized by the seeing of halos around lights at night. She began to have these attacks in 1932 when they were treated as iritis. They have recurred coming more frequently so that she has had two during the past week. She is highly sensitive to many things and has been on a diet the past year with little apparent effect, since she has had more attacks during the past three months than she had before. The physician who had seen her last was treating her for allergic glaucoma and advocated intravenous sterile peptone 1 cc for the attacks. I gave her the peptone and she seemed to get relief. I have never heard of allergic glaucoma before. There is no marked difference in tension that I can determine and the disk seems normal immediately after the attack wears away. Can you help me make a diagnosis or explain the action of the peptone? Please omit name

M D Massachusetts

ANSWER.—"Allergic glaucoma" falls into much the same category as the Purple Cow. The described condition sounds very much like a chronic conjunctivitis with subacute exacerbations. The secretion that could result from this might account for the halos. Neither glaucoma nor iritis would occur in attacks twice a week with spontaneous disappearance. The peptone acts merely as a foreign protein, which naturally would be beneficial to the inflammatory process, whatever it was

IMPETIGO OR PEMPHIGUS?

To the Editor—Please advise treatment for a woman who following erysipelas of the face and scalp developed patches up to an inch in diameter of dermatitis which is thick, brownish greasy and resembles seborrheic dermatitis to me. These patches are scattered over the entire face and scalp and when removed leave raw areas. Ointment of rose water hydrous wool fat sulphur ointment and ointment of ammoniated mercury have given no relief. Please omit name and address

M D Texas

ANSWER.—From so meager a description it is difficult to formulate theories about a possible diagnosis. If impetigo, there should be the initial vesicle visible at times, at least, and some benefit should have been derived from the use of ointment of ammoniated mercury. Nothing is said of temporarily bald areas in the scalp on healing of the excoriations, such as impetigo sometimes leaves

If impetigo seems to be the probable diagnosis, and the rule of prevalence favors it, an adhesive plaster dressing over each lesion will prevent spread and eventually result in cure. Some antiseptic lotion, such as 1:5,000 mercuric iodide solution, should be applied between the dressings once a day. The probable diagnosis is impetigo, spread by the fingers. This is sometimes not benefited by ointment of ammoniated mercury.

Nothing is said of symmetry of the lesions on the face. The Senear-Usher type of pemphigus produces thick greasy crusts, but there should be involvement of the cheeks resembling lupus erythematosus, and there should be bullae on the body or in the mouth

DIAGNOSIS OF SYPHILIS

To the Editor—A white woman came into my office complaining of sore mouth which looked very much like a Vincent's infection superimposed on pyorrhea. No smear was made from the mouth because of recent antiseptics. There was no other evidence of syphilis but blood was taken for examination. This blood showed the Wassermann test slight fixation 1 plus and with the Kahn precipitation test 2 plus. The patient was given neosarsphenamine, 0.3 Gm and asked to return in one week. At this time blood was taken from her and from her husband and both gave negative reactions. No other treatment was given than treatment by her dentist. I took blood for examination again today. Should this blood come back positive I feel that I should continue treatment should it come back negative however, should I consider that this is sufficient evidence to discontinue all treatment except local treatment for pyorrhea provided follow up blood examinations are made?

M D Virginia

ANSWER.—The diagnosis of syphilis in this case was based on insufficient evidence. There are many oral lesions that simulate syphilis. The diagnosis of a Vincent's infection can be easily corroborated by a smear. Unless further positive serologic or clinical evidence is obtained, additional antisyphilitic therapy is not justified

TREATMENT OF VITILIGO

To the Editor—Please give me information concerning responsive treatment for abnormal pigmentation of the skin. I have a patient who has the characteristic milk white patches on the hands and arms. Apparently it is a disturbance of the normal pigmentation of the skin and I believe not an uncommon condition. It seems that he has been told that there is a treatment being used now that helps greatly to remove the ugly blemishes. If you cannot go into the details of the treatment, if any I would be glad of any references

CHARLES G PRATHER M D Westwood N J

ANSWER.—The use of gold sodium thiosulphate intravenously in the treatment of vitiligo was advocated by H C L Lindsay (The Treatment of Leukoderma with Gold Sodium Thiosulphate, *Arch Dermat & Syph* 20:22 [July] 1929). He was successful in three cases. In other hands it has not been so successful. The patient's health should be built up in every way possible. In winter, ultraviolet treatments should be given, in summer, sun exposure carefully graduated. After many such exposures the pigment will begin to return in most cases and continued treatment will bring about great improvement. The treatment is tedious but not disagreeable and is probably of general as well as local benefit. Active pulmonary tuberculosis may be a contraindication, as are pellagra and a very blond freckling skin

SWIMMING AFTER EATING—RAW APPLE DIET IN DYSENTERY

To the Editor—1. There is a widespread belief among the laity that taking a bath or going for a dip in the lake after a meal is harmful. Obviously the strenuous exercise involved in swimming is not desirable immediately after a meal but I wonder if there is any real evidence that mere wading into the water or bathing is undesirable. 2. What are the various methods of preparing the raw apple diet for children with diarrhea?

M D New York

ANSWER.—1. Mere wading in water or taking a bath after a meal is not likely to be harmful to a person with a good digestive and circulatory system. When, however, either digestion or circulation is enfeebled, the changes in the distribution of blood produced by a cold plunge may interfere with the function of the enfeebled organ.

2. Moro (1929, 1931), who established the raw apple diet as a means of treating diarrhea, used thoroughly ripe, peeled and cored apples and converted them into a reddish brown pulp by rubbing them on a grater. From one to four tablespoonfuls or more of this pulp was given every hour or two, the average quantity administered in the twenty-four hours being thirty tablespoonfuls. For forty-eight hours no other food or medicine was given, excepting that a little water or weak tea was allowed if the patient was thirsty. If the patient was dehydrated, physiologic solution of sodium chloride with or without

dextrose was administered. Banana pulp may be added to the apple, if the latter is refused. It makes the apple pulp more palatable. After the third day a transitional diet is used by adding toast, cereal and potato gruel, scraped meat and cocoa.

MENINGITIS IN INFANT AFTER PNEUMONIA

To the Editor—A baby, aged 1 month, contracted pneumonia during an epidemic. It made a good recovery from the pneumonia but about forty-eight hours before it died spasms began, and according to the nurse fifty-one occurred. Just before death the head rapidly dilated until it was approximately twice its normal size. I cannot account for the dilatation of the head. Omit name, please. MD Kansas

ANSWER—Meningitis probably developed after the pneumonia. It is impossible to know the extent of the meningeal inflammation though it is most likely that the inflammatory process occurred, in part at least, at the base of the brain, interfering with the passage of the cerebrospinal fluid to its absorptive surfaces. In consequence of the obstruction to the flow of fluid produced by the acute meningitis, a hydrocephalus occurred, which would explain the rapid dilatation of the head.

The frequent convulsions were undoubtedly due to the irritation caused by the meningeal and brain inflammation, both of which occur during the course of meningitis.

AIR AND BONE CONDUCTION IN HEARING

To the Editor—When testing hearing with a 2 A audiometer with a rubber diaphragm over the ear piece is this testing bone or air conduction? NORTON H. GOOD MD, Buffalo

ANSWER—In testing the hearing with the audiometer with the earpiece placed in contact with the auricle, the perception one gets is partly the result of air conduction and partly the result of bone conduction. With the rubber diaphragm placed over the earpiece the element of air conduction will be less than in using the earpiece without a rubber diaphragm but the perception is still due partly to air conduction and partly to bone conduction.

ANTITYPHOID VACCINATION

To the Editor—I have been accustomed to using typhoid vaccine in the usual three dose series of injections repeating the whole series of three injections when a period of time had elapsed or conditions arose that seemed to indicate revaccination. I have heard of the practice of a physician in this community of giving one injection of typhoid vaccine every spring to children previously given the usual three injections. Is this practice any better than repeating all three injections after a lapse of two or three years? Is this practice widely followed? I have under my care a large group of children whom I have immunized against typhoid with the usual three injections. None is going to rural or typhoid communities. How should immunity in these children be maintained? MD Georgia

ANSWER—So far as known, the practice of giving one injection of typhoid vaccine every spring is not followed widely at all. The protective effect of such injections has not been studied carefully and it is not known whether the practice is better than repeating the usual three injections when indicated.

In children who have received the usual three injections, no other way is known of maintaining and reinforcing the immunity than revaccination after a number of years or when conditions arise that definitely require effective protection against typhoid.

AUTOHEMOTHERAPY IN URTICARIA

To the Editor—Recently a patient of mine who is suffering from urticaria of unknown or rather undiscoverable origin was advised to have 10 cc of blood drawn from the median basilic vein and injected into the gluteal muscle this procedure to be repeated once or twice weekly for from six to ten weeks. Will you please inform me as to the rationality of this procedure? Is it a method of foreign protein shock? Is it preferable to sterile milk or some other form of foreign protein? Kindly omit name. MD West Virginia

ANSWER—The use of autohemotherapy in urticaria is an established procedure among others, and the results obtained are often striking. In cases of nervous origin, however this procedure may also fail. It is believed by some workers that autohemotherapy is antianaphylactic, and other studies have indicated that the procedure lessens the permeability of the blood vessels. Rejection of the patient's own serum or blood is believed by some writers to bring about a desensibilization. The treatment should be continued for several weeks after the cessation of all symptoms. It is a method of nonspecific therapy that is a very mild form of foreign protein shock and exerts an action in some conditions, such as urticaria, that is preferable to sterile milk or some other form of foreign protein.

CATARACTS AFTER DINITROPHENOL

To the Editor—Kindly outline to me the course and prognosis of cataracts developing in younger women as a result of treatment with dinitrophenol. Can these cataracts be treated and operated on the same as senile cataracts with the same expectation as to the results? The patient is 39 years old and the cataracts in each eye have developed and matured in less than thirty days. They have the same appearance as ordinary senile cataracts except that the lens is evidently greatly swollen, because while there is no dangerous tension at the same time the anterior chamber is practically obliterated and the pupils remain dilated.

MD Missouri

ANSWER—Ophthalmologists are just beginning to learn about the course of cataracts as a result of dinitrophenol. In the early stages there are opacities under the anterior and posterior capsules. Later the whole lens becomes opaque and swollen. Results in those which have been operated on have been just as good as those operated on for senile cataract. In some cases the opacities were not noticed until after treatment had been stopped but went on to complete maturity afterward.

HEMOLYTIC JAUNDICE

To the Editor—Is it possible to have hemolytic jaundice without any enlargement of the spleen or any visible jaundice even during exacerbations? A man who has been anemic for eighteen years has increased fragility of the red cells and an increased icteric index. He has exacerbations during which his red cells drop to a million. The color index is high. No parasites have been found in twenty examinations including examination for filariasis. The leukocyte count is normal with a tendency toward eosinophilia and the platelet count is normal. Does such an atypical picture ever occur in hemolytic jaundice? Please omit name.

MD Missouri

ANSWER—Hemolytic anemia may occur rarely without splenomegaly and with a slight increase in serum bilirubin. The long history of anemia with crises, which result from the destruction of blood and which are accompanied by severe anemia and increased serum bilirubin, are typical of this disease. There may or may not be a familial history of icterus. The reticulated erythrocytes are increased, as a rule, particularly during the crises, and the fragility of the erythrocytes to hypo isotonic salt solution is increased. Morphologically the erythrocytes usually are smaller than normal, although many macrocytes (regenerative) are present. Most of the microcytes are well filled with hemoglobin and appear to be spherical. Slight enlargement of the spleen may occasionally be demonstrated by an oblique roentgenogram.

If this case meets the preceding criteria, with the exception of demonstrable splenomegaly, the diagnosis of hemolytic anemia is warranted.

WATERMELON AND WHISKY

To the Editor—Time and again one hears that it is often fatal to eat watermelon and then take a drink of gin or whisky. Is there any truth in this? Kindly omit name.

MD Florida

ANSWER—There seems to have been no such accident reported in the literature, and there apparently is no good reason why it should happen.

SIMULTANEOUS IMMUNIZATION AGAINST INFECTIOUS DISEASES

To the Editor—In *Queries and Minor Notes* in *THE JOURNAL* July 20 page 221 in your discussion on the simultaneous inoculations against smallpox and diphtheria you say that if no emergency exists it probably would be best at this time not to immunize against diphtheria and smallpox simultaneously. I wish to bring to your attention the procedure that I have been using in immunization against smallpox and diphtheria. All children presented for immunization are simultaneously immunized against smallpox and diphtheria. The materials used are glycerinated smallpox virus vaccine and alum precipitated toxoid. I have inoculated approximately 1000 children by this method varying in age from 4 months to 13 years. Multiple immunizations of this character have been found as effective as separate immunizations and are much accompanied by any greater reactions than those produced by separate inoculations of the respective materials. By this method of immunization it is possible to protect a greater number of children at one sitting against these two diseases.

In a series of 100 cases in which I have studied the simultaneous multiple immunization against smallpox and diphtheria I found that the reactions were no greater than in the single immunizing treatment and that the immunity and the rapidity of immunity were not affected.

I have come to the definite conclusion that the simultaneous multiple immunization against smallpox and diphtheria is a practical method applicable as a routine procedure in mass immunization as well as in private practice that the simultaneous immunization against smallpox and diphtheria is a safe and effective procedure.

Book Notices

The Appraisal of Public Health Activities in Pittsburgh Pennsylvania 1930 and 1933 By Marian H. Ewalt Research Assistant Bureau of Social Research Federation of Social Agencies and Ira V. Illscock Professor of Public Health Yale School of Medicine Paper Price \$1.00 Pp 125 Pittsburgh Bureau of Social Research Federation of Social Agencies of Pittsburgh and Allegheny County [n.d.]

Standardization of the essentials of public health practice on a quantitative basis has been a ten-year aim of the Committee on Administrative Practice of the American Public Health Association, though the pioneer work in such standardization was done by Chapin in 1915 for the Council on Health and Public Instruction of the American Medical Association, and reported in *THE JOURNAL*. The Chapin report in book form, has become a rare and valued piece of public health literature. The work under review is an excellent example of the health appraisal at its best. As its makers have realized from the beginning, the appraisal idea has possibilities of evil as well as of good. It is only a quantitative measure, though some quantitative measures may in themselves be indications of quality, if little or nothing is being done toward a desirable objective, obviously the quality of progress is poor. On the other hand much activity does not in itself indicate quality. The difficulties encountered in the effort to establish objective measures of quality in public health endeavor have not yet been overcome. All this by way of background for consideration of the report on public health activities in Pittsburgh. This is a measure of the organization of public health agencies in that city, and the quantity of work performed by them, according to the 1934 revision of the Appraisal Form for City Health Work published by the Committee on Administrative Practice. Health activities in Pittsburgh official and voluntary are clearly described in sufficient detail to give a comprehensive picture of what the community is doing. Pittsburgh's score on a basis of a maximum 1,000 points is 790, a creditable showing but one leaving room for growth and development. The significant fact in the report is that it represents the work of a community committee in which the active agencies interested in public health work and social service work in Pittsburgh have cooperated. The Medical Society of Allegheny County endorsed the survey and took an active part in it. There was no minority report.

In this appraisal Pittsburgh can find a chart for planning and directing its health progress for the next five years with a clear understanding on the part of all concerned as to what has gone before and therefore a minimum liability of misunderstanding or conflict in planning for the future. In this report public health officials, social workers and the medical profession may find an example of community cooperation for better health. More of this kind of cooperation more such reports will not only enrich the literature of public health but contribute to progress toward the common objective, the better health of the people.

Recherches expérimentales sur quelques esters de la choline Par Maurice Villaret, professeur à la Faculté de médecine de Paris. L. Justin Besançon médecin des hôpitaux de Paris et René Cachere chef de clinique à la Faculté de médecine de Paris. Paper Price 38 francs Pp. 254 with 79 illustrations Paris Masson & Co 1934

This monograph is essentially a record of the pharmacologic studies conducted by the authors on various esters of choline derivatives. After a brief outline of the chemistry of the choline and their general pharmacology, the authors present their own studies in two main parts. In the first part they describe in detail the action of the chlorides or bromides of various esters such as acetyl, formyl isobutyryl and methylacetyl and the carbaminoyl esters of choline. Most of the experiments were conducted on dogs the drug being given by intravenous, subcutaneous or intrajejunal injections. The cardiovascular system and the site of the action of the choline esters thereon were first studied and next in similar manner the action on the cerebrum and on respiration. From these the authors conclude that death is produced in choline poisoning through its action on the respiration. Ergotamine tartrate was found to intensify the respiratory response. The actions of acetylcholine and methylacetylcholine on smooth muscle were determined by studies on the intestinal gallbladder, bronchial and iris muscu-

latures. Acetylcholine was found to stimulate salivary and pancreatic secretion by "direct action." Acetylcholine does not alter the effects on blood pressure observed on stimulating the peripheral or central ends of the pneumogastric nerve. From one experiment on a dog, the authors conclude that the intravenous administration of methylacetylcholine produces a fall in alkali reserve, dextrose and water, but a rise in protein content in the blood. The question of the hormone nature of acetylcholine is reviewed briefly. The second part covers the studies on the effects of choline derivatives on man. The importance of the purity of the product and of the solvent used as a vehicle is stressed. Such solvents as diacetyl glycerol, monoacetyl glycol ethyl lactate and diethylene glycol are recommended mainly because they prevent the hydrolysis of the acetylcholine ester. The intravenous injection is not recommended. The effects of the intramuscular or subcutaneous injection of methylacetylcholine and acetylcholine esters on vasodilatation in the retina on peripheral dilatation and on gastric and pancreatic secretions are reported. The authors suggest acetylcholine as a good substitute for histamine in testing achlorhydria. The work is well illustrated by excellent reproductions of kymograph records. It is a good general treatment of a broad survey of the subject.

The Rise of Modern Physics By Henry Crew Second edition Cloth Price \$4.00 Pp 434 with 16 illustrations Baltimore Williams & Wilkins Company 1933

The increasing use of physical therapy has caused the medical profession to appreciate the value of a knowledge of physics. This volume on the history of physics is intended for readers who have had little previous knowledge of the subject but who would be glad to have an informal introduction to the fascinating science of physics. The chapters on the foundation of modern optics pioneers in electricity and magnetism, the nature of heat, the discrete nature of matter, electromagnetism, the origin of modern electrical units, the inertia of electricity and the rise of modern spectroscopy indicate the interest this volume should have for the medical profession. For instance the standard unit of measuring the wavelength of radiant energy is the angstrom unit. How this originated as the wavelength of the red cadmium line independent of the metric system enables one to comprehend its significance more than a mere definition does. Archimedes, who was born about 287 B. C., discovered the most fundamental principle of hydrostatics, which is used in underwater exercises.

While the science of physics has aided medicine, many physicians have made worthy contributions to physics. Empedocles (490-430 B. C.), a statesman physicist and physician, wrote his views in poetry, explaining the cosmos in terms of the elements earth, air, fire and water. Crew says that few ideas in physical science have played a more conspicuous part, and perhaps none for a longer time, than the four elements of Empedocles.

Jerome Cardan (1501-1576), a physician and mathematician, wrote a book that represents the best physical learning of his time. In the early part of the nineteenth century Sir Humphry Davy who was a practicing physician in Cornwall until Beddoes made him an assistant, received scientific honors for his work in physics from many European countries.

Dr W. H. Wollaston (1766-1828), a London physician and chemist, well known for his discovery of the elements palladium and rhodium, observed for the first time in 1802 that the spectrum of sunlight is crossed by dark lines. He also succeeded in decomposing water by the sparks of a frictional electric machine.

The author remarks that no serious minded student of physics will fail to make the acquaintance of Dr Thomas Young, for he is the last man of the race who knew everything that was to be known. His explanation of color vision as modified by Helmholtz is today perhaps the most widely accepted if not the best, of the various theories on this subject. His contributions to science cover many fields of physics.

In 1855 Dr David Alter a practicing physician of Pennsylvania, used the electric spark to map the spectrums of eleven different elements and metals.

To those interested in physical therapy it is of interest to find that the author gives W. W. Coblentz a member of the

Council on Physical Therapy, the credit of developing with Melloni and Pfund the use of the thermo-electric current in the measurement of temperature and in the detection of minute quantities of radiation. The delicacy of these modern thermocouples is so great that the radiation from a single candle at a distance of fifty miles can be detected. Crew's book should prove interesting and profitable reading for all physicians and especially to those interested in the use of physical therapy.

The Image and Appearance of the Human Body. Studies in the Constructive Energies of the Psyche. By Paul Schilder M.D. Ph.D. Research Professor of Psychiatry New York University. Psyche Monographs No. 4. Boards. Price 10/6. Pp. 353 with 7 illustrations. London: Regan Paul Trench Trubner & Co. Ltd. 1935.

For years the author of this monograph has been making observations in neurology and in psychiatry tending toward the development of the hypothesis which he now expresses. Before 1926 he had written a first thesis on the present central theme, namely, that every individual has in his mind a set of ideas or perceptions which present to him an unconscious scheme of his whole body. While the author admits that there have been partial hypotheses leading up to this idea, he also brings out that there lies a basic concept that reveals to the psychiatrist and the neurologist the reason why some of the more obscure symptoms of nervous and mental disorder take the form that they do. Since the writer is a prominent neurologist with much psychoanalytic training, he is able to present by means of extensive references to the technical literature as well as by means of numerous valid and interesting cases from his own experience the fact that, with certain neurologic diseases, wherein there is destruction of brain tissue, the patient's ideas of his body form and structure are lost. By means of psychoanalysis of functional cases in which changed bodily ideas are symptoms, some explanations for these changes can be deduced. As examples of the first type of case the author presents those paralyzed patients who ignore their paralysis and the phenomenon of phantom limbs after amputation, and of the second type the neurotic, particularly the hysterical, who use some other part of the bodies for the erogenous zones. There is also a social concept of the body with varying changes in ideas of nearness and contact with those who enter into the individual's sociopschoanalytic picture. The monograph is carefully worked out and well systematized, and the style is excellent. One can see that it is not intended as casual reading for physicians in general, even though the ideas are expressed in such a way that lay readers can get a great deal from it. But for the neurologist, the psychiatrist and the psychologist it represents a neat interweaving of neurology and psychiatry which may lead to significant progress in these fields or, if not that, add an intelligent academic standpoint, which has not previously been made readily available concerning certain types of lesions. There are two appendices, one presenting case histories, the second, illustrated with diagrams, showing the neural structures involved in the body image process.

Midwifery. By Ten Teachers under the direction of Clifford White M.D. B.S. F.R.C.P. Edited by Sir Comyns Berkeley J. S. Fairbairn and Clifford White. Fifth edition. Cloth \$0. Pp. 740 with 294 illustrations. Baltimore: William Wood & Company. 1935.

This edition presents evidence of a thorough revision and it includes discussions of practically all the new developments in obstetrics. As with the previous editions, the ten teachers share a common responsibility for the book and there is no way of telling which of the authors wrote any particular chapter. Four separate chapters are headed "The Toxemias of Pregnancy." One contains a general discussion of the subject of toxemias, the second is devoted to preeclampsia and eclampsia, the third takes up hyperemesis gravidarum and acute yellow atrophy of the liver, and the fourth deals with toxic antepartum hemorrhage. In addition to these four chapters devoted to the toxemias there is a separate chapter on albuminuria. The authors favor the conservative treatment of eclampsia. For most cases of placenta praevia the authors advocate the use of a Colpeurynter, Willett's forceps, a vaginal pack or version. They believe that abdominal cesarean section has a limited field in cases of placenta praevia. For the control of postpartum hemorrhage after delivery of the placenta, the authors recommend compression of the uterus between one

fist in the vagina and the other hand on the abdomen. They condemn intra-uterine packing, but many prominent obstetricians in this country have found uterine tamponade a valuable and sometimes life-saving procedure in cases of severe postpartum hemorrhage. In the discussion on analgesia, the authors say "The routine administration of powerful narcotic drugs in normal cases to obtain 'painless labor' cannot be defended on medical grounds." This question has recently aroused a great deal of controversy in Great Britain, and the authors express the sentiment of most obstetric authorities of that country. A special chapter is devoted to the use of solution of pituitary in labor. In the discussion on cesarean section, both the classic and the cervical operations are briefly described. However, the author who wrote this chapter presumably has not had personal experience with the cervical operation as it is generally performed. The book is well written and the illustrations are numerous and instructive. It should prove to be popular.

Praktische Anatomie. Ein Lehr- und Hilfsbuch der anatomischen Grundlagen ärztlichen Handelns. Von Dr. T. von Lanz a. o. Professor für Anatomie an der Universität München und Dr. W. Wachsmuth Privatdozent für Chirurgie an der Universität Bonn. Band I Teil 3. Arm. Cloth. Price 20 marks. Pp. 276 with 208 illustrations. Berlin: Julius Springer. 1935.

The word "praktische" in the title does not signify that the book is a manual of dissection. It indicates that the gross anatomy of the arm is presented in its functional and clinical significance. It deals with proportions, with movements, with the work and use of the arm and with the risks of injury and disease to which it is especially exposed. Muscle insertions are considered in relation to movements and to their effect on amputation stumps. Left-handedness and its relation to accidents are discussed. The sites and lines of fracture are indicated. The first part deals systematically with the skeletal, arterial, venous and lymphatic systems, concluding after forty-eight pages with the nervous system. The larger part (up to page 246) is regionally arranged, beginning with the shoulder and concluding with the finger tips. Although it is an "applied" anatomy, development, evolution and the biologic significance of structure are treated with more than ordinary appreciation. One of the authors is an anatomically minded clinician, the other a clinically minded anatomist.

The illustrations, for the most part new, are instructive and beautifully reproduced. A valuable feature is the well selected bibliography arranged under headings identical with those of the text.

Recent Advances in Endocrinology. By A. T. Cameron M.A. D.Sc. F.I.C. Professor of Biochemistry Faculty of Medicine University of Manitoba. Second edition. Cloth. Price \$5. Pp. 496 with 55 illustrations. Philadelphia: P. Blakiston's Son & Co. Inc. 1935.

The second edition of this pretentious work appears within a period of little over a year after publication of the first—a tribute to the efforts of author and publisher to keep it abreast of recent developments in endocrinology. The new volume is longer by about forty pages than its predecessor (which was reviewed in *THE JOURNAL*, May 5, 1934). Actually, however, the new material exceeds the content of the additional pages, as parts of the text of the first edition have been omitted from the second. The author has avoided some of the errors of the first edition (chiefly by deletion) but unfortunately he has added as many or more in the new material. For information on chemistry in many cases he now refers the reader to the book by Harrow and Sherwin, the deficiencies of which have already been pointed out in *THE JOURNAL* (Aug. 18, 1934).

As material in the present volume has been considered in detail in the previous review, it need not be discussed again. A few more points may be considered here, however. The author states that Allen and Doisy have demonstrated the presence of theelin (estrone) in ovarian follicular fluid. He claims further that "replacement therapy with spayed animals and injection experiments with immature animals have demonstrated conclusively that oestrone is the ovarian principle." Both statements are, of course, in direct contravention of the facts, isolation of theelin from ovarian follicular fluid has never been reported. "Thymophysin," a combination of extracts of thymus and pituitary, is given the benefit of serious discussion, although the Council on Pharmacy and Chemistry several years

ago exposed it as a useless and unscientific preparation. For some reason, the author includes a discussion of the drug ephedrine. If it was his intention to consider the effects of chemical modifications of the epinephrine molecule, it is surprising that descriptions of other related drugs such as synephrin, neosynephrin or beizedrine are not also presented. A section is devoted to the pupil body, yet none of the recent work (especially that by Burger, by Engel and by Saphir) is considered.

As with other recent reviews of endocrinology, this book may be recommended only to those with a sufficient knowledge of the subject to estimate the probable accuracy of the dissertations on the various subjects.

The American Illustrated Medical Dictionary. A Complete Dictionary of the Terms Used in Medicine, Surgery, Dentistry, Pharmacy, Chemistry, Nursing, Veterinary Science, Biology, Medical Biography, etc., with the Pronunciation, Derivation and Definition. By W. A. Newman Dorland, M.D., F.A.C.S., Lieut. Colonel M. R. C. U. S. Army. With the collaboration of E. C. L. Miller, M.D. Seventeenth edition. Fabrikoid. Price \$1. Thumb Index \$7.50. Pp. 1573 with 645 illustrations. Philadelphia & London: W. B. Saunders Company, 1935.

Since the year 1900, this medical dictionary has progressed through seventeen editions, that fact alone signifies the usefulness of the book as well as its popularity. Medical terminology is ever growing and, without constant revision such as has been done with the American Illustrated Medical Dictionary, it would scarcely be possible to keep in touch with all the new technical terms. The first edition of this dictionary contained only 770 pages while this edition contains 1573, an increase of more than 100 per cent. In addition to the ordinary dictionary material there is a large amount of information arranged in tabular form. There are tables of tests, tables of staining methods, tables of methods of treatment, a table of the arteries, a table of the veins, tables of weights and measures, and a table of the doses and actions of numerous drugs. There are numerous illustrations many of which are in color. The present edition retains the form of the previous edition in that the book is flexible, is thumb indexed, and is of convenient size.

Lethargic Encephalitis. By Isador Abrahamson, M.D., Associate Neurologist, Mount Sinai Hospital, New York City. With a foreword by William J. M. A. Maloney, M.D., LL.D., Consulting Neurologist, City Hospital, New York City. Cloth. Pp. 103. New York, 1935.

This book, sponsored by the Isador Abrahamson Fellowship as a memorial to the deceased author, consists of a foreword of seven pages by Dr. Maloney and six papers on encephalitis by Dr. Abrahamson published between the years 1920 and 1925. In the foreword Dr. Maloney credits Abrahamson with being the first to recognize epidemic (lethargic) encephalitis in America. In the first chapter, entitled "The Epidemic of Lethargic Encephalitis," Abrahamson states that he recognized this case in New York in September 1918. He states that the second case was detected by Major Pothier at Camp Lee in October 1918, the third a few days later at Des Moines by Dr. Ely, and the fourth in Chicago a few weeks later by Dr. Bassoe. The second chapter deals with the mental disturbances, the third with motor disturbances, the fourth with chronicity, the fifth with syndrome changes, and the sixth with changes in muscle tone. A complete list of Dr. Abrahamson's publications is added.

The Child: His Origin, Development and Care. By Florence Brown Sherbon, M.D., Professor of Child Care and Development, Department of Home Economics, University of Kansas. Paper. Price \$3.50. Pp. 107 with 147 illustrations. New York & London: McGraw-Hill Book Company, Inc., 1934.

The endeavor of the author is to present to the student facts about the child from his earliest origin until he enters school, so that later on the student will be able to study the literature on child development understandingly. There are chapters on biochemistry, heredity and biology, followed by material on reproduction, the glands of internal secretion, pregnancy and childbirth. The second portion of the book deals with the care of the child and the third portion with behavior, development and training. In the book are synthesized the current scientific discoveries in terms of child care and training. The material is presented in such a way that it should be easily understood by the student, and there is adequate bibliographic and

reference material. As a textbook for the teaching of child care development and training, the book should prove quite satisfactory.

Methods of Treatment. By Logan Clendening, M.D., Clinical Professor of Medicine, Medical Department of the University of Kansas. With chapters on special subjects by H. C. Andersson, M.D. and others. Fifth edition. Cloth. Price \$10. Pp. 870 with 102 illustrations. St. Louis: C. V. Mosby Company, 1935.

Like its predecessors, the present edition presents the subject of therapeutics in two parts: first, methods, second, applications. Chapters on the rationale of various types of therapy comprise the first 526 pages of the work, the remaining 333 pages (exclusive of the index) being devoted to the application of these procedures and techniques in a selected list of diseases, a plan which the author believes to be the most effective for avoiding unnecessary repetitions. At times these applications are presented in quite terse outline form, while in other instances the discussions are much longer, a notable example of the latter is the fine article on the psychoneuroses, which doubtless comprises one of the author's indulgences in "the luxury of some philosophic comment" of which he speaks in the preface. Among those works which aid the student in understanding the various therapeutic techniques and procedures in clinic and ward, this book is preeminent.

Nursing Mental Diseases. By Harriet Bolloy, R.N. Third edition. Cloth. Price \$2.50. Pp. 258. New York: Macmillan Company, 1935.

This is the first revision in several years of Miss Bailey's excellent work. In the present edition a brief summary of personality development and alteration has been added for the purpose of emphasizing the importance of understanding mental reactions so that the patient may be nursed more efficiently. Other changes are noted throughout the work. The text is limited to nursing and aspects of psychiatric diseases and disorders that come in the field of nursing practice. Many additions have been made to the nursing procedures with which this textbook is primarily concerned. It is generally acknowledged with regret that mental symptoms, so frequently found in some form and degree in almost any of the disorders of physical function, are almost totally neglected in the usual training course for nurses. While Miss Bailey's book is primarily written for the nurse specializing or intending to specialize in psychiatric nursing, it covers a subject not too technical to be included in the training course of every good school. The thoughtful and understanding nurse, through simple procedures, can often do much to relieve a patient who is depressed, to quiet a restless and excited one, to arouse one who is indifferent, and to manage one who is resistive and quarrelsome. No nurse can read this volume without a much better understanding of the nervous patient. For those specializing in psychiatric nursing it will be found an invaluable aid. The work is most highly recommended.

Sémiologie des affections de la bouche et des dents. Par le Dr. Charles Ruppe. Paper. Price 32 francs. Pp. 271 with 53 illustrations. Paris: Masson & Co., 1935.

This covers only the symptomatology of the diseases of the mouth and teeth, including the maxillary sinus, the floor of the mouth, the parotid region and the cervical glands. The illustrations are simple drawings for the most part of a schematic character depicting the relationship of symptoms to anatomic structure. Seventeen tables summarize the contrasting pictures of closely related conditions. This material is valuable for both the clinician and the student with respect to differential diagnosis and a clear understanding of the part played by structure in modifying symptoms.

Manual of Diabetes. By J. J. Conybeare, M.C., M.D., F.R.C.P., Physician to Guy's Hospital. Cloth. Price \$2. Pp. 123 with 5 illustrations. New York and London: Oxford University Press, 1935.

This manual is far above the average of its type and is heartily recommended. It is relatively short, contains essentials, and is well written and in such a manner as not to make the patient apprehensive. It is primarily for patients but will be found useful for physicians. The text is sound and any doctor would find his patient helped by its perusal. The English flavor of its language adds rather than detracts from it for American readers.

Medicolegal

Hospitals, Charitable Liability for Negligence of Nurse—The physician-defendant operated on the plaintiff at the defendant hospital. Subsequently it was discovered that a sponge had been left in the patient's body, and she and her husband sued the physician and the hospital. The trial court directed a verdict in favor of both defendants but later granted the plaintiffs a new trial. The defendants appealed to the district court of appeal, third district, California.

The alleged acts of negligence on which the plaintiffs relied to fasten liability on the hospital were that the sponges used in the operation did not have tapes attached to them and that the nurse assisting the physician, who had been furnished by the hospital, failed to count the sponges used. The hospital defended, claiming that it was a charitable institution and that it used due care in the selection of its nurses and hence was exempt from liability. The hospital further contended that it was not responsible for any alleged negligence of the nurses during the operation.

To determine the charitable status of a hospital, said the district court of appeal, it is necessary to consider not only the hospital's articles of incorporation and by-laws but also its method of doing business. The purposes for which the defendant hospital was formed, according to its articles of incorporation were "to acquire and maintain suitable and permanent convents, orphanages, hospitals and other charitable institutions." It treated pay and charity patients. If there was any surplus above operating expenses, it went to the upkeep of the institution and to educate young women to be teachers and nurses. The court accordingly concluded that the hospital was a charitable hospital and as such was not liable for the alleged negligence of its nurse and of the physician. The fact, the court added, that the patient was a pay patient did not alter the rule of law exempting a charitable hospital from liability.

Furthermore, continued the court, even if the hospital were not a charitable institution, it still would not be liable for the acts of the nurse which it furnished to the operating physician. During the preparation and progress of an operation the nurses in the surgery are under the control of the operating physician, and he, and not the hospital, is responsible for their negligence. *Schloendorff v Society of New York Hospital*, 211 N. Y. 125, 105 N. E. 92.

For these reasons, in effect, the district court of appeal ordered that judgment be entered in favor of the hospital but that a new trial be had as to the physician—*Armstrong v Wallace (Calif.)* 37 P. (2d) 467.

Workmen's Compensation Act Malpractice of Physician, Liability of Employer—Hughes, an employee, was awarded compensation by the workmen's compensation commission of Missouri for the aggravation of preexisting trachoma, through the accidental splashing of mortar into his eye. He signed a release discharging his employer and his employer's insurance carrier from liability under the workmen's compensation act. Later he sued them in a court of law, for aggravation of the original injury by the malpractice of the physicians employed by the insurance carrier. From a judgment by the trial court in favor of Hughes the employer and the employer's insurance carrier appealed to the Kansas City court of appeals, Missouri. They contended that the proximate cause of Hughes' injury, if any, by the physicians, was the original accident and that that injury was covered by the compensation paid to Hughes under the workmen's compensation act, that jurisdiction over Hughes' present claim was vested in the compensation commission and not in a court of law.

It is the well established principle of common law, said the court, that if the injuries of a person who is injured by the negligence of another are aggravated by the negligence of a physician employed in the exercise of ordinary care either by himself or by the person doing the injury, the negligence of the wrongdoer in causing the original injury is to be regarded as the proximate cause of the damage flowing from the negligent treatment by the physician. Furthermore, continued the court, while the theory of compensation is not recovery based on negli-

gence or wrongful acts of the employer, but recovery based wholly on the fact of employment, yet the overwhelming weight of authority is that in compensation cases the malpractice of a physician selected by the employer to treat the injuries of his employee is directly traceable to and a proximate result of the primary injury for which the injured workman is treated, and, if his injuries are aggravated by the negligence of the physician, compensation for such aggravation must be procured in the proceedings provided for in the workmen's compensation act. Concluding that Hughes' claim had no standing in a court of law, the judgment in his favor was reversed—*Hughes v Maryland Casualty Co. (Mo.)*, 76 S. W. (2d) 1101.

Compensation of Physician Liability of County for Fee of Physician Performing Emergency Operation on Pauper—In an emergency, says the Supreme Court of Nebraska, requiring an operation to save the life of a pauper, the operating physician should, if reasonably possible, attempt to communicate with the proper county authorities charged with the care of the poor, but if the situation demands an immediate operation, the necessary services may be rendered and the law imposes an obligation on the county to pay the reasonable value of such services. In this case, a pauper exhibited the symptoms of a rupture of some kind in the alimentary tract and was hurriedly driven by friends to the nearest hospital, which was out of the county of the pauper's residence. No attempt was made by the hospital to communicate with the authorities charged with the care of the poor in the county in which the pauper resided to secure authorization for an operation and for hospital service, but the patient was immediately operated on. A ruptured stomach was revealed and necessary hospitalization was rendered. The Supreme Court of Nebraska held the county of the pauper's residence liable for the operating physician's fee and for the value of the hospital services rendered—*Burnham v Lincoln County (Neb.)*, 257 N. W. 491.

Malpractice Injury to Spinal Accessory Nerve Incident to Removal of Branchial Cyst—One of the physician-defendants removed a branchial cyst from the right side of the plaintiff's neck, under local anesthesia. The patient, according to his testimony later, noticed immediately after the operation that the right side of his face was numb and shortly thereafter suffered pains, aches and discomfort in his right arm and shoulder and could not raise his right arm above his head. The wound healed promptly, but an incomplete paralysis and atrophy of the muscles of the right shoulder persisted, with about 25 per cent impairment of function. The patient then sued the operating physician and his copartner for malpractice. From a judgment in favor of the plaintiff, the defendants appealed to the Supreme Court of Oregon.

The plaintiff charged that the operating physician, one of the defendants negligently injured the right spinal accessory nerve and thus caused his disability. An expert medical witness called by the patient, whom he had treated, testified that in his opinion the spinal accessory nerve had been severed. The defendants and their expert medical witnesses thought that the nerve had not been severed, although it might have been bruised or otherwise injured, but the testimony indicated that if the nerve had been only bruised, regeneration should already have taken place.

The defendant who had performed the operation and one other expert witness were asked to state their opinions as to certain matters concerning which they had testified. To this the defendants objected claiming that expert opinions by physicians could properly be elicited only through hypothetical questions. But, said the court, when an expert is requested to express an opinion on facts observed by himself, which he has already related to the jury, the request need not be in the form of a hypothetical question. The jury can determine whether his conclusions are sound.

The defendants contended that there was no evidence to show negligence or to show that negligence, if there was any, was the proximate cause of the plaintiff's condition. But we have here, said the court, the testimony of a competent medical expert that the nerve had been severed, the operating physician's own admission that in removing a cyst such as was removed in this case it would be improper to sever the nerve unless by "accident," and that no accident occurred in the

course of this operation, and that a severance of the nerve would produce the condition found in the plaintiff after the operation. Thus, the court held, was substantial evidence competent to support the finding of negligence.

Finally, the defendants contended that a physician is not responsible for an unfavorable result when his method of treatment is one that is recognized as proper by at least a part of the medical profession. This rule, said the court, is not involved in the present case, since the patient did not criticize diagnosis or treatment. He claimed that during the operation the defendant who operated wrongfully severed a nerve, and apparently all medical men, including the operating physician himself, agreed that the severance of that nerve was improper. The jury determined that the nerve had been severed, which was in fact the sole issue in the case, apart from the amount of damages.

The judgment of the trial court in favor of the plaintiff was affirmed.—*Heider v Barendrick (Ore)*, 39 P (2d) 957

Malpractice Sponge Left in Operation Wound—The defendants removed the plaintiff's left kidney. In the course of the operation they used small sponges, so called "fluffs" and larger laparotomy sponges. After her discharge from the hospital, the patient did not recuperate as it was expected that she would, and Dr Hunsucker, her family physician, was consulted. He found the wound healed except where an opening had been left for drainage. He enlarged this opening and packed it with iodoform gauze, but the wound continued to give trouble. He called in Dr Shuford, who, on opening the wound its entire length and probing it found a sponge similar to the "fluffs" employed in the original operation. He threw this sponge away and repacked the wound but with gauze dissimilar to that in the sponges used in the original operation. A few days later Dr Hunsucker removed from deep in the wound another sponge of the "fluff" type. The patient, claiming that the operating physicians had left two sponges in her body, instituted this action for malpractice. From a judgment in her favor, the physician-defendants appealed to the court of appeals of Tennessee, eastern section.

At the trial, the defendants testified that they did not leave sponges in the wound. In this they were corroborated by the anesthetist and by a nurse. As there was only circumstantial evidence to show that they did so, the defendants argued that the suit should be dismissed because of the absence of evidence to support the verdict. The facts of the case however, said the appellate court made it incumbent on the defendants to do more than to deny positively that they left gauze within the wound, since it is conceded that it is negligence for a physician to leave gauze within a wound, the defendants must show before they can escape liability that some one else had an opportunity to place the gauze where it was found. The defendants insisted that the evidence did not exclude an inference that Dr Hunsucker might have packed gauze through the small opening left for drainage, and that the gauze removed by Dr Shuford was gauze packed in the wound by Dr Hunsucker. But, said the court of appeals, both Dr Hunsucker and Dr Shuford testified that they did not leave sponges in the wound and that the sponges found were not of the same type as the gauze or sponges used by them. Except for a bare possibility that Drs Hunsucker and Shuford left gauze in the wound there was no circumstance supporting the inference attempted to be drawn by the defendants and other proved circumstances negated this inference and supported the positive and uncontradicted testimony of Drs Hunsucker and Shuford. The court called attention to a letter written by one of the defendants soon after the first sponge had been removed from the wound in which he said

I am indeed greatly humiliated over the gauze being left in. Would you mind asking the doctor whether it was a gauze pack or a gauze sponge.

These unfortunate occurrences happen in the best hospitals but of course does not keep one from feeling very badly about such an accident.

It must be conceded, said the court that either one of the physician-defendants or Dr Hunsucker, or Dr Shuford left the gauze in the wound and the case presented therefore an issue for the jury to determine from the preponderance of evidence.

The court of appeals affirmed the verdict against the defendants, but only on condition that the plaintiff would consent to a reduction in the judgment from \$4,000 to \$2,500. Otherwise a new trial was to be granted the defendants.—*Barry v Maxey (Tenn)*, 75 S W (2d) 823

Evidence Opinion of Expert Based on Evidence Heard at Trial, Testimony of Expert Invading Province of Jury—In a will contest in which the mental competence of the testatrix was questioned, the trial court sustained the will and the contestant appealed to the Supreme Court of Michigan. A medical expert who had been present throughout the trial was permitted, over the objection of the contestant and without being interrogated in the form of a hypothetical question, to testify on the basis of all the evidence that he had heard at the trial as to the competence of the testatrix. Such procedure, said the Supreme Court, was error. It permitted the witness to put his own construction on the testimony that he had heard. Without a recital of the facts or assumptions embodied in a hypothetical question as a basis for the expert's answer, it was not possible for the trial court to make an intelligent ruling, or for opposing counsel to interpose timely objection, or for jurors to consider accurately the testimony given. The difficulty of testing the accuracy of the witness's declaration that he has heard and has in mind the testimony of all preceding witnesses condemned the practice, as such accuracy could be tested only by cross-examination, which in the average case would be so lengthy and tedious as to be intolerable. As authority for this holding the court quoted from 11 R. C. L. 581, reading, in part, as follows:

It may perhaps safely be stated as the majority rule that generally an expert cannot be allowed to base his opinion on the evidence which he has heard given in the case.

The same medical expert was permitted to testify also that all the evidence presented did not show that the testatrix was either mentally competent or mentally incompetent. Such testimony said the Supreme Court, was not permissible, as it allowed the expert in effect to say to the jury that the testimony of the expert witnesses who had preceded him was not entitled to any credence and therefore allowed the expert to usurp the function of the jury.

For these reasons the Supreme Court set aside the judgment of the trial court sustaining the will and ordered a new trial.—*In re Elliott's Estate Elliott v Collins (Mich)* 257 N W 919

Accident Insurance Death from Anesthesia—The plaintiff, as beneficiary, sued on a policy of insurance that provided certain benefits if the insured's death should result directly and independently of all other causes from bodily injury effected solely through external, violent and accidental means, but not if death resulted directly or indirectly from bodily or mental infirmity. Judgment was given for the defendant insurance company, and the plaintiff appealed to the United States circuit court of appeals, fifth circuit.

The plaintiff claimed that the insured died from bodily injuries effected solely through external violent and accidental means, in that an anesthetic was administered in the performance of an abdominal operation on the insured and the anesthetic though skilfully administered and ordinarily harmless, produced death because of an impairment of the insured's heart, which was unknown to the physician who administered the anesthetic. This condition of the heart the plaintiff claimed, was caused by an automobile accident that occurred shortly before the operation but the date of which was not stated. The use of the anesthetic, said the circuit court of appeals, was intentional and no mistake or slip is alleged in its administration. In addition to its usual and expected sedative results an unexpected result occurred, due to a heart weakness of short duration but antedating the operation. There was an accidental death caused in part by an external means that the means that caused death was accidental is not so plain. By the weight of authority, a means is not made accidental because some unexpected result follows, in addition to that which was intended to be accomplished. But irrespective of that, said the court, it is clear that the fatality cannot be said to have been effected solely by external violent means, because it was due also to the internal bodily weakness, with-

out which there would have been no death. This also was a "bodily infirmity" within the meaning of the exception in the policy, for infirmity includes abnormal weakness as well as acute disease. If a bodily infirmity, though unknown at the time, is a concurring cause without which death would not have resulted, the policy does not cover the case.

The judgment in favor of the insurance company was accordingly affirmed.—*Davis v. Jefferson Standard Life Ins. Co.*, 73 F (2d) 330

Hospitals Liability for Negligence of Special Nurse—An abdominal operation was performed on the plaintiff at the defendant hospital by a physician selected by the plaintiff. He was thereafter cared for by his own physician and by nurses employed by him or by his physician—and not by hospital employees. Some time later he experienced great physical discomfort. The operation incision was opened and a toothpick was found and removed. Later, cotton also was found in his body. He sued the hospital, alleging that the toothpick and cotton found their way into his body while he was in the hospital, as a result of the hospital's negligence in furnishing the nurses who cared for him with what are commonly termed "toothpick applicators", that is, toothpicks with cotton on each [sic] end for use in caring for his wound. From a judgment for the plaintiff, the hospital appealed to the district court of appeal, second district, division 1, California.

Both parties stipulated that it was the duty of the hospital to exercise ordinary care to furnish to the attendants of the patient suitable supplies, equipment and facilities commensurate with the requirements of his case, and to use reasonable care in providing the same for the use of those charged with his care and treatment. All the medical testimony, said the district court of appeal, was to the effect that the use of toothpick applicators with surgical dressings is a dangerous practice. Under the evidence in this case, can it be said that the injury which the plaintiff suffered was a natural or probable consequence of the act of the hospital in furnishing the toothpick applicators? In this case the persons who used the applicators were trained nurses employed by the plaintiff. They are members of a profession which the law recognizes as one of skill and learning. The hospital, if it furnished the toothpicks as the plaintiff contends, sent them to a professional employed by the plaintiff to care for him. If she used them with injurious consequences, her act was certainly one of a responsible and intelligent person, which relieves the defendant of any liability which might be created by its primary negligence.

The duty of the hospital to furnish suitable supplies and equipment, continued the court, does not make the hospital liable for furnishing articles which a trained nurse should know, from training and experience and the standards of care ordinarily used in her profession, are dangerous. If the article furnished is obviously unfit for the use for which it is furnished by the hospital, and the plaintiff's employee uses it in violation of all the standards of care of nursing practice, the defendant cannot be charged with any injurious effects from it.

The judgment in favor of the patient was accordingly reversed.—*Payne v. Santa Barbara Cottage Hospital (Calif.)*, 37 P (2d) 1061

Dental Practice Acts "Advertising" Not Synonymous with "Soliciting"—The dental practice act of North Carolina authorizes the state board of dental examiners to revoke the license of any dentist "guilty of false notice, advertisement, publication, or circulation of false claims, or fraudulent misleading statements of his art, skill, or knowledge, or of his methods of treatment or practice or [who] has by himself or another solicited professional business." Proceedings were instituted to revoke the license of a dentist, the respondent in this case, under an accusation charging him with soliciting professional business by paid advertisements in the newspapers and by signs in colors and of large dimensions on the building in which his office was located. The board revoked his license and, from a judgment of the superior court upholding the board's action, he appealed to the Supreme Court of North Carolina.

The dental practice act, said the court, inveighs against two offenses (1) false advertising, and the circulation of false

claims or fraudulent or misleading statements, and (2) soliciting professional business. There was no charge of false advertising or of the circulation of false claims or fraudulent or misleading statements. This appeal therefore raises the question only as to whether the use by a licensed dentist of paid advertisements of his work and prices in newspapers with a large circulation, and of signs in flaring colors and of large dimensions, constitutes such soliciting of professional business as is inhibited by the dental practice act. Advertising and soliciting are not synonymous terms. If they were so, every dentist who inserted a professional card in a registry directory or other publication, and paid for such insertion, or who placed on the window or door of his office, or on the wall of the building in which his office is located, his name, followed by the word "dentist," would subject himself to an accusation that might lead to the revocation of his license. The act makes unlawful only the use of false advertising and the circulation of fraudulent and misleading statements, and the corollary follows that the use of truthful advertising and the circulation of truthful statements are not unlawful. The record contains no suggestion of any soliciting by the respondent otherwise than by advertising in newspapers and by signs.

The court expressly refrained from passing on the ethics of the advertising resorted to by the respondent and suggested that if the North Carolina board of dental examiners desires further to limit the nature and extent of the advertising to which members of their profession may lawfully resort, their remedy lies with the legislature and not the courts. The law making branch of the government, the court said, if in its wisdom it saw fit, might make unlawful any kind of advertising by members of the dental profession, whether false or otherwise. For the reasons stated, the judgment of the superior court, upholding the action of the board in revoking the respondent's license, was reversed.—*In re Owen (N. C.)*, 177 S E 403

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Lesions in Pulmonary Artery and Aorta in Rheumatic Fever—Gross describes the lesions found within the roots of the pulmonary artery and aorta proper in 150 hearts, i. e., the purely musculo-elastic portions, as well as within the vessels found in their enveloping pericardial mantles. Sixty-six cases presented active rheumatic fever as manifested by the presence of fibrinous pericarditis, acute verrucous endocarditis, Aschoff bodies, eosinophilic collagen changes (fibrinoid) and other inflammatory phenomena in the myocardium. Thirty-four cases represented inactive rheumatic material, according to the criteria formulated by Rothschild, Kugel and Gross. The remaining fifty cases were from a nonrheumatic control series representing various age periods from birth to the ninth decade of life. This series was carefully selected to eliminate past or present hypertension, since this condition is associated with vascular changes in the periaortic and peripulmonic sheaths. After fixation of the heart in a 10 per cent neutral solution of formaldehyde sodium chloride, blocks were cut according to the standardized method of Gross, Antopol and Sacks. Sections were cut from each block and stained as a routine with hematoxylin and eosin and with Weigert's elastic and Van Gieson's connective tissue stains. An unexpectedly high incidence of capillarization was observed, both of the pulmonic and of the aortic roots. This occurred in 70 per cent and more of inactive as well as active cases, as compared to 25 per cent of the control non-rheumatic series. Not infrequently the capillaries were larger, more irregular and of wider distribution in the rheumatic series. It appears that the very florid inflammatory and destructive phenomena in the aortic root, together with the somewhat different observations in the pulmonic root and its pericardial sheath, serve to differentiate histologically syphilis from rheumatic fever. All the active rheumatic cases presented in the peripulmonic sheaths either a microscopic pericarditis or an acute exudative pericarditis, and in the inactive rheumatic series many cases showed scattered lymphocytes and large mononuclear cells in this area. It seems possible that this inflammatory condition of the pericardial mantle bears a causal relation to the markedly increased capillarization of the great vessel roots. At any rate, this mechanism must be considered a factor in addition to spread of the irritative agent by way of the vasa vasorum (Klotz) and by way of the main blood stream (Pappenheimer and VonGlabn). While scarring is not a conspicuous

feature in the pulmonic root in rheumatic fever, it becomes extremely important in the aortic root, in which the lesions may be so extensive as to be confused with syphilis. In such instances the damage may undoubtedly express itself functionally by producing diminished resilience and elasticity of the great vessel roots. The finding of inflammatory lesions in 20 per cent of aortic roots in the active rheumatic series was not unexpected, even though the 6 per cent incidence of intimal verrucous lesions was certainly more than anticipated from gross observations. On the other hand, the 14 per cent incidence of inflammatory lesions in the pulmonic root, with one case showing a verrucous lesion of the intima, was surprisingly high and of considerable interest. The intimal reduplications are important histologically only when they are quite fresh and serve to indicate the presence of activity. The vascular lesions in the peripulmonic and periaortic mantles are similar to those described by Gross, Kugel and Epstein. The considerable increase in these lesions both in active and inactive cases is in keeping with the observations in the coronary ramifications within the myocardium proper. The somewhat lower incidence of the more characteristic lesions in the pulmonic and aortic roots of the inactive as compared to the active rheumatic fever series indicates that some of them may heal with little discernible residues, that some may become transformed into the less characteristic alterations seen in the control series due to age period changes, and that the more marked lesions probably occur in patients so violently afflicted with the disease that many fail to reach the inactive stages.

Neuropathology of Experimental Vitamin Deficiency—Gildea and her associates state that seventeen dogs given a diet deficient in vitamin B (Cowgill) developed signs of acute disturbance of the central nervous system and died without treatment with vitamin B concentrates. Only minimal histologic changes were found in the central nervous system. Eight dogs given a similar diet, but whose acute neurologic signs were repeatedly and temporarily relieved with vitamin B concentrates, developed gradually a residual degree of spastic ataxia and eventually motor paralysis, with reflexes present. Definite histologic lesions of the central nervous system were found in all but one animal. Nissl stains of the cerebral and Purkinje cells and of the ventral horn cells revealed evidence of degeneration. Weigert-Pal stains of the spinal cords showed definite losses of myelin in seven dogs. The peripheral nerves of three dogs showed an increase of material staining with scarlet red or with the Marchi technic. The results of observations on the effect of partial starvation, of supplements of cod liver oil and of therapy with dried yeast on morphologic changes in the central nervous system were rendered inconclusive, probably because the basic deficiency was not sufficiently prolonged to produce morphologic changes in the nervous system of any of the animals.

Radium Dosage in Carcinoma of the Tongue—Simpson discusses the technic and dosage that he is employing in the treatment of carcinoma of the tongue. The application of radium to the surface of the tongue lesion is inadequate to

accomplish a clinical cure necessitating the implantation of radium or radon. In the average case of squamous cell carcinoma of the tongue with cell nests, which is radioresistant, the practice of implantation should be continued. Lymphocytic and transitional cell cancer without cell nests, which are radio-sensitive, sometimes recede greatly or even disappear for a time under the influence of surface irradiations only. It seems safer to implant every carcinoma confined to the tongue, unless it is too extensive, regardless of its pathologic type. The implantation method in general should be limited to rather small, well circumscribed, favorably situated lesions, in which there appears great probability that radium or radon may be successfully implanted in every part of the growth and in which surface irradiation or excision has been generally found to be inadequate or inadvisable. If every part of a given neoplasm can be reached with tubules and the attendant conditions are favorable, a clinical cure frequently results. If every part of a given tumor cannot be reached and the attendant conditions are unfavorable, it is unwise to subject patients to a procedure that is somewhat heroic and painful, when it does not promise complete eradication of the disease. Success in radium therapy of carcinoma of the tongue depends largely on meticulous attention to a chain of details: roentgenograms of the lower jaw and chest, syphilis and diabetes are unfavorable factors in the radium treatment of carcinoma, hygienic condition of the mouth and teeth representing foci of infection. The author prefers to delay all ordinary disinfecting measures until the growth has been treated with short, powerful applications of radium. His discussion of the technic and dosage includes biopsy, the primary lesion, indications for implantation, methods of implantation, lead tubules, pitfalls, control of pain, protection of bone, metastases, nonpalpable and palpable nodes.

Dietary Errors in Connection with Radium Treatment

—Believing that a study of the diets of persons suffering from various kinds of tumor might be valuable, Quigley began an inquiry in 1922 and continued it through 1932. The number of patients involved was 2,707. Inquiry was made as to the food habits for as far back as the patient could remember and the relative amounts of various foods noted. In checking the cases, it was found that all were on more or less deficient diets and that none had cancer as a single disease. The deficiencies were in calcium, vitamins and iodine and cellulose, the concurrent diseases were those of the heart and blood vessels, the joints and the gastro-intestinal tract, with a few having cataracts and between 5 and 6 per cent diabetes. Obesity was a factor in more than 30 per cent of the cases. Many of the patients had been operated on for gallbladder disease and a large percentage were suffering occasional gallbladder colic, 95 per cent suffered from constipation or some form of stomach or intestinal disease. Some of the diets taken by these patients were almost completely composed of refined carbohydrates, an occasional salad being the only normal food eaten. The food consumed showed universal deficiencies in calcium, iodine and iron. Vitamin deficiencies were shown by certain signs and symptoms. The author has found the optimal requirements of vitamin A for adults to be 2 quarts of whole milk or its equivalent, for vitamin B 2 drachms (8 Gm) of dried yeast or its equivalent, for vitamin C 12 ounces (360 cc) of orange juice or its equivalent, and for vitamin D such an amount as may be represented by one hour of midday sun at half season or 2 drachms (8 cc) of cod liver oil. Unless a sufficient amount of calcium is present, vitamin D is likely to prove irritating to the nervous system. If a sufficient amount of cellulose in its natural state is taken as implied under the term equivalents, there is no room left for any refined carbohydrates. It is important that sugar and patent flour products be eliminated, as these furnish energy and high calories without necessary physiologic concomitants, minerals, cellulose and vitamins. Table salt should also be eliminated and replaced by a mixture of salts corresponding to those in Ringer's solution. Patients with external accessible malignant manifestations who have followed this regimen have had 20 per cent less recurrences, have been relieved of the unpleasant effects of concurrent diseases and have enjoyed increased energy and freedom from fatigue, the most striking examples of benefit being in cases of associated arthritis, gastro-intestinal troubles and obesity. In this connection, no case of carcinoma showed

any material improvement until the diet was so arranged that sugar disappeared from the urine. Therefore every person should be studied from the standpoint of the organism as a whole and all necessary dietary corrections made.

Arsphenamine Poisoning in Negro Women.—Walsh and Stickley believe that arsphenamine poisoning in the Negro differs in many ways from the same type of poisoning in the white race. Of fourteen cases of arsphenamine poisoning admitted to the Employees' Hospital in five years, eleven occurred in Negroes. The fact that the symptoms and skin changes in the Negro do not receive the attention that they do in the Caucasian is believed to be one reason why these cases are not discovered by the physician in time to prevent an occasional fatality. The mental attitude of the Negro, marked by disinterestedness, secretiveness and a certain callousness toward his own suffering, is believed to be another reason why the treatment is persisted in until the poisoning has become an accomplished fact. The fragility and small caliber of the veins of the Negroess and the difficulties incident to giving the arsphenamine without spilling into the perivenous tissue are suggested as reasons for the frequency of arsphenamine poisoning in the female sex. Eosinophilia was a common observation. Whether or not its presence is an expression of an allergic phenomenon the authors do not know. The effects of epinephrine in allaying the itching were almost miraculous and suggested an underlying allergy.

Antiserum Treatment of Brucellosis.—Wherry and his co-workers produced antisera for the initial therapeutic trials from goats after subcutaneous inoculations with chemically treated suspensions of Brucella. The sera used during the first year represented six strains, one bovine and five porcine. At the beginning of the second year five melitensis strains were added. During the past year the authors have adopted a total amount of 60 cc., usually given in three daily injections of 20 cc. each, as the average adult dosage for infections of average severity. Unconcentrated serum has been given by vein, intramuscularly and subcutaneously. It is clear that some of their first patients did

not receive enough serum. Serum sickness has been infrequent and usually mild. Of their twenty patients who responded favorably to serum therapy, the indicated averages are significantly encouraging. After serum therapy the average duration of fever was nine days, the average duration of symptoms was fifteen days and the average duration of disability was three and a half weeks. The average total disability period was two and three fourths months, and the average time at which serum therapy was begun was at one and nine-tenths months. Hence two thirds of the total disability period represents elapsed time of illness before serum was given. There were six cases that were either doubtfully improved or clearly unimproved by serum therapy. One doubtfully improved patient was a man with an unusually severe infection, with continuous high fever, profound prostration, severe anemia, a palpable spleen and an enlarged liver with intense general icterus. In three of the patients, who had either bland or extremely slight, transient, favorable responses, the disease had existed for a year or more before treatment was begun. Experience with serum therapy in tularemia has taught the authors that the chronic infections due to *Bacterium tularense* are most frequently not modified by serum therapy. The possibility of a similar refractory state in chronic brucellosis must be considered. They consider the time of administration an important factor in successful therapy and think it advisable to use it early in the course of illness, preferably before the end of the fourth month of symptoms. The effect of serum therapy on the fever curve was usually shown by a fairly prompt fall in temperature to normal, accompanied by a rather well marked antitoxin-like response characterized by an amelioration of myalgias, arthralgias, headache, gastric symptoms and general subjective discomfort including sweats. The chief therapeutic action of the antiserum is very probably its capacity to induce specific phagocytosis.

Aqueous Smears in Identification of Ameba—Hakanson presents the observations of the trophozoites of *Endamoeba histolytica*, *coli* and *nana* and of *Diandamoeba fragilis* that he has observed in aqueous smears. The observations indicate that certain features in the morphology of the ameba can be demonstrated in the aqueous medium: (1) the distensibility of the ectoplasm of *Endamoeba histolytica*, (2) the relative fragility of the ectoplasm of *Endamoeba coli* and *nana*, (3) the resilience of the ectoplasm of *Diandamoeba fragilis* and (4) the remarkable strength of the nuclear membrane of *Endamoeba histolytica* and *coli*. Some of these characteristics together with the visibility of the nuclei help to differentiate the species of ameba in the human stool. The annoyance of *Blastocystis hominis* can be eliminated by the use of the aqueous smear.

True Papilloma of Nasal Cavity—An analysis by Kramer and Som of the literature reveals the fact that at least four distinctly different types of tumors have been included under the heading of papilloma. These are 1 Mucous polyps, or soft papillomas (Hopmann). The true inflammatory nature of these growths can no longer be questioned regardless of their epithelial lining. While these polyps are lined most frequently by columnar epithelium, metaplastic changes with transition to squamous epithelium are not uncommon. Such changes are undoubtedly associated with external physical chemical and inflammatory processes in the nasal chambers. 2 Innocent cutaneous warts arising from the vestibule of the nose, especially on the antero-inferior portion of the septum. They are localized slightly elevated, papillary epithelial hyperplastic lesions surrounded by an area of normal mucosa. They can be removed

with ease and show no tendency to recurrence. The literature contains records of numerous instances in which such lesions have been reported erroneously as true papillomas of the nose. 3 Papillary carcinomas, which are malignant neoplasms that possess invasive characteristics and tend to metastasize to regional lymph nodes. These tumors are often referred to as malignant papillomas. Although their development on the basis of a true papilloma is a possibility, they should be classified with the carcinomas. Only a small percentage of the growths heretofore reported as papilloma fall into the category of true papillomas. Papilloma durum is a true nonmalignant neoplasm of epithelial origin and should not be confused with the preceding types. Papilloma durum appears in the form of grayish red indurated papilliferous new growths, which bleed readily on manipulation. Their hardness is primarily dependent on the marked proliferation of the epithelial tissue. These neoplasms arise from the nasal accessory sinuses and the deeper structures of the nasal cavity. They readily involve a large area of mucous membrane and may attain a huge size. Their tendency to multiple recurrences and malignant transformation is characteristic.

Aberrant Pancreatic Tissue in Gastro-Intestinal Tract.—Branch and Gross report twenty-four other cases in which aberrant pancreatic tissue was found in various locations in the wall of the alimentary canal. In three instances the tissue was found in the stomach or pylorus, in ten, in the duodenum (in one in a duodenal diverticulum) in four, in the jejunum, in one, in the ileum, and in six in a Meckel diverticulum. These structures contained ductal and acinar elements the histologic structure of which closely resembled that of normal pancreatic tissue. In fifteen specimens there were no islets of Langerhans in the sections studied, but in the other nine cases there were typical islets. The age of the patients in whom the

anomalous tissue was found varied from 8 days to 82 years. The cases occurred in equal numbers in males and in females. The presence of this aberrant pancreatic tissue in the gastro-intestinal tract probably represents a congenital anomaly in most, if not in all, instances. Four of these twenty-four cases had important pathologic significance. In one of these the nodule caused pyloric obstruction, and in the other three it was the site of ulceration in the stomach or duodenum. Such a nodule in the wall of the gastro-intestinal tract has been mistaken for carcinoma. The gross appearance of the tissue should indicate that it is pancreatic in type and should obviate the danger of unnecessary removal when it is not the cause of intestinal obstruction or the site of an important pathologic lesion.

Ulcerative Colitis—Dack and his associates observed that the isolated colons of the three patients in whom ileostomies had been performed contained at first many species of organisms in large numbers. After some months the flora became largely anaerobic. In all three cases the same type of organism eventually predominated, it closely resembled *Bacteroides fragilis* and *funduliformis* (Thompson and Beaver), *Actinomyces necrophorus* (Shaw, Cunningham) and *Bacillus necrophorus* (Orcutt). This organism was pathogenic to rabbits and, following subcutaneous injections of large amounts of culture, produced local abscesses, which tended to heal after a long time. The organisms isolated were similar to the necrophorus organisms. In mediums they produced a putrid odor resembling that of butyric acid. They grew well on blood agar and serum dextrose mediums and in dextrose mediums to which a small amount of cystine was added. Exposure to oxygen was highly lethal in a short period. Complement-fixing antibodies have been demonstrated in the serum of four patients with ulcerative colitis, with antigen prepared from the predominating anaerobic organism cultured from the isolated colons of two patients. Very slight fixation of complement occurred with an antigen of monkey origin. The serum of one young adult without a history of intestinal lesions gave slightly positive results, whereas the serum of four other healthy young adults gave negative results. The serum taken from one patient gave a negative reaction. This result is difficult to explain in view of the agglutination reactions, which were positive. There was extensive disease of the intestine in the four cases in which the serum gave positive reactions. The complement fixation tests with the serum of the three monkeys tested were all positive, but in varying degrees. Agglutination tests were performed, the serum of five patients with ulcerative colitis against strain 40 being used. Agglutinins were present in all this serum. The serum from three healthy persons contained no agglutinins for this strain, whereas the serum from a fourth healthy person contained only a trace of agglutinins and then only in the strongest dilution of serum. Bacteriologic and serologic studies in a larger series of cases of ulcerative colitis may help to evaluate the significance of the organism described.

Peptic Ulcer Following Experimental Jejuno-cystostomy—McMaster performed duodenocystostomy on twenty dogs without resecting the intestine between the points of duodenal transection and anastomosis into the colon in an endeavor to determine how often peptic ulceration occurred after jejuno-cystostomy both with and without retention of the intestine between the points of anastomosis and, if possible, what the etiologic factor might be. He found that, following jejuno-cystostomy in which the distal portion of the jejunum and the ileum were left in place as a blind stump, acute, subacute or chronic peptic ulceration developed in thirteen dogs operated on. Three of the ulcers perforated the wall of the intestine, leading to peritonitis. In three dogs on which duodenocystostomy was performed, the distal portion of the duodenum, the jejunum and the ileum being left as a blind stump, peptic ulceration was not observed. When a jejuno-cystostomy was performed with resection of the intervening intestine, peptic ulceration occurred in two of eleven dogs operated on. A rather marked loss of weight occurred in nearly all these animals, but this did not seem to be the etiologic factor responsible for the peptic ulcers. Gastritis and duodenitis, as evidenced by inflammatory reaction in the surrounding walls of the stomach and duodenum, seemed to follow rather than precede the peptic ulceration, as nearly as could be determined by microscopic studies.

Study of Spermatogenesis of Undescended Testicles—MacCollum studied the fertility of eighty-nine men with undescended testicles. He forms three conclusions: 1. Except in a small percentage of cases, the fertility of all persons with cryptorchidism seems to be lower than that of the normal person. 2. The cosmetic result after orchiopexy cannot be used as a criterion of fertility. 3. In eighteen patients with bilateral undescended testicles on whom orchiopexy had been done there was definite fertility in eleven, and in three more, in whom the counts were lowered but active sperm were present, potential fertility. The proportion of definite fertility in persons who have undergone orchiopexy may then be computed as 61 per cent, in contrast to the estimated 10 per cent in persons without orchiopexy. In the author's opinion these statistics definitely make orchiopexy a justifiable procedure. His main purpose has been to stimulate an interest in other clinics to carry out a similar type of investigation. He is continuing the investigation and hopes to correlate the types of orchiopexy with the resulting spermatogenesis.

Studies on Scarlet Fever Anatoxin—Ando and Nagata observed that antigenicity of the so-called scarlet fever anatoxin produced by detoxifying scarlet fever toxin with formaldehyde and heat is due to presence of toxoid. Rabbits can be used for the determination of antigenicity of scarlet fever anatoxin. The antigenicity of the purified and concentrated scarlet fever anatoxin has been demonstrated by animal and human test. The antigenicity of the anatoxin prepared from scarlet fever toxin produced in a semisynthetic medium has been demonstrated. The addition of alum seems to increase the antigenicity of scarlet fever anatoxin. The degree of immunity conferred on rabbits by immunization with combined scarlet fever and diphtheria anatoxin is as high as that conveyed by a single anatoxin.

Blood Sugar Curves in Mental Disorders—Katzenbogen and Muncie obtained repeated blood sugar curves during the course of various psychoneurotic and psychotic conditions. On many occasions, improvement in the curve coincided with improvement in the mental state. Discrepancies between the former and the latter, however, were not infrequently observed: (1) normal blood sugar curve associated with quite marked emotional reactions, (2) anomalous curve paralleled by average spontaneous activity, (3) relapse in the blood sugar curve coinciding with clinical improvement and (4) relapse in the patient's condition accompanied by improvement in the blood sugar curve. No correlation could be established between the blood sugar curves and the various kinds of emotional reactions considered separately. The explanation for this is that in the authors' patients emotional manifestations did not present themselves separately but always in more or less inclusive combinations. If, in some of their patients one or another kind of emotion stood out conspicuously, it also was accompanied by other emotional reactions. In these patients no specific types of curves were obtained that could be attributed to one or another apparently predominant emotional manifestation. The study suggests that the relationship between blood sugar curves and various kinds of emotions in human beings can be adequately studied only under experimental conditions in individuals in whom particular emotional reactions can be provoked separately, and in individuals who, under the influence of certain occurrences equivalent to experiments, will display rather single specific emotions.

Antirachitic Properties of Irradiated Evaporated Milk.—Strong and his co workers fed twenty-two normal, artificially fed infants living in poor to middle class homes, irradiated evaporated milk without any additional vitamin D. The period of the study embraced approximately the first six months of life of the individual infants. A control group of eleven normal infants was fed a formula of whole cow's milk, with from 10 to 15 drops (0.6 to 1 cc.) of viosterol daily or 4 tea-

spoonfuls of plain cod liver oil as the source of vitamin D. The average daily consumption of evaporated milk ranged from 6 ounces (180 cc.) in the 1 to 4 week group to 16 ounces (480 cc.) in infants 6 months of age or more, giving a variation of from 266 to 589 units in the average vitamin D content of the food. Roentgenograms of the forearms of the twenty-two infants fed irradiated evaporated milk, taken at approximately 6 months of age, showed "slight evidence of rickets" in two of the infants. None of the infants in the control group showed roentgen evidence of rickets. Irradiated evaporated milk containing 38 Steenbock units to the ounce offers a source of vitamin D in an amount sufficient to reduce greatly the incidence or severity of rickets among patients whose parents either have not been educated to the necessity of antirachitic supplements to the food of all babies or who cannot afford them. As yet the irradiation of evaporated milk should not be relied on exclusively to provide protection to all infants throughout the first year of life. It should be supplemented with additional vitamin D units in the early months of life when the intake of irradiated evaporated milk may be insufficient to provide the unitage necessary to protect the infant.

Endocrine Studies in Children.—Gordon and Kuskin present a statistical study of the time of onset of teething, walking and talking in endocrine disturbances and of the relationship of intelligence to the developmental rate. Of 570 children studied, 369 presented evidence of endocrine disturbance and 201 manifested some degree of mental retardation without any sign of endocrine dyscrasia. The endocrine group is almost evenly divided into those with normal intelligence and those with mental retardation. 1 The time of onset of teething, walking and talking depends on four factors: the functional activity of the thyroid and of the growth hormone of the anterior pituitary lobe, nonendocrine factors, such as racial stock, familial tendencies, chronic conditions (such as rickets), acute infections, the mentality of the infant in the first 6 months of life, and the chronological relationship between time of inception of the influencing factor (endocrine or nonendocrine) and the normal time of teething, walking and talking. 2 In a mentally normal child, the time of onset of teething, walking and talking may serve as a criterion of endocrine function. Delay in the appearance of one or all indicates endocrine disturbance, provided all possible nonendocrine factors are excluded. 3 In a mentally retarded child, the time of onset of teething, walking and talking cannot be considered a diagnostic criterion of endocrine disorder. 4 Teething is within normal age limits in mentally normal children with adiposogenital dystrophy, thyrotoxicity and hypothyroidism. In the pituitary group there seems to be a relationship between the time of onset of teething and general growth. Dentition is delayed to the greatest extent in anterior pituitary deficiency of growth and in childhood myxedema. Premature teething was noted in 22.4 per cent of the pituitary cases. The time of eruption in hypothyroidism depends on the relationship between time of inception of the dyscrasia and normal teething time and also on the mentality of the infant in the first six months of life. 5 Unaided walking appears in mentally normal infants at about the same average time in all endocrine conditions except hypothyroidism in which there is a slight delay. 6 The onset of talking is within normal limits in mentally normal children in all pituitary conditions and is slightly delayed in hypothyroidism. 7 Infants with mental retardation teethe, walk and talk later than mentally normal infants in the same endocrine groups. Those with mental retardation due to nonendocrine antenatal factors, such as mongolism, congenital syphilis and microcephalus, teethe, walk and talk later on the average than those with postnatal disorders, such as epilepsy, encephalitis or brain injury. Considered as two groups, children with nonendocrine mental retardation teethe, walk and talk later than those with endocrine disorders. 8 The relationship between endocrine conditions, mental retardation and delay in onset of teething, walking and talking may be as follows. All may be expressions of some common factor present during antenatal or neonatal life. The glandular disturbance may be the cause of the delayed developmental rate and/or the mental retardation. The delay may be due to the mental retardation irrespective of the existing endocrine disorder.

Atypical Leukemic States and Leukemoid Reactions—Rubnitz presents four atypical cases of leukemia in which an individual hematologic picture was observed. From their study he concludes that malignant tumors of lymphoid tissue may establish a free communication with the circulation, tumor cells are fed then to the blood stream from such a focus. The cellular composition of the blood in such cases may be that of normal blood with the added tumor cells. The tumor cells may vary in their makeup in the same way as different lymphosarcomas vary histopathologically. The blood, on examination, may have the appearance of leukemic blood. There is, however, this basic difference. In true leukemias one is dealing with a primary disturbance of the hematopoietic system as a whole and, because of that, all the elements of the blood are affected, whereas, in the blood dyscrasias on a lymphoid tumor basis abnormalities only in the lymphoid elements may be seen, the rest of the cellular constituents of the blood are not affected. Of course, sooner or later, a situation is reached in which the hematopoietic tissue as a whole is invaded by the malignant cells and a picture of frank leukemia may set in. The author's first three cases exemplify atypical leukemic states superimposed on the basis of lymphosarcoma. Epithelial tumors ordinarily do not affect the cellular composition of the blood alone. A breaking down epithelial tumor may bring about puzzling bizarre changes in the blood.

Treatment of Some Vascular Disturbances of the Extremities—Cohn states that in the treatment of occlusive vascular disorders all measures which attempt to cure a symptom or manifestation which is local in character are basically wrong from a physiologic standpoint. The fundamental factor of importance is that manifestations of nutritional disturbances, such as acrocyanosis, claudication and gangrene, are local evidences of a general disease. Developments in the treatment of occlusive vascular phenomena, whether spastic or oblita-

tive in character, have followed many leads, some physiologic, others as by-products of increased knowledge of the sympathetic system. The author states that, believing that simple physiologic methods applicable to all extremities with ease offer hope of relief from pain and possibly the saving of limbs, he tried the method of passive vascular exercise. He found that it is by no means a cure-all, it does help and probably has prevented several amputations, favored healing of sluggish wounds, and in several instances made it possible for patients formerly crippled and incapacitated on account of pain to go back to their usual occupations. He asserts that vascular disturbances of the extremities are merely local manifestations of a general disease. When obliterative or organic disease of the vessels exists, local operation such as ganglionectomy does not offer more than relief of pain of a particular part. It cannot cure a disease in which the changes are to be found in every part of the vascular tree, as evidenced by the fact that many of the patients who die of Buerger's disease die with evidence of coronary disease. At necropsy this has been shown to be identical with the condition found in the extremities. If collateral circulation can be improved and pain relieved by methods that cause a dilatation of the peripheral vessels and thus help establish a collateral circulation to prevent gangrene, such methods should be used by preference over operations of considerable magnitude, the value of which has not been proved and which have been in use too short a time to show any ultimate results beyond the fact that some of them have resulted in failure. In the after-care of patients who by reason of an operation or an embolic process have had a sudden interference with circulation in an important trunk vessel the immediate value of a simple procedure such as passive vascular exercise is to be preferred to either ganglionectomy or blockage. The mechanical treatment for obtaining passive vascular exercise as suggested by Herrmann and Reid offers one of the most valuable contributions to the treatment of nutritional disturbances of vascular origin that have thus far been devised.

Artificial Pneumothorax in Treatment of Lobar Pneumonia—Robbins believes that artificial pneumothorax is a therapeutic agent of great value in the symptomatic treatment of lobar pneumonia as revealed by the results obtained in five cases. The amelioration and the alleviation of symptoms were prompt and permanent. In one case the specific action of the procedure was evidenced by the induction of an artificial crisis. The small number of cases treated and the admission of the patients to the hospital rather late in the disease prevented the possibility of more proof concerning this feature of the treatment. It cannot be gainsaid that artificial pneumothorax is a therapeutic agent that appears to be a great boon to the physician in the treatment of lobar pneumonia. The author states that at present artificial pneumothorax must be considered as one, though a most important one, of the several agents employed to combat this disease. The use of this treatment in pneumonia necessitates the warning that, unless one is experienced in the use of artificial pneumothorax, it is better to refrain from its employment because of the dangers attendant on its use and the added dangers of damage to the pneumonic lung.

Bacteriologic Studies of Epidemic of Diarrhea—During September, October and November 1934 Terrell and Owen observed an epidemic of diarrhea affecting infants, children and adults in Fort Worth, Texas and its surrounding territory. In Fort Worth alone the number of cases was well into the thousands, cases in infants and children predominating. Etiologic studies of the diarrhea epidemic were made by physicians in private practice, clinical laboratories and, to a certain extent by the city health department. Water, milk and food supplies were carefully investigated. The diets of the infants had been varied, some being fed powdered milk and others evaporated milk many had boiled cow's milk and a number were breast fed. Clinically the condition simulated Sonne's dysentery to such a degree that cultures of stools and agglutination tests of the blood for this condition, Hiss-Y Duval Shiga Flexner dysentery and the typhoids were made in fourteen cases all were negative. Almost all the cultures made from fresh stools showed a predominance of large gram positive diplococci that were neither hemolytic nor green producing. These cultures were best obtained from the freshest stools. In a few instances the first transplants showed practically pure cultures of streptococci. Stools from thirty patients exhibited streptococci as the predominating organisms sixteen of these were examined for fermentation. All the cultures fermented dextrose, lactose, maltose and sucrose, and all except one fermented mannite. The diplococcus in these cases differed from Bagen's diplococcus in that all the cultures except one fermented mannite. Cultures from twelve of the patients were given intravenously to rabbits (20 cc of a twenty-four hour culture) seven of which showed lymphoid hyperplasia and hemorrhages in the mucosa of the colon with superficial ulcerations similar to those seen in the intestine of the babies on whom necropsies were done. One of the experimental animals exhibited lymphoid hyperplasia and a congested intestinal mucosa with a very large amount of mucus but no ulcerations four exhibited no gross changes. Eight of the rabbits had

bloody mucus in the stools. The colon of one rabbit was filled with clear, light yellow, jelly-like material. Cultures from the ulcers and intestinal contents showed gram-positive diplococci that had the same cultural characteristics as those isolated from the patients. The treatment of the patients in this epidemic consisted of isolation, as the diarrhea was probably transmitted by direct contact. For the dehydration, abundant fluids were given, consisting chiefly of Hartman's solution by hypodermoclysis, intraperitoneally and intravenously. The infants were given fat free milk with a moderate amount of carbohydrates and increased proteins. The older children were given skimmed milk, bananas, banana powder and case. Opiates were given only when the stools became too frequent. Enemas of physiologic solution of sodium chloride or sodium bicarbonate relieved the tenesmus and seemed to hasten recovery.

Chronic Cystic Mastitis—Harvey points out that there is a sharp line of demarcation between carcinoma and cystic mastitis. In the former the natural history of the disease is that of a malignant state, in the latter of benignity. The histologic picture of the benign lesion, particularly during the most active phase of physiologic hyperplasia, often gives the impression that the epithelium is about to plunge through the barrier of the membrana propria and establish an invasive focus of cancer. The histologist hesitates to call such a picture benign, an equivocal answer may be found in terming it "precancerous," in which case he is always right whatever the later course of the disease may disclose. Bloodgood has pointed out that, when the proliferating epithelium is not unquestionably and readily seen to be invasive, the lesion is benign. Therefore, a true malignant condition does not simulate benign disease, whereas many forms of benign disease may suggest histologically the malignant. The fallacies of the determination of the incidence of cancer in chronic cystic mastitis are twofold: one is the assumption that the diagnosis of microscopic cancer is valid, the other that the sampling of instances of this cystic disease is a fair one and therefore that the incidence of cancer is high. One cannot emphasize too strongly the difficulties of a differential diagnosis in a situation in which an error may be fatal. In the generalized disease without an individual tumor or definite localization, the chances of error are so small that operative attack is unjustifiable. But when there is a definite tumor or a localized area of disease, the error of diagnosis increases to the point at which actual examination of the excised tissue must be obtained. Hart has followed up a borderline group which is supposedly most malignant in potentiality that is the intracystic papillomas. It seems that about 20 per cent of this so called borderline group are malignant and that the error of clinical diagnosis is less than 3 per cent for the group as a whole and about 10 per cent for the malignant component. It is unsafe to depend on a purely clinical diagnosis in such instances and excision of the tumor or area in question, often involving a quadrant of the breast or, when the involvement is greater a conservative total mastectomy is necessary. When the clinical diagnosis of carcinoma is presumptive the attack should be a radical mastectomy at once. The differential diagnosis and treatment of tumors of the breast rests on a concept of the so-called chronic cystic mastitis as an aberration of the cyclic changes in that organ associated with estrus, that is to say, it is a benign lesion. In the generalized form diagnosis is safe but in the types limited to certain areas in the breast or to a single tumor, exploration is necessary because the differential diagnosis from cancer cannot be made with sufficient security.

Operative Treatment of Stricture of Rectum—A case is presented in which a procedure was adopted that Lockhart-Mummery and Lloyd-Davies believe to be original and seems to offer an alternative to Hartmann's method of resecting the stricture. It gave a better result than could have been obtained by resection. It is not applicable in all cases of fibrous stricture of the rectum, as it is essential that free access should be obtainable to the whole of the strictured area. Since the operation does not involve opening the peritoneum, it is very much safer than a resection operation. The patient was given a low spinal anesthetic and then placed in the Sims position. The rectum was thoroughly washed out with a weak antiseptic solution and an incision was made in the midline posteriorly, extending from a point over the lower part of the sacrum to a point just behind the anal orifice. The coccyx was removed and the postrectal fascia divided. The rectum was then freely mobilized by stripping it from the pelvic wall on each side. In this way it was possible to draw down into the wound that part of the rectum containing the stricture. A considerable amount of dense fibrous tissue had to be divided before the actual rectal wall could be exposed and the stricture was then divided longitudinally into the rectum, the incision extending into healthy intestine both above and below the narrowed portion. Tissue forceps were placed on the edge of the rectal wound on each side in the middle of the longitudinal incision and the rectum was drawn open. A large rubber tube was next passed into the rectum through the anus, the upper end passing well above the strictured area. The incision in the rectum was closed transversely by interrupted catgut sutures, with the knots on the mucous side, and covered by a second line of Lembert sutures. The fascia was stitched over the line of suture and the skin was closed, a small drain being placed in the upper part of the wound. The drainage tube in the wound was removed in

twenty-four hours and the rectal tube in four days. Satisfactory healing took place except for a small sinus, which healed in a few weeks. On examination of the rectum no sign of stricture was present. A year has elapsed since the closure of the colostomy, and the patient's bowels open normally and regularly every day and there is no sign of the original stricture.

Posterior Segmental Block Excision of the Neck of the Bladder—Harris presents the operation of posterior segmental block excision of the neck of the bladder with primary closure in the belief that it is an improvement on the well recognized operations of cuneiform (or wedge) resection and of complete extirpation of the neck of the bladder. The operation has been carried out in thirty-three cases without mortality. After the base of the bladder is exposed by the same technic as the author employs for prostatectomy, the tip of the right forefinger is gradually but firmly insinuated through the internal meatus. Two fingers of the left hand are passed into the rectum and provide an invaluable point of counterpressure during this maneuver. Two deep traction sutures are placed in position, one on each side about half way round the dilated prostatic rim. Following this, at least three-fourths inch of the hindmost sector is excised. In order to carry out this excision two deep parallel vertical incisions are made, one on each side of the midline and reaching down to the level of the floor of the prostatic urethra. The intervening lip is then firmly drawn up by traction forceps and cut out deeply and cleanly in a transverse direction by sharp scissors. The bared base must be carefully examined and, if need be, trimmed up. It is important that no gross fibrous or adenomatous remnants be left at this site. The crosscut ends of the prostatic rim are next freely undercut on each side to permit of their complete retraction. Two deep hemostatic sutures are then passed on each side behind the two traction sutures that were inserted prior to the excision. These sutures also serve to turn in on each side the bared face of the crosscut ends, thus eliminating the raw surface. When hemostasis has been accomplished, retrigonization is carried out and completes the plastic portion of the operation. The anterior obliterative sutures employed after suprapubic prostatectomy are not required for this operation, as the anterior segment of the neck of the bladder has not been interfered with and there is no raw surface left to obliterate. A number 22 French rubber catheter is passed through the urethra into the bladder, and its end including the eye, is cut off after an opening has been cut about 1 inch behind the eye. The catheter is suspended in position by a silkworm intestinal suture. The bladder and abdominal wounds are completely closed and the silkworm intestinal suture is suspended to a small glass rod on the abdomen according to the author's practice after prostatectomy. The after-treatment is the same as that employed after prostatectomy.

Histidine Treatment of Peptic Ulcer of Lesser Curvature—Smith employed the histidine treatment of peptic ulcer in twelve cases that fulfilled certain criteria: (1) a history suggestive of gastric ulcer, (2) the exclusion of cases obviously surgical and (3) unequivocal roentgen evidence of ulcer of the lesser curvature. Ordinary diet was permitted without restriction. Daily injections of 5 cc. of a 4 per cent solution of histidine were given. No other form of treatment was used. Of the twelve cases, seven were treated in the wards in order to study them more carefully, and five were treated as ambulatory cases in private. The hospital patients were allowed to be up, and they assisted in various ward duties. Four private patients continued their ordinary occupations, and one was up and about but not at his work. The first symptom to disap-

pear was discomfort. This refers to the vague feelings of fullness, soreness, nausea and tastes in the mouth. Vomiting was almost immediately controlled, and before long pain ceased to be a disturbing factor. Loss of appetite was not a common complaint, but, when present, there was a speedy return of a desire for food. The patients soon had a better color, and their weight increased each week. In no case was there a failure to gain substantially in weight. In cases in which there had been gastric retention due to pylorospasm the emptying time improved. The better function was also seen in the relief from constipation. Definite flatulence was the most obstinate subjective symptom. In two cases, in which it persisted throughout the whole course of injections, it was completely relieved by the daily administration of two tablets each containing one-fifth grain (0.013 Gm) of histidine. Tenderness on palpation was present in all cases until several injections had been given, but the most refractory yielded after the twentieth dose. Striking roentgen improvement was observed.

Monocytic Leukemia—Mann describes a case of monocytic leukemia with an account of the necropsy and microscopic examination of the tissues, and he analyzes fourteen such cases. The history of monocytic leukemia may be divided into two phases. The first, lasting a few months, is marked by infection, progressive pallor and lassitude. The second, the beginning of which is often marked by ulceration of the gums and in which a stomatitis is almost invariable, consists of a rapid deterioration of the patient, often with further necrosis in the mouth. The spleen and liver are palpable in about half the cases, but the enlargement is rarely extreme. Enlarged lymph nodes other than those draining the infected area in the mouth are present only in less than half the cases. The second phase is associated as a rule with a rapid increase in the number of circulating white cells, a high proportion of which are mature monocytes. The case described is evidently a typical case of monocytic leukemia of the acute variety. The first subacute phase of progressive weakness and increased pallor lasted about five weeks and was followed by an acute terminal illness of a duration of six days. Blood counts showed typical mature as well as immature monocytes while the postmortem exami-

nation revealed leukemic infiltration in many organs, with reticular hyperplasia in the spleen and lymph nodes.

Headache as a Feature of Ménière Symptom Complex—Cohen reports eleven cases in which the picture of the Ménière symptom complex was present, with particular reference to headache. The nature of the headache did not appear to be characteristic, since it was variously described as sharp, dull, continuous, intermittent, throbbing, stationary or radiating. Its localization, however, seemed characteristically to be in the sagittal plane of the head (frontal, vertical, occipital or radiating in this plane). Headache is a more common feature of the Ménière symptom complex than tinnitus and should for this reason be more generally recognized as important in the diagnosis of the condition. The data of the cases bear more specifically on the neurologic aspects of the disorder. Of the eleven cases, in seven there were positive family histories for organic nervous system disease in the immediate line, in nine cases there were neurologic signs other than those referable to disease of the middle ear. It would appear, therefore, that an organic neurologic basis for this disorder is primary. It does not necessarily follow that the headache found in the Ménière symptom complex is also primarily neurologically conditioned, since it may arise in association with circulatory changes. On the other hand, the fact that in seven of the cases headache was present from the beginning of the symptomatic stage, if not before, argues for a common origin of this symptom with the others (vertigo, tinnitus, deafness). The fact that the headache was localized would argue against circulatory dysfunction as its primary cause. The sagittal headache is localized in and/or over the surface projection of the falx cerebri and the tentorium cerebelli. These anatomic structures are formed by a reduplication of dura mater. Why headache has this localization in this condition, the author states cannot be accounted for on the basis of his data.

Studies on Etiology of Scarlet Fever A. Imamura H. Ono T. Endo and I. Kawamura—p. 341

Experimental Serotherapy of Smallpox—Yaori obtained an active antiviral serum by repeated subcutaneous inoculation into the goat of the purified vaccinia virus, the inoculations were made with successively increasing amounts of vaccinia virus over a period of from three to seven months, with an interval of five days. Provided the amount of the purified vaccinia virus inoculated into the marginal vein of the ear of rabbits (weighing 1,000 Gm.) was sufficient to produce a generalized skin lesion, a generalized vaccinia occurred on the fourth or fifth day, but in case of animals weighing about 2,000 Gm. the occurrence of generalized vaccinia was postponed until the seventh day. In animals thus inoculated with the vaccinia virus, if later treated with the antivaccinal serum either intravenously or intramuscularly, the appearance of eruptions is completely or strongly inhibited. The effect of the serum appears not in the least different according to the divergent periods of its administration, i. e., from one to seventy-two hours after the infecting inoculation. Monkeys (*Macacus fuscatus* and *rhesus*) inoculated with a strain of variola virus by the intravenous route develop a generalized lesion five days later. The appearance of the eruption resembles human smallpox. The eruption proceeds to papule, vesicle and pustule, further scab formation and its falling off, and scars remain at least until the twenty-seventh day, as depilated white spots. In a monkey thus previously infected with a variola virus, if injected with the antiviral serum intramuscularly while it is developing papules or vesicles the eruptions are so influenced as never to proceed beyond the pustule stage, and quick drying and falling off of scabs set in and the eruption clears up completely. The quick disappearance of disease symptoms, recovery of the well being and appetite and an increase in body weight are evident.

- *Paralysis of Vasomotor System by Volatile Industrial Solvents L. Dautrebande—p 1081
Distribution and Evolution of Vitamin C in Body A Giroud and C P Leblond—p 1085

Vasomotor System and Industrial Solvents—Dautrebande discusses the mode of action of the volatile industrial solvents, such as benzene, petroleum ether, amyl acetate and cellulose varnish. Most of his observations were made on anesthetized dogs. He concluded that the volatile solvents possess the property of paralyzing the vasomotor system and that this intoxication is rapid like detoxification. The action does not affect the centers but bears on the periphery and especially the smooth muscle of the vessels. Both in the intact animal and in isolated organ preparations reversibility of the effect is dependent on the duration of action of the poison. In general, if the intoxication by benzene does not exceed two minutes, the isolated organ renews its spontaneous contractions if placed in pure Ringer's solution. If longer than three minutes, this does not occur. This paralyzing action at the level of the muscle itself affects all the muscles approximately equally.

- *Degenerative Lesions of Liver and Insulin Resistant Diabetic Coma M Labbé R Boulin and Balmus—p 1105
Intoxication by Polypeptides P Cristol—p 1107

Lesions of Liver and Diabetic Coma—Labbé and his co-workers report observations of the liver in four fatal cases of diabetic coma. In all instances the patients were in complete coma with abolition of reflexes. The urine regularly showed glycosuria and diacetic or beta-oxylbutyric acids. The blood constantly presented a low alkali reserve. In spite of strong doses of insulin, the patients all died the same day or the next. In all cases glycosuria persisted throughout. Three of the patients showed symptoms of cardiac collapse. Renal lesions involving principally the glomeruli, largely old and usually slight, were found. The liver changes were more important and consisted in increase in volume of the organ, which weighed from 1,950 to 3,400 Gm., disappearance of the lobular structure and changes in the cells involving fatty infiltration in two cases and spongy aspect in the other two, the nuclei being often absent or poorly colored. The authors believe, therefore, that there is thus a fourth type of hepatic lesion in diabetes. It is possible, though not confirmed, that renal and hepatic insufficiency constitute important factors in insulin resistance and are accountable for part of the mortality from diabetic coma.

- *Staphylococcus Anatoxin and Its Use in Specific Treatment of Certain Staphylococcal Disorders G Ramon A Bocage R Richou and P Mercier—p 1137
*Vaccinotherapy by Staphylococcus Anatoxin P Nélis—p 1141

Staphylococcus Anatoxin—Ramon and his collaborators report the results of treating certain local staphylococcal infections with toxoid. The toxin was obtained by growing the staphylococci in a semisolid medium composed of bouillon and gelose. This medium, with or without sugar, is inoculated with a toxigenic strain. A gaseous current consisting of 80 per cent air and 20 per cent carbon dioxide is passed over the culture. After five days of incubation at 37 C it is filtered, the filtrate containing the toxin. The antigenic power of the toxin can be tested in vitro. To this bouillon, formal is added (4 cc per liter) and left in the drying oven at 39 or 40 C for two weeks. The important properties to determine are the innocuousness and the intrinsic antigenic power. The latter is expressed in antigenic units of flocculation. The patients were treated first with injections of diluted and later of the undiluted toxoid. In the majority of instances both were well tolerated. Local reactions were commonly slight and transitory. General symptoms occurred less commonly but were not severe. Focal reactions were rare. The therapeutic effect was encouraging from the beginning. Forty-two patients having obstinate furunculosis were treated and thirty-seven recovered. Of twenty-two having simple chronic furunculosis and of seventeen having incidental furunculosis, all recovered. Nineteen patients

of twenty-three having pustular acne recovered. Six patients with sweat follicle infections and perionyxis recovered. The authors conclude that the results are satisfying.

Vaccinotherapy by Staphylococcus Toxoid—Nélis discusses the use of toxoid in various staphylococcal infections. His results especially in furunculosis were usually good and he believes that this method of vaccinotherapy is superior to all other methods of treatment heretofore employed in local staphylococcal disorders.

Intravenous Injections of Insulin Clinical and Experimental Study A Gnarino and M Stellatelli—p 1132
Hemotherapy Morphologic Picture of Blood L Gipperich—p 1156
Functions of Heart and Electrocardiogram After Effort in Bronchial Asthma E Castellani and Lina Gozzi—p 1175
Mediastinal Hernia Cases G Reggiani—p 1201

Trimethylamine in Urine—Monasterio made determinations of the contents of trimethylamine in urine in normal and in certain pathologic conditions and concludes that trimethylamine is a constituent of urine that under normal conditions varies between 0.0009 and 0.00303 Gm per hundred cubic centimeters of urine and between 0.00108 and 0.003412 Gm in the total amount of urine eliminated during twenty-four hours. Trimethylamine is a product of the metabolism of certain phosphatides and betaines. Its origin in the putrefaction of lecithins, choline and certain food proteins in the large intestine is scanty. Probably synthetic processes of the substances, on the one hand, and oxidative or hydrolytic processes, on the other, are involved in the production of urinary trimethylamine. There is no parallelism between trimethylaminuria and indicanuria. The elimination of urinary trimethylamine increases in normal conditions after abundant ingestion of either meat or lecithins and in pathologic conditions that stimulate the catabolism of the phospholipins and body proteins, such as diseases of the nervous system, diabetes and cachectic diseases. Its increase in diseases of the liver is explained by the fact that the defective functions of the organ result in insufficient catabolism and the use of the amines in the processes of synthetization of choline and lecithins.

- Studies on Action of Resuscitation Measures in Experimental Asphyxia S Koeppe—p 1131
*Occurrence of Variants of Spirochaeta Icterohaemorrhagiae (Spirochete of Weil's Disease) H Schlossberger J Grillo and L Scheele—p 1133
Carbohydrate Metabolism of Warm Blooded Animals During Muscular Exertion E Jökl—p 1139
*Behavior of Amount of Bile Pigment in Blood in Intensive Muscular Exertion L Stanoević and Sava Petrović—p 1146

Variants of Spirochaeta Icterohaemorrhagiae—In the examination of numerous serums from patients with infectious jaundice for the presence of agglutinins and lysins for Spirochaeta icterohaemorrhagiae, Schlossberger and his associates were able to corroborate the observations of Baermann and Zuelzer, namely, that the majority of serums react with various strains of Spirochaeta icterohaemorrhagiae but that there are some serums that in the agglutination and lysis experiments give positive results only with a few of the strains, occasionally only with one. Repeated tests on the serum of the same patient (withdrawn at different times) occasionally reveal an increase in the number of strains that can be influenced in the agglutination and lysis tests. The agglutination and lysis experiments indicate that, in examining serums from patients in whom an infectious jaundice is suspected, it is necessary to test a larger number of different strains of Spirochaeta icterohaemorrhagiae in order to obtain reliable results. Moreover, the results of the experiments correspond with the observation that the potent monovalent antisera against infectious jaundice which are obtained by the immunization of rabbits influence many but not all the strains of Spirochaeta icterohaemorrhagiae. On the basis of these observations, as well as of prophylactic experiments with monovalent antisera (passive immunity) and of active immunization experiments with monovalent iodine and formal

dehede vaccines, it may be assumed that the spirochetes of Weil's disease cannot be differentiated into sharply defined types, but rather that the antigen apparatus of the various strains is probably composed of different partial antigens and that the distribution of these partial antigens differs in the various strains. The authors conclude that in the serotherapy of infectious jaundice only the polyvalent immune serums give any prospect of therapeutic efficacy.

Bile Pigment in Blood in Muscular Exertion—Stanojevic and Petrovic state that it is generally assumed that under physiologic conditions the spleen is the source of the bilirubin that appears in the blood. For this reason, some investigators succeeded in producing an increase in the bilirubin content of the blood by causing contraction of the spleen by means of epinephrine injections. Since muscular exertion leads to contraction of the spleen, the authors decided to investigate the behavior of the bilirubin content of the blood during and after muscular exertion. Their studies were made on healthy young men who were not accustomed to intense muscular exertion. The bilirubin was determined according to the method of Hymans van den Bergh by means of Autenrieth's colorimeter. Specimens of blood were withdrawn before, during and after muscular exertion. It was found that intense muscular exertion increases the bilirubin content of the blood by from 20 to 45 per cent. The increase becomes noticeable within the first few minutes of the exertion and reaches its maximum at the end. During the rest period the bilirubinemia decreases gradually, but in the majority of cases it does not entirely return to its initial value even after a prolonged rest. If the muscular exertion is resumed, the bilirubin content increases again, but it is now less than during the first exertion. The experiments indicated that the intensity and the duration of the exertion influence the increase in the bilirubin content.

*Case of Rumination Lotte Sylla—p 1011

*New Method for Testing Pectoral Fremitus D Sucić—p 1012

Rumination—In the case reported by Sylla a woman, aged 26 complains that about twenty minutes after a meal her food comes up again. She chews it again and then swallows it, but some of the food is extremely bitter and is expelled by the patient. Particularly after sweet foods she has an unpleasant feeling of pressure in the region of the stomach. She has had this disorder since her twelfth year and for several years has had recurrent attacks of severe gastric spasms. The roentgenologic examination disclosed an enlarged stomach, which after filling showed a peristaltic wave in the upper portion from which retroperistaltic ascending waves could be observed. The raising of the food was effected by the action of the abdominal muscular pressure by the action of the diaphragm by retroperistaltic waves and by the opening of the cardia following eructation of air. The patient's condition could be improved by gastric lavage and by giving small quantities of food at short intervals. In this case the disorder was apparently a combination of aerophagia and rumination. The cause of rumination is not fully understood. The older writers consider some cases hereditary and others the result of a neuropathic constitution. In the reported case there were indications for neither of these origins.

New Method for Testing Pectoral Fremitus—Sucić shows that pectoral fremitus together with bronchial respiration and bronchophony, make up the triad of symptoms by means of which an abnormal sound permeability of the pulmonary parenchyma can be detected. To be sure bronchial respiration is the most important of the three in the recognition of infiltrative processes in the pulmonary parenchyma but although bronchophonia and pectoral fremitus have as a rule only confirmative value in connection with the results of the

bronchial respiration, there are some cases in which they furnish the most important auscultatory signs. The author discusses the sound mechanism of pectoral fremitus and shows that when, as is usually the case, pectoral fremitus is elicited by letting the patient speak loudly, it is essential that the vocal cords function properly. However, in patients with aphonia, such as those who have a laryngeal stenosis or who have undergone a laryngectomy or a tracheotomy, it is impossible to elicit the pectoral fremitus by letting the patient speak loudly. The author found that hawking or coughing will produce a clear pectoral fremitus. He found that in patients with normal vocal cords hawking is more effective, while in patients with aphonia, particularly in those who have undergone tracheotomy or laryngectomy, better results can be obtained by urging the patient to cough. The author illustrates this with several case reports and explains the mechanism that is involved when pectoral fremitus is elicited by hawking or coughing.

Hypophyseal Disturbances Following Pregnancy—Seitz mentions factors that indicate the dominating position of the hypophysis among the endocrine glands and in the metabolic processes and as an explanation he cites the fact that through the infundibulum the hypophysis is in direct connection with the diencephalon the site of the sympathetic centers. Considering the great changes that take place in the organism during pregnancy, it is not surprising that the hypophysis is to a great extent involved in these changes. It has been determined that the hypophysis becomes considerably enlarged during pregnancy. This hypertrophy involves chiefly the anterior lobe and especially the main cells, whereas the acidophils and the basophils are not increased. For this reason the main cells have been referred to as pregnancy cells. The author gives his attention to changes and disturbances that occur during pregnancy and after delivery the symptomatology of which indicates a connection with irregularities in the hypophyseal function. He points out that an abnormal function of the hypophysis may become manifest during pregnancy in that the woman's hands, feet nose and chin become enlarged. Mild forms of this acromegaly of pregnancy and even a severe form are occasionally observed. The author noticed a considerable number of women who had polydipsia and polyuria during their pregnancy, and he describes one case in which acromegaly and diabetes insipidus occurred during pregnancy. He discusses hypophyseal disturbances that develop after delivery. He calls attention to the so called lactation atrophy of the uterus and expresses the opinion that lactation is only a contributing cause and that the hypophysis plays an important part in this phenomenon. He thinks that a severe hyperinvolution and atrophy of the uterus after delivery is the first and mildest manifestation of an excessive involution of the hypophysis. Then he gives his attention to the hypophyseal obesity that occasionally develops after delivery. This condition is usually accompanied by oligomenorrhea or by amenorrhea, and the author considers it the result of an excessive involution of the hypophysis. This assumption is corroborated by the fact that hypophyseal preparations exert a favorable influence on this condition. Estrogenic substance also seems to have a favorable effect, however, its effect is not as satisfactory as that of the hypophyseal preparations. Another disorder that may result from a hyperinvolution of the hypophysis is emaciation. The author concedes that it may appear contradictory to ascribe obesity and emaciation to the same cause, but he asserts that the contradiction is only apparent, there being only a difference in the degree of the hypophyseal changes. The hypophyseal emaciation that develops after delivery is really a mild abortive form of Simmonds' disease. The author describes a case history in which ovarian

preparations proved ineffective but the administration of hypophyseal preparations was followed by the disappearance of the symptoms. Whereas the aforementioned conditions were caused by a hypofunction of the hypophysis as the result of hyperinvolution, there are also cases in which disturbances result from a retarded or insufficient involution of the hypophysis. In this connection the author mentions certain cases of subinvolution of the uterus with hemorrhages. In such cases curettage is usually effective.

*Is Rickets in Spasmophilic Children with Tetany Always in Same Roentgenologically Demonstrable Stage? E. E. Joepchen—p. 217

Aspects of Heerfordt's Syndrome (Uveoparotid Fever)—Haferkorn points out that Heerfordt's syndrome, in which fever, iridocyclitis and parotitis are the most noteworthy symptoms, occurs mostly in children and young persons. He describes a case of his own observation. In a boy, aged 13, there developed in rapid succession paralysis of the three branches of the facial nerve, swelling of the parotid gland and iridocyclitis. The patient also had polydipsia and polyuria. The author thinks that the polydipsia was the result of a deficient secretion of the parotid gland, for the existence of diabetes insipidus could be excluded because of the inefficacy of the hypophyseal preparations and on the basis of the sodium chloride tolerance test. The swellings of the parotid gland and of the bronchial lymph nodes yielded to roentgen therapy. In discussing the etiology of the uveoparotid gland, the author points out that Heerfordt assumed an infectious-toxic origin and rejected a connection with mumps. However, several other investigators gave consideration to the problem of chronic mumps, for in a number of cases, the reported case included, an attack of mumps preceded the development of Heerfordt's syndrome. Other authors assume a connection with tuberculosis. In the few cases in which a histologic examination of the eyes was done, the diagnosis of tuberculosis could be corroborated. In the author's case, roentgenologic examination of the lung revealed signs indicative of tuberculosis of the bronchial lymph nodes. Moreover, a calcified tuberculous focus was found in the abdomen and an excised piece of the parotid gland showed, on histologic examination, caseous granulation tissue, which doubtless was of tuberculous character.

Articular Manifestations in Infantile Leukemia.—Fuchs shows that the diagnosis of leukemia is difficult during childhood because during early childhood there is a physiologic lymphocytosis. Then there is a certain type of obese children in whom the spleen is palpable and who retain a lymphocytosis longer than is normally the case. Moreover, children occasionally have a tendency to respond to an infection with a lymphatic reaction. These factors show that in children the differential blood count may meet considerable difficulties when the possibility of a lymphatic leukemia has to be decided. The author relates the history of a girl, aged 3. The involvement of the joints made the diagnosis still more difficult. He describes another case with articular involvement. In this child there existed a lymphatic leukemia, the most noteworthy symptoms of which were severe pains in the joints, fever and inflammatory swelling of some of the joints. In view of these symptoms, articular rheumatism was first thought of. However, when swelling of the lymph nodes developed, a blood disease was suspected and the disorder was diagnosed as leukemia. In both cases areas of lesser density were noticeable in the bones, and the author considers these as characteristic for leukemia. Both children died, but, since necropsy was done in neither of them, there is no definite proof of the leukemic nature of the bone disorder. However, on the basis of reports of other investigators, the author concludes that

these bone changes were the result of a destruction of the normal bone structure by proliferating leukemic tissues. He thinks that the pains in the joints were likewise the result of leukemic proliferations in the *juxta-articular* portions of the bone. He reviews the literature on cases of leukemia that presented the aspects of febrile articular rheumatism and discusses the differential diagnosis, pointing out that, although osteitis fibrosa and Gaucher's disease may present similar roentgenologic aspects, their clinical aspects differ from that of leukemia. He concedes that the differentiation from acute articular rheumatism and from Still's disease may present considerable difficulties.

Relations Between Rickets and Tetany—Joepchen calls attention to the fact that studies by Rominger and his associates disclosed that, as the cure of rickets begins, larger quantities of phosphorus are retained, while the calcium retention is still insufficient. Thus the blood presents at this time the typical distribution of minerals that is found in tetany, and Rominger concluded from this that the tetany of children develops on the basis of rickets and is an accompanying symptom of a beginning cure of the metabolic disturbance of rickets, that tetany is, so to speak, the curative crisis of rickets. Gerstenberger maintained that an interruption of the antirachitic treatment leads to tetany. At any rate, he too thought that improvement in the rachitic bone process is demonstrable when tetany develops. The theories of both these investigators were corroborated by the observation of Hulschinsky and others, who, in the roentgenogram of the rachitic child with tetany, noticed calcium deposits in the preparatory calcification zone. However, since these authors had studied only a small material, the author decided to verify the observations on a larger material. All children with tetany who came to his clinic were subjected to careful roentgenologic control. He examined thirty children with tetany and made comparative studies on thirty children who had rickets but were free from spasmophilic manifestations. He observed the presence as well as the absence of calcium lines in children who had only rickets and in children who had rickets and spasmophilia. He was unable to detect a characteristic roentgenogram in children in whom rickets was combined with spasmophilia and considers it unjustifiable to accept the roentgenograms that show a calcium line as indicative of a curative phase of rickets. He thinks that this calcium line may also be the manifestation of incompletely developed rickets. He concludes that there is no roentgenologic proof that spasmophilia is a curative crisis of rickets.

Bronchial Cancer of Smokers—Lickint cites reports which indicate that carcinoma of the organs which are within the so-called smoke tract (lips, oral cavity, larynx and so on) are more frequent in smokers than in nonsmokers. Then he gives his attention to bronchial carcinoma. He shows that in some smokers the bronchi are within the so-called smoke tract and that, as the habit of inhaling the smoke increases, the incidence of bronchial tumors increases likewise. He admits that bronchial carcinoma occurs also in nonsmokers and he recognizes that this indicates the existence of cancerigenous factors other than tobacco. Moreover, he concedes that not all bronchial carcinomas which develop in smokers are necessarily caused by tobacco, but he believes that tobacco is the chief cause in the majority of cases. In many cases the effect of tobacco probably concurs with other cancerigenous factors. The author reaches the conclusion that it cannot be doubted that tobacco smoke plays a part in the etiology of bronchial cancer and he thinks that the inhalation of tobacco smoke should be discouraged. Moreover, in persons whose family history seems to indicate a predisposition to cancer, smoking as such should be advised against.

Essential Acetonemia of Children—According to Sporn acetonemic conditions are relatively frequent during childhood. Aside from the symptomatic forms of acetonemia that appear in the course of many infectious diseases during starvation in diabetic acidosis and in other conditions, there is the essential form, namely, the periodic or cyclic vomiting with acetonemia. In the latter condition, attacks of uncontrollable vomiting occur after intercurrent periods of complete health. These attacks appear suddenly or are preceded by several days of indisposition. During the attacks, which persist for several days or a week, the children present a wasted appearance and are unresponsive although conscious, their eyes are sunken and, as a result of considerable dehydration, their skin is slack. The respiration is forced and the expiratory air has an odor of acetone. The vomit at first contains remnants of food but later, after the intake of food has become impossible it consists chiefly of mucus and water with occasional traces of bile or blood. Occasionally the children complain of abdominal pains and often there is constipation. The liver is usually slightly swollen and the urine contains considerable quantities of acetone bodies. After several days the vomiting ceases and the other symptoms disappear. A new attack appears after several weeks or months. In addition to these typical attacks of periodic acetonemic vomiting there are also less characteristic rudimentary forms. These also recur periodically but they are not quite so severe. The author observed a number of cases of essential acetonemia, which differed from the described condition chiefly in that they lacked periodicity. He describes the clinical histories of several of these cases. No causal factor of the acetonemia could be found in any of these cases. The consciousness of the children became suddenly impaired. In some cases there was complete loss of consciousness and areflexia. Usually there was vomiting, with occasional attacks of convulsions. The respiration was forced, the expiratory air had an odor of acetone and the urine contained acetone. The severe symptoms disappeared, as a rule quite rapidly, consciousness returning after a day and the other symptoms disappearing within a few days. In addition to the lack of periodicity, this disorder differs from that described in the first part of the paper in that the loss of consciousness is more pronounced than the vomiting. Although the pathogenesis of these essential acetonemias is not completely understood, they are favorably influenced by the administration of carbohydrates in the form of dextrose.

Anomalies in Position of Teeth H Pilcher —p 1019

Changes in the Large Bronchi—Fleischner discusses the significance of changes in the large bronchi for various pathologic conditions of the lung. He mentions bronchiectasis, the so-called congenital sac lung and honeycomb lung, hemoptyses of obscure etiology, temporary atelectasis, patients who eliminate tubercle bacilli and bronchial obstructions. On the basis of these observations he attempts to explain the pathogenesis of

the early phthisic infiltrate and of the temporary infiltrations. He discusses a ventilatory disturbance that is likely to develop when there exists only a slight stenosis of the bronchus. He thinks that this disorder is quite often the cause of bronchiectasis and that many and perhaps the majority of the cystic or honeycomb lungs observed in adults are the terminal stages of saclike bronchiectases. It would be a mistake to speak of congenital deformities in conditions of this kind, and instead of applying the term sac lung or honeycomb lung, which apply to congenital disorders, it would be better to use the term polycystic disease of the lung. The author shows that hemoptyses originate occasionally in the large bronchi, either in benign tumors, granulation tumors, hyperplasias of the mucous membrane of the bronchi or changes near tuberculous or anthracotic lymph nodes. Reactions in the surroundings of such foci of the lymph nodes, which usually belong to the primary complex, in the form of infiltration of the bronchial wall and perforation with complete or partial expulsion of the focus, lead by way of a bronchostenosis to atelectases and to atelectatic pneumonias of the corresponding pulmonary lobes. There are also perforations without atelectases, they explain the elimination of tubercle bacilli in persons without demonstrable tuberculous changes in the lungs. Complete cicatricial closure of a bronchus produces atelectatic densification of the corresponding pulmonary lobe, while incomplete closure favors the development of suppurating processes beyond the stenosis. It may be assumed that from bronchial perforations of tuberculous foci of the lymph nodes there frequently derives the material that will form the initial foci of the bronchiogenic phthisis. Many foci of the "exudative type," particularly many of the infiltrates along the edges of the lobes, are not really tuberculous foci, nor are they perifocal reactions but rather atelectatic engorgements.

Compression Myelitis in Idiopathic Osteospathyrosis—Deutsch describes the various conditions that favor the development of a compression or transverse myelitis, especially those in which a pathologic bone structure of the vertebral column exists. He discusses chiefly osteospathyrosis, which often produces no subjective symptoms but may cause spontaneous fractures of the vertebrae. He gives a detailed description of the case history of a woman who, since early childhood had repeated fractures, and this together with the blue scleras, the hardness of hearing and the calcium deficiency of the bones does not leave a doubt that osteospathyrosis, or at least a quiet similar disorder, existed. The case is worthy of attention especially because of the myelitic manifestations, which were the result of compression. The true nature of the disease was not detected until a roentgen examination was made following the development of the nervous symptoms, which were produced by the spontaneous fracture of a vertebra. The author calls attention to the similarities and differences between osteogenesis imperfecta and osteospathyrosis and reviews several other interesting cases of osteospathyrosis that have been observed by other investigators.

Suprasellar Tumors—In this summary discussion of the tumors of the suprasellar region, Schüller calls attention to the fact that in recent years the knowledge of the suprapituitary structures has greatly advanced but that there are still a number of unsolved problems particularly as regards the tumors of the suprasellar region. He points out that the most frequent and also the most dangerous symptom of suprasellar tumors is a bilateral involvement of the optic nerve but that quite frequently this symptom is not correctly interpreted, which may be due to the fact that it is often the only symptom of the tumor. He describes the various forms of suprasellar tumors and their symptomatology, particularly hypophyseal tumors and the disorders caused by them. He discusses the differentiation of the suprasellar neoplasms from such conditions as epidemic encephalitis, multiple sclerosis, basal syphilitic meningitis, tabes with blindness, traumatic hemorrhages in the region of the chiasma and internal hydrocephalus of the third ventricle, and from remote symptoms of other endocranial tumors and the disorders of endocrine glands other than the hypophysis. In discussing the treatment of suprasellar tumors, the author points out that in some tumors operation is impossible. Then he mentions several of the surgical procedures and irradiation and

shows that certain disturbances caused by the impairment of the endocrine function of the hypophysis may be influenced by substitution therapy in the form of enteral or parenteral administration of endocrine preparations

New Treatment of Sprains—Kraus mentions the various therapeutic methods that are employed in sprains and shows that the best results are usually obtained in persons who have received no particular treatment but who had the energy to disregard the pain and at once begin with the active exercise of the joint. He points out that among actors it is customary to apply alcohol to a sprained joint and hold it over steam. This stops the pain and makes movement possible. The author followed this suggestion and found that the application of ethyl chloride produces anesthesia of the articular ligaments and that active movements during this anesthesia counteract the stiffness of the joint. He describes the procedure he usually follows. After the diagnosis and roentgenoscopy, he determines the painful point and applies ethyl chloride to it. Freedom from pain is soon established and is protracted by dropping a mixture of ether-alcohol-acetone (100 parts each) and camphor (20 parts) on the joint. Then the patient is urged to make active movements, chiefly in the direction of the greatest functional impairment, which of course has to be determined before anesthesia is induced. The treatment is continued for from ten to twenty minutes and is repeated several times. The patient is urged to apply at home three times daily the alcohol and steam treatment and to do further exercises. The author recommends the treatment for all new sprains that come under the physician's care in the first week or two following the accident and for old relapsing sprains. The treatment is contraindicated in cases in which the articular ligaments are severely torn, or when an intra-articular exudate is present. He warns against excessive freezing with ethyl chloride. Then he reports several cases in which he employed the treatment. He thinks that the method may eventually prove helpful in the after-treatment of fractures as well as for diagnostic purposes and for painless reduction of incarcerated menisci.

- Uterus Bicornis in Obstetrics S Zanela —p 1879
- Tubal Rupture Simulating Intra Uterine Abortion W Briem —p 1891

Puerperal Mastitis—Puppel criticizes the treatment of mastitis by means of Bier's stasis and puncture incisions as unsatisfactory and stresses that, as in any other inflammatory process, the inflamed breast should be immobilized. He does not consider lactic stasis dangerous in mastitis, as some obstetricians do, because then mastitis should appear in abortions and in premature births. He thinks that external infection is the most frequent cause of mastitis, pointing out that rhagades are present in nearly all cases. The smallest fissure is sufficient to provide a port of entry for pathogenic organisms. For this reason it is advisable to take preventive measures as soon as fissures or rhagades appear. The breast should be immobilized and the child should not nurse, but the milk should be carefully pressed out. After twenty-four or forty-eight hours the fissures are healed sufficiently to let the child nurse again with the aid of a protector. Similar measures are resorted to if mastitis with high fever develops. The breast should be bound up, an ice bag applied and a vaccine preparation administered. The milk is pumped out only if the breast is overfilled. Nursing at the breast should not be resumed until fever has been absent for several days and after all signs of inflammation have disappeared. Since the author employed these measures, the mastitides that require surgical intervention have decreased greatly. That continuous nursing and puncture incisions are not advisable he observed in cases in which treatment was first given outside his clinic. He considers cessation of nursing also advisable for the sake of the infant, pointing out that the child may become infected. He cites a case in which continued nursing during mastitis resulted in a fatal septic pleuropneumonia of the nursing. The time at which incision should be done is largely determined by the type of the mastitis, whether a subareolar abscess, infiltration of a lobe, deep abscess formation or retro

mammary phlegmon. The author considers the latter condition most dangerous and requiring a wide opening. In these cases it is inadvisable to wait for fluctuation of the process or the positive outcome of an exploratory puncture. He thinks that in all cases in which it seems impossible to avoid abscess formation the incision should be made early so as to provide a discharge for the inflammatory products, because prolonged conservative treatment may lead to the destruction of large portions of the breast.

- *Renal Injury in Traumatic Shock E Husfeldt and T Bjerling —p 781

Renal Injury in Traumatic Shock—Husfeldt and Bjerling report two cases of marked traumatic shock following fracture of the pelvis and massive contusions in which blood transfusions resulted in improvement but death from uremia occurred one week after the accident. They could not determine whether the renal injury was due to local circulatory disturbances during the state of shock, leading to irreparable injury of the renal tissue, or whether a constant resorption of substances from the bruised tissue took place after the shock, exerting a direct toxic influence on the renal epithelium or maintaining a spasm in the blood vessels. They find the last-named assumption supported by (1) the remarkable emptiness of the glomerulus vessels on microscopic examination, (2) the surprisingly slight histologic changes in the kidneys, (3) the increased blood pressure noted as early as the day after the accident and (4) the results of function tests, showing that the disturbance did not appear until three days after the shock, which is incompatible with the idea of injury to the renal parenchyma during the state of shock itself.

- *Hemoglobin Content of Blood and Number and Volume of Red Blood Corpuscles in Healthy Men and Women L L Linneberg and H Schartum Hansen —p 832
- Resorption and Elimination of Iron Under Normal Conditions R Nicolaysen —p 842

Hemoglobin Content of Blood—Among fifty-one men, Linneberg and Schartum-Hansen found an average of 5.27 million red blood corpuscles per cubic millimeter and a hemoglobin content of 113 per cent, corresponding to 156 Gm of hemoglobin per hundred cubic centimeters of blood, or an oxygen binding of 20.9 per cent. Averaging their results with those of Jervell and Warburg gives 5.395 million red blood corpuscles per cubic millimeter and 115 per cent of hemoglobin, corresponding to 15.9 Gm. of hemoglobin per hundred cubic centimeters of blood, or an oxygen binding of 21.3 per cent. Among sixty women the average was 4.49 million red blood corpuscles and 102 per cent of hemoglobin, corresponding to 14.06 Gm of hemoglobin per hundred cubic centimeters of blood, and the hemoglobin content varied from 107.4 in the summer to 96.1 in the fall. Normal limits for men are set at between 99 and 135 per cent of hemoglobin and from 4.7 to 6.3 million red blood corpuscles, while for women values less than 90 per cent and more than 12.4 per cent of hemoglobin and less than 3.6 and more than 5 million red blood corpuscles are regarded as usually pathologic. The authors state that for both sexes the average hemoglobin content per erythrocyte is 30 or 31 micromicrograms, the content varying from 27 to 34 micromicrograms, and the average volume per erythrocyte is 85 or 86 cubic microns, the volume varying from 76 to 93 cubic microns. An anemia with more than 31 micromicrograms of hemoglobin per erythrocyte is hyperchromatic, one with less than 27 micromicrograms being hypochromatic. Color index and volume index are considered superfluous when such characteristic values as hemoglobin and volume per erythrocyte are available. The necessity is stressed of having a hemometer standardized by oxygen determination or other exact method so that the number of grams of hemoglobin per hundred cubic centimeters of blood that corresponds to 100 per cent on the hemometer is known.
